If, instead of such a shaving, the metal comes off in chips, the tool cannot be considered satisfactory. At the same time, a perfect shaving equidistant between the coils is not to be expected, unless the feed is automatic, as it is in reality what may be termed an unwound screw, whose threads would not be evenly cut by hand-feed with the slide-rest. It is, however, difficult to state, with certainty, to what particular defect of form or position of edge any unequal or broken-up shaving may point. As regards the finish of the surface left by the tool, Mr. Haydon's own remark is that it should be so brilliant that the slightest touch of the finest emery-cloth would spoil it. In most cases there will be first a coarse or roughing down cut, and then a finishing one with fine feed, although Mr. Haydon's theory was in favour of leaving a perfect surface from the first cut; in fact, that such surface was the natural result of an efficient tool even with a coarse feed and deep cut. Certainly a great deal of work can be sufficiently finished at one cut because the following edge always leaves it smooth and bright, but when it is an object to get as perfect a surface as possible, the tool edges should first have a final touch on the oilstone, and then a finishing cut should be taken with a fine feed, using soap-and-water as a lubricant, and this should flow freely from a drip-can, travelling with the tool slide. Means must be taken, of course, to catch the surplus water, which may be returned to the can after having the dirt and chips strained out of it. Mr. Haydon's sketch of drip-can set up on a steel support screwed into the pillar of the tool post I copy bodily, as no plan can answer better. The Willis tool holder is also shown made correctly, which is not always the case. The conical, or rather hemispherical, washer C is often omitted, as well as the lower triangular plate H but both are of real use, as the washer allows the plate A a certain amount of adjustment, while it nevertheless conveys the pressure of the screw and nut above it to the plate and tool. The lower plate forms an abutment for the side of the tool shank or bar at K, assisting in placing it rapidly in position. The screw passing through A enters a recess in H, and the whole turns as one piece with A. The most important detail, however, is that which is often wholly overlooked—viz., that the end A of the triangular clamp should be twice as long as B measured from the centre of the pillar. I have bought rests in which the two were equal. I have casually glanced at some details of this excellent tool-holder because it chances to be introduced with the drip-can; but I have not considered it necessary to give plan drawings, as the apparatus is pretty generally known. The drip-can itself exemplifies very well indeed the peculiar knack which Mr. Haydon has of adapting to his purpose the odds and ends so readily obtainable. I believe I am right in saying that the component parts in this case were a preserved-milk tin, part of a funnel, and a gas tap, to the latter of which was soldered the siphon-shaped bit of brass tubing shown by the dotted lines, which is intended to prevent dirt from being carried to the orifice of the tap. The tap itself is omitted, probably by accident, as it is very convenient; but the original of this drawing, copied by a "graph," is now very faint indeed, and I think I can detect a shadow or ghost of a tap handle. I have little doubt that it was once visible. The supporting pillar of the sliding block, which supports the rod and ring, is screwed into the pillar which forms the centre of the Willis holder—a very capital place for it. When not in use, the can may be swung back out of the way, or the can itself and its rod and ring can be instantly removed, leaving the pillar standing. Mr. Haydon used the drip-can much more than I do myself, because I have a great dislike to the "mush" and "mess" which I should call inseparable from it, were it not that in his hands no such disagreeables were ever in existence, as he was the cleanest workman I ever saw. Still, a great deal of work can be done without lubricants, except in the final cut which is to leave the surface in a state of perfect finish.

It does not appear to me that there is much more to be said upon the present subject, the object of these remarks being chiefly to call the attention of recent subscribers to the matter, which is one of great interest and importance. Every aspirant to the metal-turner's craft finds himself at sea as soon as he attempts to work with fixed tools in the slide-rest, and when some of us were young the battle had to be fought on very unequal terms, except with those who, living in London, were blessed with the advantages of King's College school and workshop. Now it is, at any rate, possible to learn why and how a certain form of tool answers better than another, and, when the principles are grasped, practice will soon follow with every prospect of success. If a tool is ground and also placed theoretically correct, it will assuredly do its intended work; if it fail, a closer examination will prove that some error existed which was overlooked. In the case of a tolerably coarse cut a tool may work satisfactorily, which, if drawn back and then reset for a very fine cut may not act as well. In this case I have generally found that it has been badly placed—a shade too high, causing it to rub slightly or a little below the level of centres, or the second edge may not be set sufficiently parallel to the work. No one who has not practised metal-turning would believe how slight a cause will affect the action of a tool. To quote my old friend once more, by way of conclusion, "A hair's breadth in the setting of the tool will make all the difference between a finished surface, so perfect that the least touch of emery would ruin it, and a hitch-in of the following edge, accompanied by the usual results of a spoilt surface to the work, and probably a fracture of the point of your carefully-ground tool." O. J. L.

## THE INTERNATIONAL INVENTIONS EXHIBITION.—X.

### Gas and other Illuminants—Fuel, Furnaces, &c.

ALTHOUGH gas and other illuminants, and fuel, furnaces, &c., are the subjects of two distinct groups, the number of exhibitors is so small in the one section that we will take the two groups together. No very great improvements in the manufacture of gas have been made within the last quarter of a century, but in almost every detail, and especially in connection with the utilisation of the by-products and the methods of consuming the gas, the changes have been considerable—in the case of the by-products amounting to a revolution. The great discovery of the methods of manufacturing aniline dyes from benzol was made in 1856, and the artificial production of alizarine from anthracene, a solid product of the distillation of coal, dates from 1869. Some of the more useful improvements in burners are comparatively old, but the application of the "regenerative" principle is practically new, though it is perhaps senior to the application of the same principle for heating retorts. The exhibits which are connected with the manufacture of gas are not of much interest to the general public, who are concerned rather with its economical consumption than with its production; still there is much to attract the attention of the student even in connection with the drawing and charging of retorts, the working of the hydraulic dip, and certainly in the scheme for withdrawing gas from mines and utilising it for generating steam, &c. That is the Morgan and Shippey process exhibited in large diagrams by the Universal Electric Light and Engineering Co., of King-street, E C., and if the inventors could successfully withdraw the gas from mines, and so prevent explosions, they would undoubtedly achieve an important step in advance, for it seems clear that there is no safety-lamp which will prevent explosions. G. Waller and Co., of Holland-street, S.E., show their patent compensating governor, which is made to act direct on the throttle-valve of the steam-engine and regulate its speed according to the varying flow of gas. A bell works up and down in a vessel holding water; the lower part has a loose float, and a self-compensating water-chamber imparts great steadiness to the governor, which connects to the engine by a rack on the rod projecting from the bell actuating a toothed quadrant connected direct to the throttle-valve. Great steadiness is thus given to the up and down movement of the bell, and there is practically no "hunting" as the gas supply varies. The same firm also exhibit the "absolute" retort valve, which is fixed on the hydraulic main like the ordinary dip pipe—in fact it may be said to be a dip-pipe with a separate valve for the passage of the gas. The dip pipe is so placed that all the tar passes directly down to the hydraulic main, the gas going through the valve; but if the latter has not been opened, it goes through the dip pipe too. The valve is opened by a lever attached to a rod with a hook at its lower end to fasten under a bar by the retort lids, and on releasing that the valve closes at once. These valves are said never to choke with thick tar. Mr. Somerville, of Bankside, S.E., exhibits his patent dip reducer, which removes undue pressure on the retorts, and prevents the entry of furnace gases, as the liquor in the reducer resumes its normal level before the charge is withdrawn, and thus automatically seals the end of the dip pipe. He also shows his patented mouthpieces and self-sealing lids, in which the mouthpiece is cast with its front edge slightly splayed to form an internal conical seating faced up to receive the lid, which is made with a rim in the form of a shallow plug turned on the outside to correspond with its seating. The lid is swung on a hinged cross-bar, to which it is held by a central steel bolt capable of turning freely in a hole in the crossbar, so that the lid can be turned round in the event of dirt impeding its direct action, which is however rare, as the form of the rim clears the seat. Caink's patent automatic pressure-changing gas governor is an apparatus for increasing or diminishing the pressure in the mains according to the supply of gas demanded; it is believed to be the only one which meets the requirements of a district gas governor, and the inventors, Messrs. T. & H. A. Caink, of Sampson-road, Birmingham, claim that it is constructed on the only true principle, as to obtain uniformity of pressure at the point of combustion it is necessary to have a variable pressure at the source of supply. Messrs. A. Wright and Co., of Millbank-street, S.W., show a variety of apparatus, including calorimeters, analytical and testing instruments, Hartley's and other photometers; while Sugg & Co., of Westminster, S.W., have a large collection of their specialities in the shape of burners, and a number of instruments which will attract the attention of gas men. Thus they exhibit an improved Evans's photometer, which does not require a dark room, a patent travelling photometer, the radial photometer designed by Mr. Dibdin, chemist to the Metropolitan Board of Works, which is being employed by the jury for testing the lights at the Exhibition; Sugg's improved jet photometer, in which the pressure required to give a flame of a certain length is an index of the illuminating power. Sugg's patent illuminating power meter is an interesting apparatus, for it is constructed to show the illuminating power by the observation of an index for one minute. The meter being in order, gas is passed through to clear the drum; the burner is then lit, and the flame adjusted to the proper height. When the pointer marks 16 (the nominal value of the gas), the lever is shifted and the gas sent direct to the burner. The clock is now started, and just as the minute hand reaches a division the gas is again sent through the meter for one minute, when it is cut off and the illuminating power read off on the dial. Amongst the exhibits at this stand is Sugg's patent "Cromartie" gas lamp, which is one of the "regenerative" type, in which the gas passes in a nearly horizontal direction from a small hollow-headed burner inverted. The air supply to the upper side of the flame passes between tubes which it serves to keep cool, and the supply to the lower side goes directly to the burner, descending by its own gravity down the sides of the glass. It is stated that the burners consuming 5ft. per hour give a light of 25 candles. These regenerative burners are undoubtedly the chief attraction to the public in this group, and the report of the jury will be awaited with much interest. The Wenham patent gas lamp has been brought out by its inventor a little later in the day than some of the others. Unlike the Siemens lamp, the Wenham is inverted, but is based on the same principle of heating the gas and air by utilising the heat generated by the combustion of the gas. Lamps of several sizes are shown, one burning 18ft. per hour and giving a light tested in the vertical direction of 300 candles, or at an angle of 45°, 200 candles. The maximum illuminating power of the lamp burning 11½ cubic feet is put down at 180 candles; one burning nine cubic feet at 120 candles; and the six cubic feet lamp at 75 candles. These figures, it will be seen, are extraordinary, and there is no reason to doubt them, for it is plainly stated that the No. 1, which burns six cubic feet per hour, has an illuminating power of only 50 candles at an angle of 45°. Still that is very noticeable, and puts the Wenham lamp in the front rank. The lamps can be seen in action all day long at the stand of the Wenham Patent Gas Lamp Co., of 12, Rathbone-place, W., and the advantage of the new lamp can be appreciated by comparison with an ordinary burner consuming six cubic feet per hour. Another lamp of this class is shown by Kirkham, Hersey, and Clark, of Great George-street, S.W., in the shape of F. W. Clark's patent recuperative shadowless ventilating lamp, a title which suggests the remark that the majority of these lamps lend themselves very readily to schemes for ventilation, the heat generated by the combustion of the gas being used as the motive power for extracting foul air from a room. Those who based their recommendation of the electric incandescent lamp on the belief that it was much cooler than gas forgot that the modern gas lamps can also be made to act as ventilating engines, and so compensate for the extra heat they give out. According to a certificate by Mr. F. W. Hartley, the Clark lamp consuming 11·4 cubic feet per hour has an illuminating power equal to 60·33 times that of a standard candle. The Bower "Duplex-regenerative Gas Lamp," exhibited by Mr. Bower, of St. Neot's, Huntingdon, is a combination of the good points in the designs of Messrs. Grimston, Thorp, and Bower, but differs from other lamps of the class in having a lower air tube projecting below the glass cover. This contains an arrangement for varying the air supply so as to adapt it to different qualities of gas. According to Dr. Wallace, of Glasgow, a No. 2 Bower lamp, consuming 12·16 cubic feet per hour, yields an illuminating power of 109·62 candles when tested horizontally, elevation of course increasing the amount of light, a remark which suggests the advisability of taking all statements as to the illuminating power of any given lamp with caution, for no proper comparison can be made unless they are all tested in exactly the same manner. Next to the gas lamps the public will be mainly interested in those constructed to burn mineral oils; but before referring to them we must mention that the Albo-Carbon Light Company, of Horseferry-road, S.W., have an excellent exhibit of their appliances for enriching gas with a hydrocarbon. Kynoch and Co., of 199, Piccadilly, W., exhibit Martin's lamp, which has two semicircular wicks combining to give an annular ring of light, while Browne and Co., of 186, Paccadilly, exhibit the "Mitrailleuse" lamp, which has 16 small round wicks all raised or lowered by the one key. It is, in fact, a sort of Argand burner with wicks, the centre portion being used to distribute the air direct to the small flames, thus insuring perfect combustion and the maximum amount of light. The lamp is said to need trimming only once a week. Messrs. Defries, of Houndsditch, exhibit their safety lamp (Sepulchre's patent), which has received the high commendation of Mr. Boverton Redwood, and is so constructed that neither ignition of the vapour nor overflow of the oil in the event of an upset can occur. It is said that this lamp cannot possibly explode, and that, in the event of being accidentally overturned, it is automatically extinguished, while it will burn such perfectly safe oils as those having a firing-test of 300° Fahr. Mr. Daniell, of Linslade, Bedfordshire, exhibits his patent oil lamp chandelier, in which the wicks are laid in the tubular arms, and Flatau and Turner, of Mincing-lane, E.C., show their railway-roof lamp in action. This lamp burns mineral oil without the assistance of wicks. Jones and Willis, 43, Great Russell-street, exhibit a collection of ornamental designs for lamps, and their well-known triple-wick lamps. Amongst the other illuminants, attention must be drawn to Webb's wickless, non-guttering candle, exhibited by Gray and Son, 115, Leadenhall-street. This is an ingenious device, in which a disc of gauze, carrying a little wick of asbestos, is placed on the top of a cylinder (or candle) of wax, &c., and held in position by a sleeve, which slides down the candle as the substance is consumed. The sleeve prevents the disc slipping off the top, and the "wick," with the sleeve, sinks down as the candle is consumed. As there is no "pool" of liquid hydrocarbon near the "wick," guttering or spilling of the melted wax or tallow is prevented. Messrs. Garratt and Fowler, of Leipsic-road, S.E., exhibit their plumbers', gas-fitters', and painters' lamps, which contain a supply of cotton, on to which the spirit is poured, and the vapour of which rises as it is required. The air is supplied by a mouth blowpipe, and by means of a little tap the outlet of the air can be shifted so as to give a small jet or a broad flare. These lamps can be used in any position, and will enable the plumber to wipe a large joint in all sorts of out-of-the-way places. As there is no reservoir of spirit, they are perfectly safe. The same exhibitors also have an improved union which can be screwed up tight without running a risk of twisting the pipes. It is in reality an octagon fitting, which is made tight by screwing up a sleeve nut. In connection with gas meters we notice several attempts to design a "readable" index. Mr. Grey, Whitehead's-grove, Chelsea, adopts the form of a ring on the index finger, which shows the figure that is to be read; but the best of all the designs is, we think, the clock dial of Messrs. Foxall, Llewellin, Jones, and Co., of Newport, Mon. In this the index resembles a clock dial, with the usual two hands, but only 10 figures. The long hand reads thousands, and the short hand tens of thousands of cubic feet—an arrangement which can scarcely puzzle anyone. Their testing index is also an improvement, for, instead of a little hand liable to fall, they use a disc which revolves behind a vertical wire, and which, being equally balanced, indicates to any required degree of accuracy. The same firm also exhibit improvements in dry and wet meters. The dry meter, for instance, has the bellows supported both vertically and horizontally, so that it must always retain its full capacity, and must expand and close symmetrically. The wet meter has an improved valve, which is proof against any pressure, and can close the outlet only when the water is too low. Amongst pressure governors for use by consumers, Stott's (174, Fleet-street) is shown in various forms, some of them being entirely new devices for use with the regenerative burners, to which they have been applied in some cases in the Exhibition. It consists of a dome, or ring, of iron working in a trough containing mercury, and weighted to a certain pressure. As the pressure of the gas increases the dome lifts, and closes, or rather decreases the area of, the orifice forming the inlet of the gas by means of a conical valve.

Tice's gas regulator is shown by its patentee, W. Tice, Thornilee, Sutton, the special feature being the absence of any liquid, a flexible diaphragm causing a conical valve to be drawn into the inlet orifice as the pressure increases. Carter and Lees, Oldham, exhibit a pressure regulator with the dome and the mercury trough; but having patent equilibrium valves, and an arrangement by which the weight on the valve is increased automatically as more lights are brought into use. That is accomplished by means of a weight pivoted at one end, and pressing on the valve spindle by means of an arm. In the upright position the weight has little or no effect on the valves; but tends to force them wider open as the pressure decreases. Bromhead's dry gas regulators, which have been used for some time at St. Paul's Cathedral, and at several noted houses and clubs, are shown by Bromhead and Co., of 28, Paternoster-row. There are one or two self-lighting arrangements for gas burners, which, however, depend on the keeping of a small jet constantly burning, and in draughty places that is liable to be blown out. Kinnear's patent, 91, Finsbury-pavement, is a self-lighting burner with automatic governor, which is said to save 25 per cent of gas. J. Freeston and G. Kyle, of Geddington, Kettering, exhibit an ingenious self-acting regulating machine for extinguishing and re-lighting gas lamps in the streets. The motive power is derived from the air entering the lamp, which drives a small fan. The fan by gearing works a wheel carrying a number of pins, which, set according to the season of the year, turn the tap of the gas burner off and on, the gas being lit by a small jet constantly burning. The gearing requires setting about three times in the year, but as lamps must of necessity be cleaned occasionally, there is no extra labour involved. Messrs. Kirkham, Hersey, and Clark also exhibit Clark's gas-making apparatus, which is found very useful in country places. The mineral oil or hydrocarbon liquid flows into a copper retort as it is required, and is there subjected to a destructive distillation. The products being mixed with warm air, a permanent gas of high illuminating power and of uniform quality is formed. The apparatus is self-contained, the heat requisite being generated by the machine itself. Amongst the exhibits in this group we must not omit to mention Mr. Newman's art metalwork in connection with gas fittings, and his wrought-iron candlesticks of coiled rod, by means of which the candle can be raised as it burns down.

In the Fuel and Furnace Group Mr. F. Siemens shows a large-size model of the improved forms of regenerative furnace and gas producer, and also a few samples of his tempered glass bottles, millstones, and sleepers especially adapted for electrical railways. Mr. Fletcher, of Warrington, has a large collection of his famous cooking and heating apparatus in which gas is utilised, including laboratory furnaces and his coffee roaster, which is worth notice by those who like to have coffee in perfection. Mr. C. Kingsford, of the Lea Chemical Works, Hackney-wick, shows a large model of his system of combining a steam-boiler plant with coke ovens, so as to utilise the waste heat of the latter in firing the boilers. Captain A. S. Tomkins, of the Victoria Rifles, shows his field or camp stoves for cooking, which will be found very useful and suggestive to all who desire to camp out. Several of the exhibits of ranges, kitcheners, &c., are apparently remanets from the Health Exhibition; but are sure to attract the attention of ladies, especially the self-fitting stoves, like the "Gem" shown by Brown and Green, of Finsbury-pavement. The patent safety gas-stove, constructed on Somerville and Webber's patent, by the Patent Gas-stove Company, Hatcham-park-road, S.E., will also interest many, as it depends on radiant heat from illuminating burners, instead of Bunsens, and is, therefore, quite free from any tendency to alarm to the cook by flying back. The oven lining is of tinned copper, and can be removed for cleaning, while the waste or escaping heat is used for warming water. This stove has, we believe, never before been exhibited, and it certainly merits careful attention. We have, however, said sufficient to prove that the groups devoted to gas, &c., are not the least interesting portions of the Exhibition.

## ON SOME MATTERS IN THE THEORY OF MIRRORS.—II.

By W. BRADBURY.

§ 4. TO apply the rule to a Cassegrain telescope.

In this case parallel rays falling on the great mirror are converged by it on a small convex mirror, which brings them to a focus at or behind the vertex of the great mirror. Let Fig. 3 represent this arrangement, A being the final focus, B the vertex of the great speculum, and C its focal point, D the vertex of the small mirror, and E its focal point. Thus, in this case the rays fall on the small reflector before completing their convergence, whereas in the Gregorian they encounter it after passing the focus. Let $AB = a$, $BC = F$, $DE = f$, $AD = v$, $DC = u$. Therefore $BD = F - u$, and $AD = v = a + F - u$. This being a case of the reflection of con-

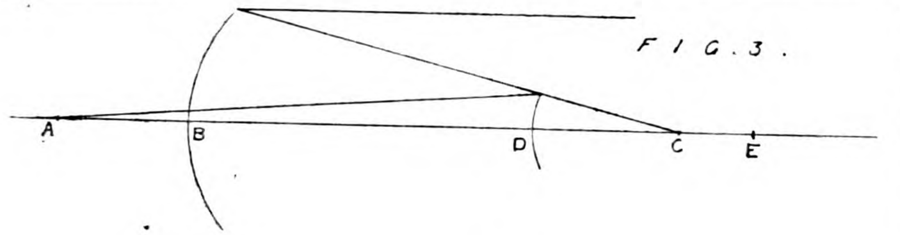

FIG. 3.

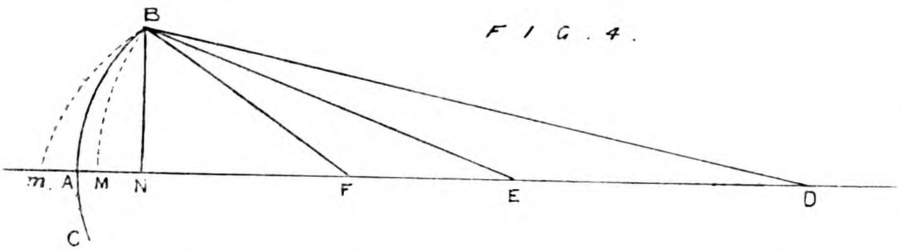

FIG. 4.

verging rays, falls under eqn. (8), which may be put in the form—

$$\frac{1}{u} - \frac{1}{v} = \frac{1}{u} - \frac{1}{a + F - u} = \frac{1}{f} \quad \ldots\ldots\ldots(16)$$

Or, as a quadratic eqn.—

$$u^2 - u\,(F + a + 2f) = -f\,(a + F) \quad \ldots\ldots(17)$$

As before, assume for brevity that $(F + a) = m$, then—

$$u^2 - u\,(m + 2f) = -mf.$$

The solution of which gives—

$$u = \frac{m + 2f \pm \sqrt{m^2 + 4f^2}}{2}$$

Now $m = F + a$ and $BD = F - u$, which substitutions give

$$BD = F - f + \tfrac{1}{2}\left\{\sqrt{(F+a)^2 + 4f^2} - (F + a)\right\} \ldots(18)$$

Also CE, the difference between the principal foci of the mirrors, is

$$CE = f - u = \tfrac{1}{2}\left\{\sqrt{(F + a)^2 + 4f^2} - (F + a)\right\} (19)$$

Hence it will be seen that the distance apart of the mirrors is somewhat greater than the difference of their foci.

As a particular case, assume that $a = 0$, then we have

$$BD = (F - f) + \tfrac{1}{2}\left\{\sqrt{F^2 + 4f^2} - F\right\}$$

$$CE = \tfrac{1}{2}\left\{\sqrt{F^2 + 4f^2} - F\right\}$$

and if the focal ratio $f/F$ be represented by $r$, these become

$$BD = F\left\{1 + r + \tfrac{1}{2}\left(\sqrt{1 + 4r^2} - 1\right)\right\} \ldots.(20)$$

$$CE = \frac{F}{2}\left(\sqrt{1 + 4r^2} - 1\right) \quad \ldots\ldots\ldots\ (21)$$

When the quantity under the vinculum is developed in a series, and the first three terms used, we find—

$$BD = F\,(1 - r + r^2 - r^4) \ldots\ldots\ldots\ldots\ldots(22)$$
$$CE = F\,(r^2 - r^4) = Fr^2\,(1 - r^2) \ldots\ldots\ldots(23)$$

To show the amount of error given by the last pair of equations, let us calculate several values for different ratios by both pairs of equations.

$$\begin{array}{lll} & \text{By (20) and (21).} & \text{By (22 and 23).} \\ r = \frac{1}{3} \ldots & BD = F \times \cdot 7675 \ldots & F \times \cdot 7654 \\ & CE = F \times \cdot 1008 \ldots & F \times \cdot 0987 \\ r = \frac{1}{4} \ldots & BD = F \times \cdot 809 \ldots & F \times \cdot 808 \\ & CE = F \times \cdot 059 \ldots & F \times \cdot 058 \\ r = \frac{1}{5} \ldots & BD = F \times \cdot 8385 \ldots & F \times \cdot 8384 \\ & CE = F \times \cdot 0385 \ldots & F \times \cdot 0385 \end{array}$$

A geometrical relation amongst the focal distances may be found as follows, though it is not of much practical utility. In equation (19) let CE be represented by $x$, then we find—

$$x\,(F + a + x) = f^2$$

Substituting from Fig. 3 the geometrical for the algebraical quantities in this equation, it gives (since $CE = x$, $AE = F + a + x$, $DE = f$).

$$CE \times AE = DE^2$$

Or, as a proportion—

$$AE : DE :: DE : CE.$$

This holds true for any position of the point A, so that when A and B fall together—

$$BE : DE :: DE : CE.$$

The above geometrical relation is applicable to the Gregorian as well as the Cassegrain form.

Having now given the chief formulas which show the relations among the foci, it is necessary to proceed to the more complex problem of finding the aberration of a spherical reflector. In this question we shall follow entirely the analytical method of Coddington.

§ 5. To compute the spheric aberration of a mirror.

First, for a concave mirror.

In § 1 we had the eqn. D.

$$\frac{FB}{FE} = \frac{DB}{DE}.$$

and it was shown that when A and B are so near together that distances measured from either are practically alike, we obtained rules which furnished the means of finding the positions of the focal points for the so-called central rays; but obviously the higher the point B rises on the curve away from A, the greater is the difference in the length of lines measured from A and B; and consequently the greater is the error in the formula. Hence it becomes necessary to use, not the central values of FB and DB, but others which take into account the distance of A from B. In Fig. 4 the various points correspond to those in Fig. 1: from B, drop the line BN square apon AD. BN is called the semi-aperture of the mirror, and is generally represented by $y$. Next, from D as centre with BD as radius, draw the arc BM; and from F, with radius BF, draw B $m$. Then, of course, DM and F$m$ are the exact lengths of DB and FB, and AM and A$m$ show their difference from the corresponding central lines AD and AF. But $AF = v$, $AE = r$, $AD = u$, and the equation (1), when inverted, may be put—

$$\frac{r - v}{v + Am} = \frac{u - r}{u - AM} \ldots\ldots\ldots\ldots\ldots\ (24)$$

and the next step is to find the values A$m$, AM.

By the property of the circle $y^2 = 2rx - x^2$, where $y = BN$, $r = AE$ and $x = AN$. But since $x$ is very small compared with $r$, we may neglect its square, and say that AN or $x = y^2 \div 2r$. And for the circular arc, struck from D, we may put $MN = y^2 \div 2u$; and for that from F, $mN = y^2 \div 2v$. From these values we readily find A$m$, AM, and eventually

$$v + Am = v + \left(\frac{1}{v} - \frac{1}{r}\right)\frac{y^2}{2}$$

$$u - AM = u - \left(\frac{1}{r} - \frac{1}{u}\right)\frac{y^2}{2}$$

The second quantity is very small compared with the first, and the reciprocals may be put in a serial form, rejecting all terms after the second. This gives—

$$\frac{1}{v + Am} = \frac{1}{v}\left\{1 - \frac{1}{v}\left(\frac{1}{v} - \frac{1}{r}\right)\frac{y^2}{2}\right\}.$$

$$\frac{1}{u - AM} = \frac{1}{u}\left\{1 + \frac{1}{u}\left(\frac{1}{r} - \frac{1}{u}\right)\frac{y^2}{2}\right\}.$$

By these values being substituted in (24) and the equation then divided by $r$, we have—

$$\frac{1}{v} - \frac{1}{r} - \frac{1}{2v}\left(\frac{1}{v} - \frac{1}{r}\right)^2 . y^2 = \frac{1}{r} - \frac{1}{u} + \frac{1}{2u}\left(\frac{1}{r} - \frac{1}{u}\right)^2 y^2 \ldots\ldots\ldots (25)$$

Now, the first part of each side is in reality our first approximate focal formula, so that the coefficient of $y^2$ embodies equal terms; and if we write $\frac{2}{r}$ for $\left(\frac{1}{u} + \frac{1}{v}\right)$ we get

$$\frac{1}{v} = \frac{2}{r} - \frac{1}{u} + \frac{1}{r}\left(\frac{1}{r} - \frac{1}{u}\right)^2 y^2.$$

or, if $f$ is the principal focal length—

$$\frac{1}{v} = \frac{1}{f} - \frac{1}{u} + \frac{1}{2f}\left(\frac{1}{2f} - \frac{1}{u}\right)^2 y^2 \ldots\ldots (26)$$

---

# THE AMATEUR WORKSHOP.—IX.

## Planing Machines—Vertical Slides.

THERE is not much variation in the types upon which these are constructed. In the larger machines the castings are hollow throughout, on the boxed principle, as in the illustration (Fig. 2) on p. 444 of the last volume, and the elevating screws are inclosed in the hollows of the castings. These frames are all made roughly triangular in outline, in order to resist the reaction of the cutting tool. In the larger machines they rest directly upon the ground foundation as in the Fig. 2 referred to above, and the bolts which connect them to the bed sides simply retain the parts in place, while in machines of medium and of small size they are sustained either directly against the bed or upon brackets cast with it as in our own particular case. In some instances the bearing faces are prolonged downwards to carry an extra tool box by the side of the table, and additional gear is provided for moving it. The bearing faces require to be planed accurately to receive the cross slide, and they are kept rigid laterally by the bed below, and by a cross bar near the top.

The slide here figured is a plain plated casting, stiffened with flanges round the edges. It would involve slightly less work if the back, instead of being curved, were made straight, though the curve has a better appearance. In the Figs. 88, 89, 90, the lug A carries the end of the elevating screw, which is therefore placed without the frame, and the plate B is brought to one side of the centre, both to give flange room at the bottom for the holding-down bolts, and to allow sufficient width for the heads of the tightening bolts to slide freely—the bolts passing from the cross slide, through the slots C, to the back of the $2\frac{1}{16}$in. thickness. A T-headed recess for the bolt heads (Fig. 91) would answer equally well, but the inner bearing faces of the recess should be planed in that case, and this would be more troublesome than the filing of a clear slot. The facing D is for the end of the cross bar, and the narrow strip E is for the purpose of affording additional guidance to the cross slide, besides that provided by the screws and nuts.

In the pattern, the plate will be framed together in a similar fashion to the standard (p. 468 of the last volume), four pieces, *a*, *b*, *c*, *d*, being required, and corner pieces for the hollow radii being glued in. An ⅛in. allowance will be made upon the face for fitting; but it is not necessary to carry this right down to the bottom flange, but only so far as the lower lugs of the cross slide will come when at their lowest position. Hence the bottom flange will be 1ft. 1in. long in the pattern; but 3in. above the foot the front face will be increased an ⅛in. in thickness, and carried thus right to the top.

Upon the plate when cut to shape and cleaned off will be screwed the remaining work. The bottom flange F will measure 1ft. 1in. by 2¼in. by ¾in., and its bottom face will be square with the plate, a trifle of taper being put upon its inner face only. The front or slide portion G will be made up by one piece measuring 2ft. 0⅜in. by 2¼in. by 2⅜in., and fastened to the plate. On the back or inner side of this strip a thin facing 2ft. 0⅜in. by 1⅜in. by ⅜in. should be tacked, to afford a narrow and true bearing surface for the heads of the tightening bolts, and thus prevent the frequent hitch or diagonal bite which occurs against an uneven surface.

The plate will be strengthened and stiffened with ribs, *e*, *e*, *e*, 1¾in. deep, and cut to their respective curves from a piece of stuff planed to that thickness. The ribs around the inner curves will be jointed as shown by the dotted lines, Fig. 88, in order to avoid shortness of grain. Glue must not be used in any except the half-joints of the plate itself, because all the parts will have to be reversed, for right and left-handed castings respectively.

The print for carrying the slot core C will be prepared to 1ft. 10in. by 1¼in. by ¾in. (it is made thus wide purposely to afford sufficient

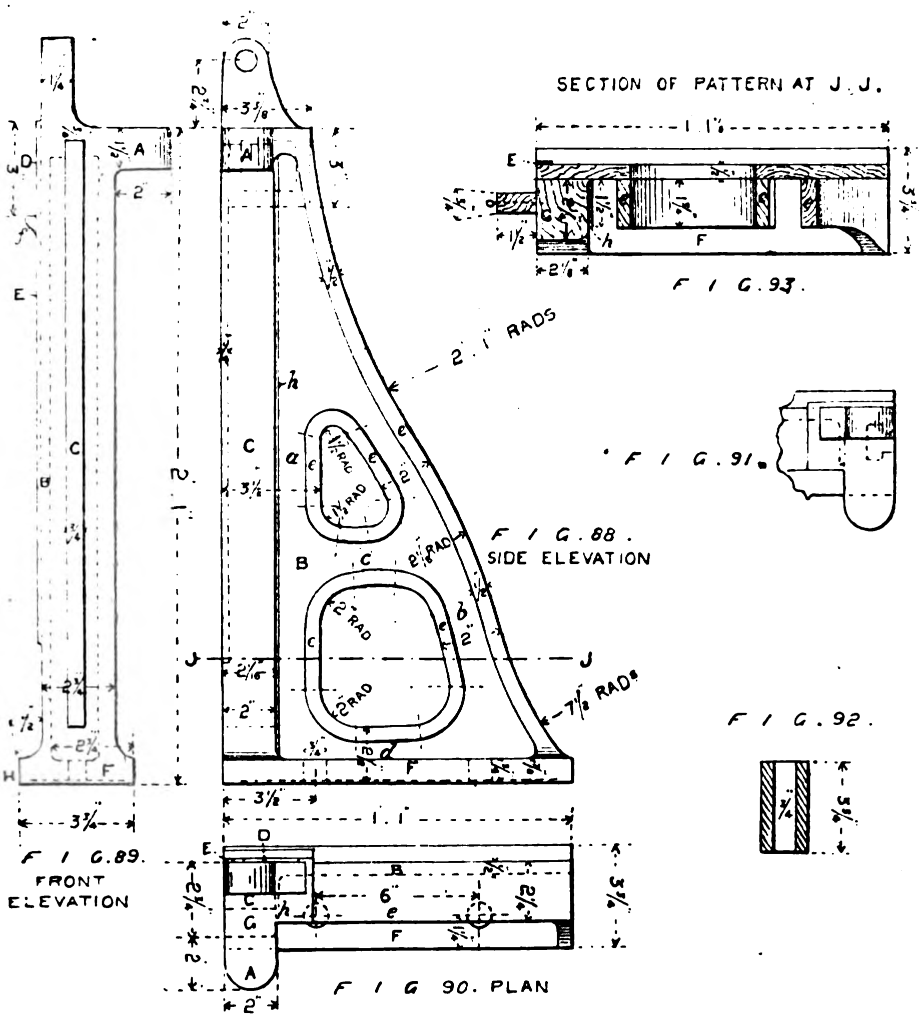

FIG. 89. FRONT ELEVATION

FIG. 88. SIDE ELEVATION

FIG. 93.

FIG. 91.

FIG. 92.

FIG. 90. PLAN

support to the core without other assistance), and a couple of shavings off each side will give enough taper in this case. If much taper were given, and the moulder did not file the corresponding taper in the core symmetrically, the slot would be out of parallel in the casting. The print is skewered on, and a core box of the plain section (Fig. 92) is made, equal in depth to that of the print and casting combined, and 1ft. 10in. long. The lug A, which sustains the bevel wheel and the elevating screw, made to the size and shape of Figs. 89 and 90, and 1½in. thick, will be fastened on. The facing, D, on the back will consist of four chipping strips of ½in. by ⅜in. section, and fastened on in rectangular form 3in. square—one side of the rectangle being flush with the top; another, ⅜in., from the front edge. A joggle *f*, Figs. 88 and 90, 3in. long, will be fastened on 3in. below the top to form a steady bearing for the cross bar. On the back of the plate a strip, H, will be wanted, 1ft. 1in. by ¾in. by ⅜in. to complete the width of the foot; and on the same side of the plate, and running up its inner edge, the facing strip, E, 1ft. 10in. by ⅝in. by ⅛in. will be fastened. A chipping strip of a ¾in. by ¼in. section will be put around the foot, the lower strip only being skewered on. Bolt holes should not be cast, but drilled in. Fig. 93 shows a section of the pattern cut through J J, to enable the reader to understand clearly the descriptions here given.

In reference to the provision for carrying the wheels for the elevating screws, there are two or three methods open to our choice, the adoption of either of which would involve modifications in our patterns. In Fig. 1, on p. 444 of the last volume, I illustrated the very common method of carrying the wheels by means of hood-shaped bearings resting upon the top of the horizontal wheels, and kept in place on the spindle by a small check pin. But a simpler method would be that shown in Figs. 88, 89, 90, where a couple of lugs cast upon the vertical slides take the bearing of the cross spindle, and as this gives rather less trouble in the making than the independent wrought-iron bearings of Fig. 1, and is very commonly employed in small machines, I have drawn that attached to the pattern of the slide, and should advise its adoption. In large machines bearings of either kind are employed. Where the cast bearings are used, they are frequently cast in a piece with the stretcher or cross-bar. Or the bearings of each wheel in the pair are taken on a single curved bracket, which is bolted to the top of the vertical slide. Of these methods the attachment shown in Fig. 88 is most suitable for our machine, and in that case we simply have to make a lug, as drawn, and fasten it on. If the independent bearings are chosen, the pattern is already complete without the lug.

Two castings are required, one right, the other left-handed; so after the pattern has been moulded for the first, the pattern will be reversed by transferring all the parts from each side of the plate to the sides opposite. The two castings will weigh 136lb., and should cost about 12s. per cwt.

The fitting of these slides will be a comparatively easy affair after the table and bed, the most important part being the front face. The instructions given on pp. 468 and 554 of Vol. XL., relative to chipping and filing, need not be repeated again, since they will apply equally well in this instance. The faces should be filed first, at exact right angles, with the edges of the feet; and true lineally, and the chipping strips on the feet will be filed afterwards perfectly square with the bearing faces in front, and with the plate at the sides. The necessity for this carefulness will be apparent when we come to try the slides in their places on the bracketings of the bed, and to test them relatively to each other and to the bed with straightedge, checked across their faces, and with square or level in relation to the faces of the bed. Both slides, when stood in place, should show faces perfectly parallel with one another, and the bed being adjusted with spirit level, the slide faces should, when tried with the same instrument, show perpendicular. Some little adjustment will sure to be necessary before these results are attained, and this can be done easily on the chipping strips. Lastly, the holes will be marked off from the brackets in Fig. 38, p. 554 of the Vol. XL., and drilled to ¾in. in diameter.

The facings for the stretcher bar, and the guide strips for the cross-slide, have yet to be filed, and the holes have to be drilled for the spindle and the screw. At this stage, therefore, we had better let this work remain until after the cross-slide and stretcher, with the wheels and their spindles, are made, the preparation and fitting up of which will furnish the subject-matter of our next article.

## MAKING LANTERN SLIDES.*

I REGARD the successful development of lantern slides as one of the most difficult and delicate things that I have as yet met with. Many subjects which make excellent silver prints fail to make good lantern slides. The formula which I use is slightly modified from that recommended by Mr. Carbutt, and I prefer to use his slow gelantino-albumen plates.

No. 1.

| | |
|---|---|
| Water | 32 ounces |
| Sulphate of iron | 8 ounces |
| After filtering, add | |
| Sulphuric acid | 40 minims |

No. 2.

| | |
|---|---|
| Water | 32 ounces |
| Citric acid | 60 grains |
| After dissolving above, add | |
| Neutral oxalate potash | 8 ounces |

If the solution does not turn blue litmus paper faintly red, a trifle more citric acid is added, and when this is dissolved, add

| | |
|---|---|
| Citric acid | 300 grains |

Mr. Carbutt advises the following proportions for the developer:

| | |
|---|---|
| Oxalate of potash solution | 5 ounces |
| Iron solution | 1 ounce |
| Bromide of potassium | 6 grains. |

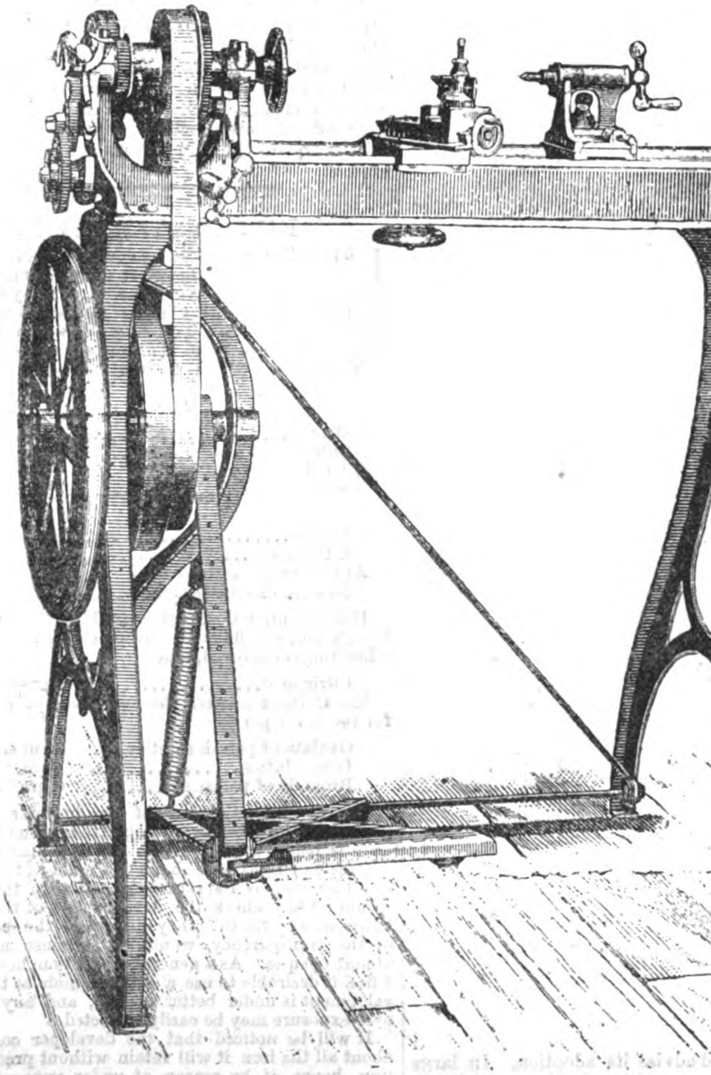
In respect to the use of the bromide, I am governed altogether by the negative from which the slide is being made. If the negative has strong contrasts of light and shade I should not employ any bromide, as its retarding action in this case would unduly check the development of the high lights, and by the time they did appear, the shadows of the transparency would be so dense as to be almost opaque. As a general precaution, however, I find it desirable to use a little bromide as the development is under better control, and any slight over exposure may be easily corrected.

It will be noticed that the developer contains about all the iron it will retain without precipitation, hence, if by reason of under exposure the image fails to develop fully, nothing can be done to force the development, for if more iron is added a precipitate will be formed. On the other hand, if a long exposure is given and the developer containing a bromide is poured upon the plate, there is some chance of saving the transparency in case the bromide checks the development too much, by pouring it off and flowing with a fresh developer containing no bromide. When the developer is used full strength as given, it is of vital importance to have the exposure exactly right, and this is very easily done when the copying camera is in the same place and a uniform light employed, either from the sun or a northern sky. I find in reducing a 5 × 8 negative to 3¼ × 4, having the copying camera containing the negative placed within 6in. of the window, and the latter protected by a piece of ground glass or white tissue paper, the sun's rays shining direct, or nearly so, upon it, an exposure of from five to seven seconds is sufficient for negatives of ordinary density. For a very thin negative, I have reduced the time to cap on and off. I prefer this latter exposure for negatives of such subjects as rocks, white stone buildings, steamboats, sailing vessels, and rough water and marine views. In such cases I use the developer at its full strength, as I notice it yields what are called "black and white" tones, but which are actually more black and blue or black and very dark purple, such as is often seen in an ordinary silver print. For such objects as landscapes containing considerable foliage and grass, brown stone buildings, or those composed of the yellowish brick much used at the present time, I prefer a dilute developer, as I think it yields tones more in accordance with the subject. The exposure should be trebled, and the strength of the developer reduced one-half, putting in one grain of bromide to two ounces of solution, and picking out the plate when the development has proceeded far enough.

By commencing the development with a weak solution there is little need of ever losing a plate. My plan of proceeding is as follows: Suppose we have two ounces of developer just half the normal strength in the tray, and in a graduate near by an ounce of the same full strength, now this latter solution can be added, a little at a time, if necessary, to bring out the picture without danger of causing

---

* By A. B. Benjamin. A paper read before the Societ of Amateur Photographers of New York.



any immediate chemical change in the developer. I do not advocate using a developer that has been mixed over thirty minutes, as beyond that time the yellow precipitate begins to form, and though the developer appears to remain clear, there is a sprinkling of golden sand deposited on the surface of the plates, which, while it can be easily removed by a constant and rather violent agitation of the tray, is a movement that is really needless so long as the plate is well covered. When a negative to be reduced is thick on one end and thin on the other, the thin portion can often be shaded with success. I have even thrown a handkerchief over the thin end, and thereby obtained a more even illumination. Until some better light is provided, it will be necessary to make a double set of slides for home exhibitions, one suited for oil and the other for the limelight. I have some subjects that I cannot develop thin enough for oil, and retain any pluck, yet if the development is continued, the transparency becomes practically worthless. I employ two cameras facing each other, in one the negative to be reduced is placed in a kit in the space occupied by the plate-holder, and the lens front is removed. The lens of the copying is inserted in this aperture, and the space between the two cameras covered by a black cloth; this plan I find works very successfully, and avoids the necessity of using a copying camera. In focussing I employ a magnifying glass. The making of lantern slides is to me extremely fascinating, and if I have imparted any information which can be utilised by others, I shall feel that my experience has not been in vain.

## THE PROVIDENCE SCREW-CUTTING LATHE.

THIS lathe possesses several important features of construction, some of which are represented by detail views. It is designed for use on electrical work, sewing machines, or other light work, and is a very convenient tool for amateurs. It will turn 18in. long, 4½in. diameter, and swing 8in. over the bed. The gearing furnished enables screws to be cut from five to the inch up to very fine pitches. It has a hollow steel spindle to take rods up to $\frac{5}{16}$in. diameter. The spindle bearings are straight, with adjustment for wear. The centres are fitted to Morse taper. The tailstock has set-over for turning tapers, and the slide rest swivels on the carriage.

Fig. 1 represents some of the features of this lathe. The gear teeth are represented by heavy black lines. A is the spindle gear, shown disconnected from the right and left gears, B and C. It will be observed that if the back gear is disconnected there will be no gears running in connection with the spindle, so it can be run at high speed without noise. The lever, E, connects either the right gear, B, or the left gear, C, with the spindle gear, thus driving the screw, S, right or left, as desired; F is the fixed stud, and G is the intermediate stud. On coarser threads the gears on the stud, G, may act as intermediate; on fine threads it may be compounded, as shown; this gives a very wide range of threads. An index plate accompanying each lathe gives 29 threads, but many others may be obtained, or gears may be made for special threads. This system of gearing is very direct and simple. The screw-cutting train of gears are all 20 diametral pitch, and the back gears 16 pitch. By means of a novel motion the spindle may be instantly reversed at any point and run backwards without stopping the lathe. This is entirely separate from the ordinary right and left motion, and completely reverses the spindle and screw-cutting gearing, running the carriage back while the lathe is going at full speed forward. This is accomplished by means of an addition to the usual back gearing. On the same shaft with the usual large back gear, H, is the gear, I, of the same diameter; these gears are connected by means of the gears, J and K, thus the motion of the gear, I, is exactly the reverse of the gear, H. Now, as these gears (H and I) are on the back gear shaft, and revolving loosely in opposite directions, and as the spindles are driven through these gears, it only remains to connect the back gear shaft with either the regular back gear, H, or the oppositely running gear, I, to produce a forward or backward motion of the spindle. This is done by means of a clutch operated by the lever, L. Then, if, while the belt, M, and pulley, N, are running forward, the lever, L, is pressed towards the pulley, N, the gear, I, will be connected with the shaft, and the spindle will run backward, carrying with it the screw-cutting gearing, and running back the carriage to start another cut. It will be noticed that the train of gearing from the spindle to the screw remains unbroken, hence the operation of the reverse gearing is precisely the same as that of a countershaft with straight and cross belt.

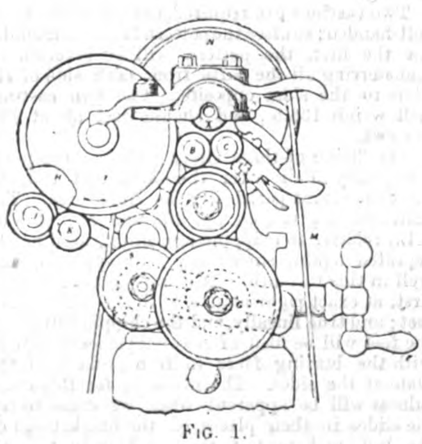


FIG. 1.

Fig. 2 is a view of the carriage and section of one of these foot lathes, showing the bed in section.

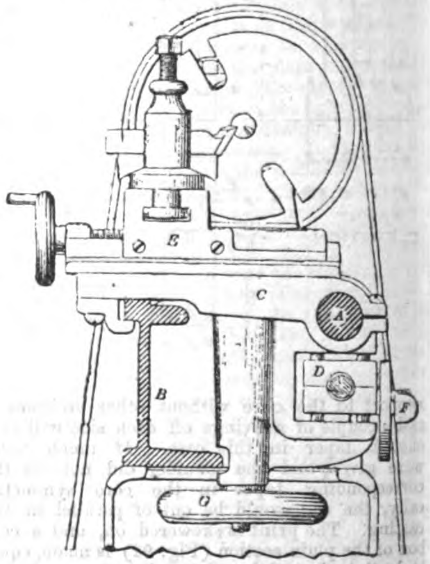

FIG. 2.

The front side of the bed consists of a single casting 3⅜in. deep, as shown at B. In place of planed V's to guide the carriage, C, a compressed steel bar, A, is used at the back, as shown; the front being gibbed to the bed, B. The bed is deep, and being directly under the tool-post, receives all the pressure from the same, the bar acting only as a guide. The bar and bed being placed well apart, form a broad and firm support for the carriage. The screw, D, is placed close to the guide bar, A, thus avoiding any cramping of the carriage. By means of the cam, F, the half nut may be separated and the carriage detached from the screw, and moved by hand to any part of the bed. The slide-rest, E, is secured to the carriage by a bolt, which is tightened by the wheel, G. It may be set at any angle for turning or boring tapers, or instantly removed and a T-rest holder, or other device, substituted. The slide-rest and carriage are milled true on their edges, so that the slide-rest may be easily set square with the guide bar. The top part of the slide-rest extends back so as to cover the wearing parts and protect them from chips and dirt; it also acts as a support for the tool. The point of the tool may be raised or lowered by means of the convex washer and concave shoe. The slide is gibbed, to provide for any adjustment it may need.

The foot power is shown in Fig. 3. On the lever pulley shaft is a clutch, C, which, when the treadle, D, is pressed, engages with and gives motion to the pulley. On the stopping or returning of the treadle, the pulley continues its rotation, so the strokes may be long or short, quick or slow, at the will of the operator. The spring, E, raises and balances the treadle. The cone, B, has two steps, 2⅛in. and 5in. diameter. The lower cone pulley has steps, 12in and 9¾in. diameter. An additional balance wheel, F, is provided. This foot power is all ready to start from any position, and no power is wasted on it. With back gears a speed of 25 revolutions may be kept up; without back gears the speed may be varied from 120 to 3,000 revolutions. It always starts in the right direction. The

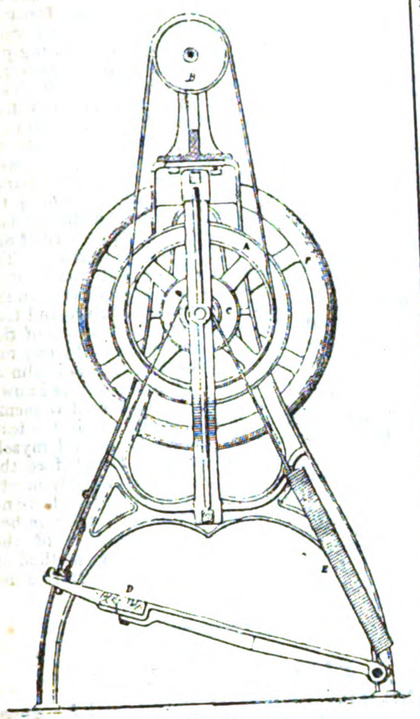

FIG. 3.

foot can remain at rest on the treadle while the machine continues to run, thus avoiding the motion necessary to crank motions, even when power is not needed. This last feature is one that will be appreciated in delicate operations. The lathe is made by the Narragansett Machine Company, Providence, R.I.—*American Machinist.*

## THE CAMPHOR BAROMETER OR "STORM GLASS."*

IT was discovered by our ancestors that the height of the undissolved camphor in a camphor bottle was different in different states of the weather; and it became quite customary to keep a camphor bottle in sight, in order to anticipate the change in the weather, it being thought that an increase in the height of the camphor indicated approaching rain or wind. The inventive genius of our age could not allow the instrument to remain in this crude form.† The camphor‡ and alcohol were put into long glass tubes hermetically sealed at the top, and adjusted in a frame with a thermometer attached. The side of the frame next the tube was divided into three divisions. On the bottom one was marked the word "Fair," on the middle one "Change," and on the top one "Storm." A note accompanying the instrument stated that the weather was indicated by the word in the division with which the top of the chemical substance corresponded. It also stated that the direction of the wind was shown by the substance being a little higher on the opposite side from which the wind came. These were manufactured and sold all over our country under the name of "Storm Glasses," or "Chemical Barometers." One firm, I suppose in order to increase the sales, adopted the name of "Signal Service Barometer;" and I have met a number of people in possession of these instruments who really thought they had one of the genuine barometers which the Signal Service used in its predictions.

The fact that the manufacturers have hermetically sealed the top of the tubes fortunately assists in an investigation of the cause of the instrument's action, for it is evident at once that the contents of an impermeable, air-tight vessel of glass can neither be affected by variations in the atmospheric pressure nor moisture. That light is not the cause of its action can be easily shown, for the chemical substance varies in height in the dark just as it does in the light. Neither can its changes be due to the action of the electricity of the air, for the changes of the tube take place the same in a protected shelter as they do in the open air, and the electric potential inside of a shelter is always zero.* We turn to changes of temperature for the cause of its variations, and find a most satisfactory explanation of its action. If it is winter, one can easily convince himself of this by taking the instrument into a warm room. If now the instrument be hung out of doors, the precipitate will in a little while increase greatly in quantity, and if the difference of temperature is considerable, the alcohol in the tube will be filled from top to bottom. I have a tube on which I have divided the length from the top of the alcohol down to the bottom into ten parts, and these again into ten parts, so that I can read the height of the precipitate at any time in hundredths of the greatest height to which it is possible for it to extend. March 24, I found the instrument hanging in my room read 21 on the scale, temperature inside of room 73°, outside 27°. I placed the instrument outside, and in two minutes little stars began to form at the side and to move down toward the bottom and up to the top again in the centre of the tube. These continued to increase in size, and in five minutes the alcohol was about one-quarter full of them. As these increased and the circulation of the liquid became slower, they began to accumulate at the bottom and somewhat at the top, until in twenty minutes the alcohol was full from top to bottom. I brought it inside the house, and in a few minutes the precipitate began to take on a more attenuated appearance and to slowly decrease in height. In forty minutes it read 21 again. Readings of the height of the precipitate taken every ten minutes were as follows: 4.55 p.m., 100; 5.5 p.m., 93; 5.15 p.m., 80; 5.25 p.m., 50; 5.35 p.m., 21. Another instrument with the scale arranged in exactly the same manner had been hanging outside for a month or two, and read 50 during the whole experiment. The instrument in my room was next put into warm water, and I found that at a temperature of about 100° every particle of the precipitate would disappear.†

If allowed to remain in the water while it cooled, little stars or flakes would begin to appear in the alcohol, and when it had fallen to a temperature of 70° or 75°, the alcohol would be entirely filled with the precipate. If, then, the indications of the instrument are to be relied on, it is easy to get up a storm on short notice.

Suppose, when an instrument has been carried out of a warm room and the precipitate fills the alcohol from top to bottom, and it is left outside, as was done on the 1st of January, with the instrument hanging outside referred to above;—in such a case, after the instrument has been out some time, the column or precipitate will begin to shorten, even though the temperature remains the same; and it will be noticed that the bottom presents a more compact appearance. After about a week or ten days, the precipitate will have entirely lost its feathery appearance, except, perhaps, a little at the top, and will present a compact granulated mass filling about half the tube, if it is winter, and about one-quarter, if it is summer. If while the column of precipitate was shortening there was any considerable change in temperature, there might be some minor oscillations in the length of the column, but the whole tendency would be downward. When this state is attained, the precipitate dissolves very slowly in the alcohol, and the instrument is capable of going through considerable changes in temperature without much change in the height of the precipitate. Thus, suppose in the morning the temperature was 40°, and by noon had risen to 50°, the height of the column may show no perceptible decrease, because the dense crystals dissolve slowly, and the alcohol lacks considerable of containing as much as it could dissolve at the latter temperature; but when towards night the temperature again falls to about 40°, the liquid is nearly saturated; and, if by the next morning the temperature has fallen to say 32°, the liquid will be filled to a considerable height with light, feathery crystals which readily dissolve on a rise of temperature, or if the temperature remains stationary, settle to the bottom changed into the more compact granular crystals. To illustrate from observation—on January 13, the temperature in the room for about a week had been ranging from about 60° to 70°, and the height of the precipitate in the instrument had been almost steady at 23 on the scale, when the temperature in the room on the evening of the 13th fell to 52°, and light flakes of precipitate began to form. I knew the liquid was now super-saturated, and any further decrease in temperature would cause a decided precipitation. On the morning of the 14th, the temperature had fallen to 43°, and the height of the column of precipitate was 32 on the scale. I observed the instrument inside the house and the one outside, three times a day during January and February, and it was always found that the height of the two columns varied in opposite directions whenever the temperature changes inside and outside were in opposite directions.

I observed the instrument three times a day during the whole summer and autumn of 1881, and there was never an increase in the height of the precipitate without a corresponding fall of temperature, or a decrease without a corresponding rise of temperature. It will thus be seen that the instrument is not a "storm glass" or a "chemical barometer," but a chemical thermometer, and a very poor thermometer at that.

Do its indications bear any relation to weather changes? Yes; because temperature changes are closely related to other weather changes. In the summer, under an extended but moderately high pressure area, or anti-cyclone, there usually exists beautiful, fair, warm, settled weather, and the top of the precipitate will be even with the division marked "Fair." When showers come on, the air turns cool, and the precipitate rises to the division marked "Change." Whenever an area of decided low pressure passes over the country, the air is warm in front of it; and as the centre passes over, there is usually a sudden fall of temperature. This causes the precipitate to rise up to the division marked "Storm," and the wind in such cyclonic systems is always high, especially in their rear. In the winter the top of the precipitate is nearly always up in the division marked "Change," and as the weather is eternally changing, I suppose it may be considered about right. On the contrary, a decided anti-cyclone may in summer bring cool weather; and the precipitate will rise up into the division marked "Storm," accompanied by the clearest skies and delightful breezes. It is also common for rains to pass over without any material changes in temperature. In such cases the height of the precipitate will remain unchanged. The indications of the instrument are then sometimes right, sometimes wrong, like the negro's dumb watch, which was always right twice a day, but, as it gave no indications of the time when it was right, it was not worth much as a practical instrument.

## MIND.

THE Rev. S. J. Jerram delivered an able and interesting lecture at Ealing a week ago on "Mind," in which an approximately accurate view of the relations of mind with brain function was lucidly expounded. It is satisfactory to note the advance of a theologian towards science. We do not affirm that Mr. Jerram has shaken himself entirely free from the trammels of his professional habit of thought on these subjects, but his position is one which holds out an excellent promise of further progress. He is not prepared to say that "the mind *is* the brain," nor is any scientist prepared to make such an assertion; but he recognises the fact that physiological, as distinguished from purely metaphysical, inquiries are likely to play the most important part in elucidating the mystery of mental phenomena, and he has arrived at the perception that "no state of mind and no change in a state takes place without an act of cerebration;" at the same time making the necessary allowance for the possibility that the consciousness may hereafter be found to be located in the periphery as well as the centre of the nervous system, or diffused through the body as a whole. It is not necessary to point out to the scientific reader that these formulations of thought show a deeper insight into the subject than is common among those who study it from the ouside standpoint. The weakest part of Mr. Jerram's argument is that in which he strives to harmonise Locke's hypothesis that the mind at birth is as a blank sheet of paper, upon which anything may be written, with the doctrine of heredity; and in which, of course, he is compelled to assume the undemonstrable proposition, and, as we believe, the untenable position, that ideas are something else than the products of ideation, and that in some unexplained way *intuition* bridges over the chasm between primal agnosticism and consciousness. The logical process to which Mr. Jerram commits himself obviously necessitates that he should regard the physical organ of the mind as comparable with the cylinder of a phonograph upon which certain marks are impressed; in fact, as an organic or organised record of ideational impressions which forms part of its constitution, and is as much part of the inheritance as the matter itself. When any species of organised matter reproduces its kind, the form in which it is cast is as much part of the inheritance as the matter itself, and it is on this form character and quality depend. An educated cell brings forth as its progeny educated cells; and the education thus reproduced —"in its likeness," or "in his kind"—is something more than mere capacity for function: it is the recorded *result* of function. In this way an evil tree brings forth evil seed. Vice, or, as Mr.

---

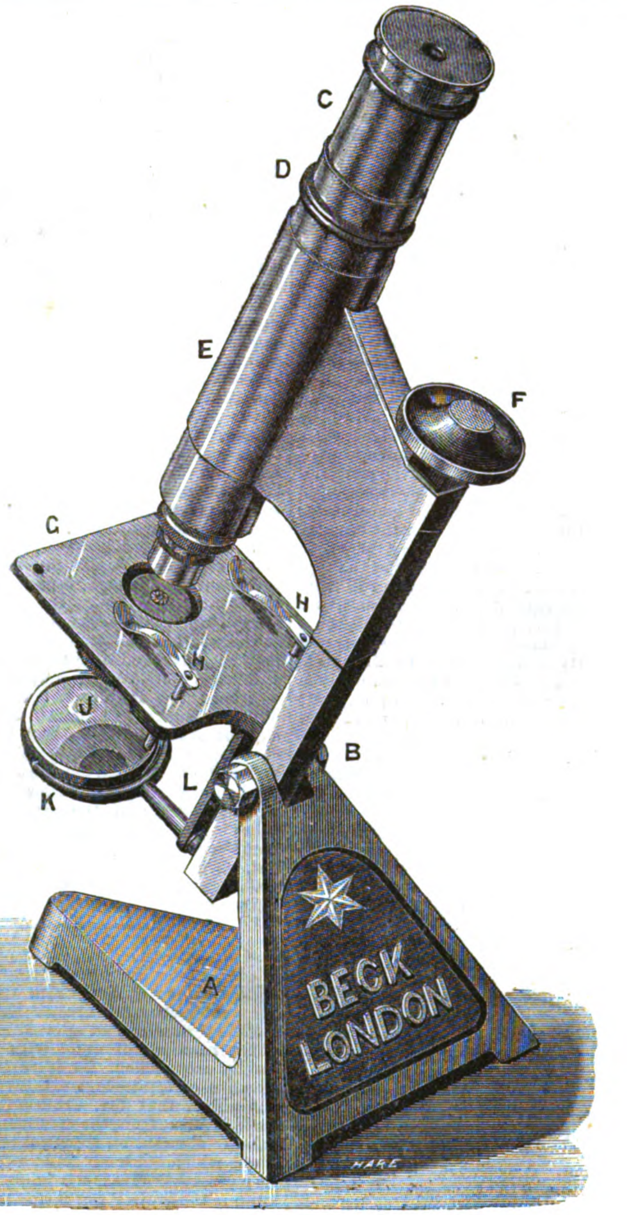
[*] By H. HELM CLAYTON, in the *American Meteorological Journal.*

[†] The first improvement was, I believe, made by Admiral Fitzroy.

[‡] Other ingredients besides camphor, I believe, are now included. I find it stated that two parts camphor, one part nitrate of potash, and one part salammoniac are put into the alcohol, and a little water added.

[*] I exposed an instrument for fifteen minutes to an electrical machine charged to high potential, and no change whatever took place in the height of the column in the tube.

[†] In order to make it dissolve rapidly, it is well to shake it up before putting it in water.



Jerram would say, *sinfulness*, is actually transmitted; not merely the possibility or probability of sinning, though these are implied. Mr. Jerram has gone so far that he must needs go somewhat further. Meantime we heartily endorse his conclusion: that which "metaphysics" represents, albeit the term has no precise significance, "the philosophy of mind as distinguished from that of matter......eventually comes to facts, the nature of which has not hitherto been solved, as all sciences of observation must do; but so long as it does not dogmatise, no danger is to be feared; and when it has reached the point beyond which it cannot go, that for the time is the true system of psychology, and we must patiently wait till further inquiries open out a more extensive field of knowledge.—*Lancet.*

## BECK'S "STAR" MICROSCOPE.*

IN the construction of this microscope Messrs. Beck appear to have reduced the cost of an efficient instrument to its very lowest limits, £3 3s. only being charged for it, including a 1in. and ¼in. objective, which, it is claimed, "are accurately worked, purely achromatic, and thoroughly suited for scientific research."

The microscope is nickel-plated throughout, with the exception of the case, which is solid in design, and contrived so that the instrument is steady in every position. It is made in two forms, with a sliding or a rack-and-pinion coarse adjustment.

The foundation of the stand is a solid cast-iron base, A, having at its top a hinge joint, B, which allows the instrument to be inclined at any angle, and is sufficiently firm to permit of its being placed horizontal for use with Wollaston's camera lucida. The body, D, has a draw-tube, C, with coarse and fine adjustments at N and F. The stage G has two springs, H H, the pins attached to which may be inserted in any of the four holes on the stage, and by their pressure (which can be varied by pushing them more or less down) will hold the object under them or allow it to be moved about with the greatest accuracy. The mirror J, besides swinging in the rotating semicircle K, is attached to a bar, L, with a joint at each end allowing a lateral movement, so as to throw oblique light on the object. An iris diaphragm, M, in which the size of the aperture is varied by revolving it in its fitting, screws into the under surface of the stage, and can be removed when other substage apparatus is required.

## PURE BUTTER.

IN Messrs. J. W. Queen and Co.'s *Microscopical Bulletin* for June, we find a brief account of some experiments with Dr. T. Taylor's method of discriminating between butter and its substitutes, made by Mr. J. B. Betts, of Philadelphia. We gave some notes in connection with this matter on p. 392, and Mr. Betts says:—

Some months ago the *Microscopical Bulletin* noticed the publication of a pamphlet by the Department of Agriculture, entitled "Analysis of Butter and Fats, by Thos. Taylor, M.D., Microscopist." Thinking it might be of interest, I sent for it at once, and must return thanks to the *Bulletin* for having put me on the track of this interesting matter. Having secured the information from the pamphlet of how to detect the presence of adulterations in butter, the next thing was to prove the work to my own satisfaction. To find the characteristic result promised for pure butter, I vainly tried samples of "Pure Creamery Butter" from the first-class groceries of our city, but somehow I could not get the result promised—even, strange to say, they all showed the unmistakable mark of admixture. It may be well here to quote the words of Mr. Taylor: "The test is a very simple one. If a few drops of sulphuric acid be combined with a small quantity of pure butter, the butter will assume first an opaque whitish-yellow colour, and after the lapse of about ten minutes it will change to a brick red. Oleomargarine made of beef fat, when treated in the same manner changes at first to a clear amber, and after a lapse of about twenty minutes, to a deep crimson."

In order to satisfy myself, I was fortunate enough to secure some butter made under my own eye, by the old-fashioned method of beating pure cream in a bowl. With this as a prime prover, I obtained the promised result, both when fresh and after several days. (In fact, the rancidity from age did not in any way affect the test.) But, to my amazement, all the samples afterwards showed clearly that some other fat was present; some were part butter, in which case the two fats separate themselves in the dish, the butter forming the centre, and the other fats forming a ring of dark crimson surrounding it, with a greenish cast if any preparation of lard enters in the mixture. The action of cotton-seed oil I am not able to state certainly, but believe it to have a peculiar granulation, which I intend to prove by mixture and test. There is a difficulty arises in examinations of this character which must be borne in mind by any one inclined to test his table butter, that it is almost impossible to buy butter after it becomes known that the test is being made, the buttersellers seeming to have a great lack of confidence in the test. It is the intention of Mr. De La Cour and myself to give a public exhibition of the tests before the Microscopical Society of Camden at an early meeting and *invite samples* from dealers, but we have no fear of our powers being overtaxed by the number presented. The peculiar crystallisation of the various fats in cooling is another easy method of detection, but a description thereof would be too lengthy for the time at my disposal.

## PAPER NEGATIVES.*

ONE of the questions at present, and for some time past, exercising the photographic mind is that of a substitute for glass for landscape work—a substitute which, while giving all the good qualities and offering all the conveniences of glass, shall be free from the serious objections of weight, bulk, and fragility of that substance. Despite many years of patient search in that direction, we seem now as far off the goal—a *perfect* substitute—as ever; and photographers have recently shown a tendency to accept the sort of compromise which paper as a support offers them. Numerous have been the processes, some patented, devised for the purpose of rendering paper translucent or transparent, and depriving it of its "grain"; many also have been the attempts to introduce a flexible and transparent film-substitute, composed of collodion, celluloid, guttapercha, and other materials, but no great success has attended such efforts, owing mainly to the great expense of the material and the trouble involved in its use. Paper, however, even of good quality, is a comparatively cheap material, and if it can be utilised with advantage, so far as quality of result and facility of manipulation are concerned, many a tourist will rest content to put up with such minor inconveniences as the longer time required in printing.

Notwithstanding the vast amount of attention that has been given to the subject of paper for negative purposes from the very earliest days of photography, it is probably the case that many modern experimenters have entirely failed to grasp fully the requirements of the paper negative process of to-day. In the days of Calotype and waxed-paper processes, the sensitive silver salts were formed in the body of the paper; hence, in order to obtain an image as free as possible from "grain" caused by the texture of the paper, it was absolutely necessary that the latter be perfectly homogeneous in its internal character, as well as smoothed and polished on its exterior surface. It was in the combination of these qualities that the old "Causon" and "Turner" papers excelled all others, and gained such a reputation for the special purposes referred to.

In order to explain the action of a coarse-grained paper in giving granularity to the image, we will digress for a moment. Suppose, for instance, a (theoretically) perfectly homogeneous paper is saturated with, say, potassium bromide, and afterwards floated on silver nitrate. Silver bromide will be formed in the body of the paper in a state of uniform division—that is to say, will be evenly intermixed in the minutest particles with the almost grainless pulp of the paper support. Consequent upon development a correspondingly grainless image will be the result.

If, on the other hand, a coarse-grained paper be used, or one which shows the "mesh" distinctly, we shall have the potassium bromide unevenly absorbed, the "pores" or interstices of the paper holding more than the coarse particles of solid pulp. Consequently we have the silver bromide formed in a coarser or less uniform state of division. From this it may be seen that it is not the grain of the paper *directly* which causes the granularity so often found in the image, but really the uneven distribution of the sensitive salt which the granularity of the paper causes. In fact, a structureless negative (on glass), printed through a sheet of paper of moderately even texture, will show far less granularity than would a paper negative made upon the same kind of paper.

---

* *Journal* Royal Microscopical Society.

* From the *British Journal of Photography.*

Arguing from this, it would appear that when an emulsion is applied to the surface of the paper only that the difficulty of securing freedom from granularity is overcome, and such, no doubt in the abstract, really is the case. But it is just here where experimentalists, and perhaps manufacturers, fail to recognise what is required. Thus, given a paper of fine and even structure and smooth surface nothing would appear easier than to apply a layer of structureless collodion or gelatine emulsion, and, as a result, to secure a grainless and perfect image on development. But practically, and in the absence of precautions, the matter is not so easy. The pulp from which the paper is made may be of the finest, and structurally the paper itself may be beyond reproach. Fine, however, as may be the internal composition of the paper, its surface, when first made, is, as most of our readers are aware, decidedly rough, this roughness being subsequently removed by "calendering," or by the combined application of heat and pressure, which produces a surface of almost any degree of fineness and even gloss.

This artificial surface disappears, more or less, under the influence of moisture; consequently it can easily be seen how, upon the application of a warm gelatine emulsion to such a paper, the surface swells and partially resumes its original rough character, and, practically, a *cast* is formed in gelatine emulsion, of which the uneven paper surface is the matrix. Here it is quite possible that the paper itself, when dry, may be so entirely free from apparent structure as to show not the slightest grain when printed through, and yet the negative image, if stripped and printed, will give most emphatic evidence of a paper grain. For positive work this matter is not of such high importance as in the case of negative paper, because a comparatively thin image is viewed by reflection; whereas the value of a negative depends upon its varying power of arresting and transmitting light, and each difference in the thickness of the film produces an effect identical with that of an increased deposition of silver by the developer.

What is really wanted is a careful preparation of the surface of paper intended for negative work with an isolating medium, which shall prevent the fibres of the paper from swelling under the warm emulsion. After that, the production of a homogeneous deposit of silver follows as a matter of course, and the tendency to granularity arising directly from the structure of the paper remains the only trouble to be combated.

We have made these remarks in consequence of having recently seen many negatives taken upon unsuitable paper—unsuitable, that is to say, for negative work, though quite adapted to positive printing—while we are aware that it is quite possible to produce prints from paper negatives, which will defy the keenest scrutiny to distinguish them from prints from glass negatives. It is, we believe, but a question of a very short time before we shall find paper negatives firmly established amongst us for many purposes; a few prejudices have to be overcome, and a few mechanical and manipulatory details arranged, and then glass for landscape work will find a powerful rival in the field.

## A FAST STEAM-YACHT.

THE *Mechanical Engineer* describes the *Stiletto*, a steam yacht built by the Herreshoff Company, and claims that this craft is the fastest afloat. She is 95ft. long over all, by 11ft. beam, and 7ft. 9in. depth of hold. Her model is peculiar, and all that we can say about it is what the Herreshoff Company wish to make public; her bow lines are nearly straight, and she is sharp at both ends, with a round bottom; proportion of beam to length $8\frac{6}{11}$ths. The engine is of the Herreshoff pattern with 12in. and 21in. cylinders by 12in. stroke, driving a 4ft. screw with 6ft. 6in. pitch. The engines can drive this 450 revolutions per minute, if required. The boilers are of the Herreshoff pattern, and to those unacquainted with them need a brief description. They are "pipe boilers" so called, and are made in sections like steam radiators. These sections are disposed over and around the furnace, and any one of them can be quickly detached, in case of need, for repairs. The water is fed in at the top and is converted into steam in its passage down, and emerges into a stand-pipe or separator at one side of the sections; from this it goes to the engines. The advantages of this system are great lightness and efficiency. The whole boiler is heating surface, and being without a shell is capable of carrying very high pressure. The *Stiletto* works under 150lb., that being sufficient to attain great speed, but we presume the boilers would stand 200lb. just as well. Our readers at a distance may be interested in knowing that Mr. John B. Herreshoff, the principal of the Herreshoff Company, is totally blind, and has modelled all his vessels by the sense of touch alone; he has literally felt the lines out. The fastest vessel that swims to-day, irrespective of size, is doubtless the steam yacht *Stiletto*. She recently ran from this city to Sing Sing on the Hudson, 30 miles by the chart, in 77min. from the start. This is an average of 23·7 miles per hour, but is not an expression of her highest velocity, for she was not put to speed from the start, but ran some miles under easy steam. The *Stiletto* outran on this occasion the *Mary Powell*, hitherto the fastest boat on the river, beating her with ease. The *Mary Powell* was fully alive to the occasion, and did her best, but that was not enough. The *Stiletto* has achieved by this adventure a wide notoriety. In closing, we may give the secret—if it may be so called—of the *Stiletto*'s great speed. This results from her lightness, great engine-power, and fine lines; but the first two qualities are paramount. She weighs only 28 tons and develops 450-h.p., having 16-h.p. per ton of displacement. This, as all engineers and constructors know, is simply tremendous in its possibilities. The *Stirling Castle*, the fastest merchant vessel afloat, has only 3 to $3\frac{1}{2}$-h.p., per ton of displacement, while ocean steamers generally have only from 1 to 2-h.p. per ton of displacement.

# SCIENTIFIC SOCIETIES.

◆

## ROYAL MICROSCOPICAL SOCIETY.

MEETING of June 10th, 1885, at King's College, Strand, W.C., the President (the Rev. Dr. Dallinger, F.R.S.) in the chair.

Mr. Suffolk exhibited a collecting bottle with flat sides, which had been ground and polished. Everyone must have found the inconvenience of the ordinary round bottles, through which it was impossible to see anything clearly, and therefore would welcome one which had flat sides worked to a true surface, through which an ordinary objective could be focussed and would give perfect definition. The bottles were made by Mr. Stanley.

Prof. Bell said that flat bottles had been made for some time, but they were not to be had except from foreign makers. He believed that some had been used at the College of Surgeons; but the glass was very bad, and their use had in consequence been discontinued. Round bottles were very inconvenient, and he hoped that as an English maker had taken up the matter, they might be able to get flat ones of different sizes.

Prof. Stewart said they had almost ceased to use these bottles at the College of Surgeons, because the sides were so rough and the tops so far from flat as to be of very little value. The first samples were very much better, but the later ones were so bad as to be practically useless.

Prof. Stewart called attention to a specimen he exhibited under the microscope, showing the special eyes of chitonidæ described by Prof. Moseley. He also showed a model of the species of *Chiton*; but having found at the College of Surgeons a better specimen than the one from which Prof. Moseley's model had been made, he had brought it to the meeting. A section showed that the shell was raised into numerous corneal elevations, beneath which it was tunnelled out in a very distinct manner. Behind the elevation was a substance like a lens, and below this a space caverned out, at the lower end of which was a series of rods, from which a number of filaments proceeded, together with some pigmented matter forming a sort of choroid coat, a part of which projected forwards, forming an iris. The optic nerves proceeded directly upwards, so that there was no turning over as in the eyes of the pectens. In addition to the specimens exhibited, Prof. Stewart illustrated his remarks by drawings on the black board.

Prof. Bell said that he thought the Society should know something of the kind of work which was being done by Mr. Hill, who had been assisting Prof. Moseley, and had made the model exhibited. Whatever the general opinion of models might be, those who had any experience could speak as to their great use for purposes of illustration in class instruction.

Mr. Wright's letter with reference to Dr. Anthony's criticism on his note on the structure of the tongue of the blow-fly was read as follows:—The February number of the *Journal* of the Royal Microscopical Society is only just to hand. At page 174 I note Dr. Anthony's letter read at the January meeting of the Society as to my observation on the structure of the tongue of the blow-fly. I have looked up his paper on "The Suctorial Organs of the Blow-fly" in the June number of the *Monthly Microscopical Journal* for 1874, and I at once disclaim any previous knowledge of it. I can only now regret that it was unknown to me, as I should have certainly given all the credit to Dr. Anthony for the discovery of the "suctorial organs," which he so well earned by the long and arduous work he bestowed on this subject during the whole of a blow-fly "season." After speaking of his numerous dissections, he says: "Many a hundred coaxings were necessary to get the parts into definite positions ere I could satisfy myself of the arrangement of what I will venture to call the 'suckers' attached to the pseudo-tracheæ of diptera." These suckers he likens to "earlike appendages," "mouse ears," or "bats ears." Before I sent the slide of the proboscis in September last, I consulted all the most recent standard works on the microscope, as well as Mr. B. T. Lownes's "Anatomy and Physiology of the Blow-fly," and I could not glean any information that the details of structure described in my letter had been observed. This description was only such as would suggest itself to anyone conversant with anatomy. I hope I may be permitted to make this explanation, so as to show that Dr. Anthony's charge that I have plagiarised, although not wilfully, must fall to the ground, and that it was, in fact, as he suggests, a "re-discovery." I wish to call attention to the fact that the proboscis of the blow-fly, as prepared and mounted by Mr. Sharp, requires no dissections or coaxings to display the leaf-like processes or "suckers" *in situ*. Under a sufficiently high power they, at the first glance, arrest the observer's attention—their visibility being entirely due to the mode of preparation, and to the highly-refractive fluid in which the object is mounted. I find with a $\frac{2}{3}$ Tolles of 65°, or a $\frac{1}{4}$in. of 90° (made 25 years ago by the late Andrew Ross), the "suckers" can be distinctly seen, although not with equal brilliancy to the performance of my Tolles's $\frac{1}{10}$ immersion lens. When viewed with the latter, each of the "suckers" appears as an actual protrusion of the lining membrane of the pseudo-trachea through a corresponding forked opening of the chitinous ring, and its expansion forms the leaf-like process or "sucker"; each of these has a longitudinal slit or fissure extending from the base to the apex. In some of the suckers the slit is seen with the margins in close contact, in others it is more or less widely open, and they all, on each pseudo-trachea, communicate with a central undulating channel running its whole length. The elasticity of the chitinous rings does not satisfactorily explain the way the suckers act. The opening and closing of the slit is most likely effected by some inherent contractile power in the sucker itself, which probably is under the control of the insect's will. In the imbibition of fluids, capillary attraction must also play a very important part; and it seems possible that the so-called "suckers" may maintain a regulating action in this respect, and thus prevent what would be an injurious or even fatal absorption. I think if Dr. Anthony will examine a proboscis mounted by Mr. Sharp's method, he will candidly admit that his illustrations need something more than "small alterations and corrections" to bring them "up to date." As no allusion to his paper was made by any of the members present at the November meeting of the Society, the inference is that, with the exception of those to whom Dr. Anthony has personally shown his preparations and dissections, the "suctorial organs" up to that time were generally unknown. I used the term "endoderm" in the same way Mr. B. T. Lownes has done in his work on the "Anatomy and Physiology of the Blow-fly," to indicate "the innermost cuticular layer of the integument." It is likely that the "suckers" consist of the three layers of the integument; certainly they have an outer layer of the protoderm, which Mr. Lownes thus describes ("Anatomy and Physiology of the Blow-fly," p. 9) as "transparent and continuous over the whole surface of the insect, investing all the appendages and processes of the skin, even the hairs, and covering the surface of the eyes. It appears to be continuous with the lining membrane of the tracheal system, and to extend throughout the digestive cavity, even although it is somewhat modified in the latter." I beg to send a slide of the Blow-fly proboscis (mounted by Mr. Sharp) showing the "suctorial organs," as a donation to the Society's cabinet. Mr. Sharp also sends for publication his method of preparation and mounting in the biniodide of mercury solution.

The president said Mr. Wright's communication placed the matter in a somewhat different light, and gave them additional information.

Mr. Suffolk said he had examined Mr. Wright's first specimen, and he had also made a similar specimen of his own; but the conclusion he came to was that the appearances described were due to some sort of diffractive effect, and that they were, in fact, out-of-focus appearances.

Mr. J. Mayall, jun., called attention to the fact that a Nobert 19-band test-plate had been successfully mounted in Prof. Hamilton Smith's medium, having a refractive index of 2·4, the result being to render the lines very much more visible than had been the case before. The preparation was made by Dr. Van Heurck, and was attended with considerable difficulty. He now thought it possible to improve upon the photo-micrographs of the 19-band test-plate made by the late Dr. Woodward, of Washington, for the lines being mounted in the highly refractive medium could be illuminated by immersion means, so that an objective of higher aperture than any employed by Dr. Woodward could be used to resolve them. He hoped to try some experiments in photographing this test-plate by means of Powell and Lealand's new homogeneous immersion of $\frac{1}{12}$th of 1·5 N.A.

Mr. Crisp said that they had received from Prof. W. A. Rogers, of Cambridge, U.S.A., a collection of upwards of 60 slides, showing the action of a diamond in ruling lines upon glass. The series was accompanied by a descriptive paper which, when printed in the *Journal*, would enable the Fellows to compare it with the slides.

The president said that Prof. Rogers had expressed the hope that someone might feel sufficiently interested in the subject to make a careful study of the slides. They had not yet had any opportunity either of examining the slides or reading the paper, but their best thanks were due to Prof. Rogers for his valuable donation.

A vote of thanks to Prof. Rogers was carried by acclamation.

Mr. Crisp, in exhibiting Theiler's "Universal Pocket Microscope," read some of the press notices of it, and commented on the extravagant manner in which it had been referred to in some journals.

Dr. Maddox said that since the last meeting he had continued his experiments on the feeding of insects with bacilli, and had fed both the wasp and the blow-fly, formerly alluded to, with the Anthrax bacillus. They had lived on through the month until that very hot day when the thermometer rose to 136° in the sun, when they succumbed to what he believed was heat asphyxia, so that he was unable to attribute their deaths to any effect of the bacilli.

Mr. Waters read his paper on "The Use of the Avicularian Mandible in Classification," the subject being illustrated by drawings.

Mr. Cheshire described a method of mounting, which he had found of great advantage with the particular class of preparations with which he had lately been engaged, and he proposed to give some account of it as likely to be of interest to others similarly working. All present were, no doubt, aware, of the great value of glycerine as a mounting medium for delicate structures, Canada balsam being destructive to soft tissues and cells. Glycerine also possessed a marvellous immunity from freezing. The great difficulty about its use for mounting purposes generally arose from the fact that when once the surface of glass had been contaminated with glycerine it was very troublesome to get rid of. The reason of this was that the surface of glass, however well polished, was not mathematically true, the most highly-polished surface having its surface covered with very fine lines, and these not all running in the same direction. In fact, if marks were made upon a piece of glass with glycerine or turpentine, the traces of them could be distinctly seen after the glass had been well rubbed. The first thing, therefore, to do was to get a perfectly clean slip, and having put it upon the turntable, to make a ring of Canada Balsam dissolved in benzole. The next thing was to get a perfectly clean cover-glass, and in order to hold this conveniently he had found it an excellent plan to mould a small piece of bees'-wax into a semicircular form, having about the diameter of the cover, which, if slightly pressed upon the upper side of the cover, adhered to it sufficiently to form a kind of handle by which it could be lifted; and if it were turned upside down, it would stand upon the corner of the table until it was wanted for use. A ring of the balsam was then put upon the under side of the cover glass of the same size as that upon the glass slip. The next step was to select the object, and he had found that the most convenient things in which to keep stained objects were the small china saucers, which were to be bought at the artists' colour shops. They were much better than watch glasses. He then took up a small drop of glycerine, and put it in the ring of balsam which had been made on the slide (and for this purpose he had found nothing better than the ivory handle of a small dissecting knife), and then the object was placed on the slide. In doing this he had found nothing so useful as a watchmaker's eyeglass, and to save the inconvenience of having to take it up every time it was wanted he had it fastened round his head with a piece of elastic web, and when not in use it was pushed up upon the forehead. Having placed the object on the slide in proper position, it was well to remove all superfluous glycerine, and the best way to do this was with a small sable brush, sucking off the fluid when the brush was full. Another drop of glycerine was then put upon the under side of the cover glass, which was then placed in position on slide, the two rings of balsam were slightly pressed together, they adhered immediately, and the thing was done. A small amount of practice would enable anyone to judge exactly how much glycerine was required to fill the space; but if it happened that too much had been used it would force a small channel for itself and squeeze out through the balsam, which would afterwards close together again quite tightly. The only thing remaining to be done was to put on a coating of Hollis's glue to prevent the balsam from setting, and by adopting this system it would be found that the cover could be pressed down just as much as was required. The usual process was to mess the glass with glycerin first and then, of course, the cement would not adhere properly, and the result was leakage. Mr. Cheshire further illustrated his meaning by drawings upon the black-board, and by the exhibition of specimens, which were handed round for inspection.

Mr. J. W. Groves said that Mr. Cheshire's first statement was that delicate structures and cells could not be seen in balsam-mounted specimens; this, however, he was prepared to deny, knowing from experience that there was no difficulty in the matter. With regard to Mr. Cheshire's suggestion of sticking the clean cover on a piece of wax and letting it remain with the under side upwards until wanted, he could only say that if a cover was left like that in his laboratory for even two or three minutes, it would get so coated with dust as to need cleaning again before it could be used. The plan of cleaning up the excess of glycerine by means of a brush was the one he usually adopted. With regard to putting two rings of balsam, there were, he thought, other things which would do better, and he should suggest Miller's cement instead, if there was no glycerine upon the slide; and instead of putting glycerine on the under side of the cover, a better plan was simply to breathe on the cover—it answered quite as well, and was much less trouble. In using a watchmaker's eyeglass, a far more convenient way was to have it mounted upon a piece of light spring wire fixed in a heavy block as a stand; it was then very easy to bend it over the object, and apply the eye when required, and the moment the head was moved away it sprang on one side, without any attention being required by the worker.

Mr. Cheshire said that notwithstanding the remarks of the last speaker, he must still persist in stating that there were some structures which were absolutely destroyed by mounting in Canada balsam. For instance, there was a certain part of the dorsal vessel which contained cells which could not possibly be mounted in balsam without destruction. Certainly if any one could so mount them without, he should be very glad to see them.

Mr. Groves said he would willingly accept the challenge, the results to be shown in that room.

Mr. Cheshire said that the proposal to breathe upon the cover-glass was just undoing the thing he had been advocating, and as regarded the difficulty of keeping the cover-glass clean, if mounting was done in such dusty places the cover might be placed with the underside downwards if necessary.

The President said they were very much obliged to Mr. Cheshire for his remarks. There were doubtless some amongst them who would derive useful hints from the communication. They would also be much interested in seeing the results of the mounting in balsam, concerning which the challenge had been accepted.

Prof. M. N Dutt's letter was read, accompanying some unknown powdery substance found near Delhi.

"My method of mounting the proboscis of blowfly in solution of bin. mercury is as follows:—Apparatus necessary, two pieces cut from a glass slip, 1in. long by ¼in. wide, a weak spring clip, and a wide-mouthed bottle containing methylated spirit. Kill the fly by dropping it into boiling-water, cut off the head, place it on one of the bits of glass, squeeze with finger till tongue protrudes and lobes expand; then gently nip with the other bit of glass and put on weak clip to hold in position; place the whole in the methylated spirit, and leave there for an hour or more. On releasing the proboscis from the glasses, the lobes will remain expanded: cut off the proboscis and place in spirit till all the air is removed. Then place in water for half-an-hour, then in weak solution of biniod. mercury (half water and half saturated solution) for two or three hours, then in the full strength solution for twelve hours. When the proboscis is put in the weak mercury solution, it will most likely curl up (the lobes), to prevent which, I place it on a slide when taken from the water, and put on a cover with a weak clip to hold it in position, and then run the weak solution of mercury under the cover, and do the same when transferring from the weak solution to the full strength solution. Mount in shellac cell, and use shellac for securing the cover. I find it safer to use for the final mounting, a solution of the biniod. mercury slightly weaker than saturation, as if full strength, crystals will develop in very cold weather."

---

**Benzol Magnesia.**—German journals allude to the efficacy of "benzol magnesia" as a grease eradicator. It is prepared by saturating calcined magnesia with benzol. A little of this powder rubbed on a greasy stain on paper, or any fabric, will remove it; but old stains may require a repetition of the process. The mixture is said to be excellent for cleaning windows.

## SCIENTIFIC NEWS.

THE *Building News* directs especial attention to a valuable report on a new economical and fireproof cement by Mr. G. H. Hunt (Verity and Hunt), which it publishes in its last issue. The cement is made by Messrs. Joseph Robinson and Co., of Knothill, near Carlisle, and is equal in every respect to Keene's, Parian, and other high-class cements, used in the best work, while its cost will admit of its employment instead of the ordinary lime, sand, and hair plaster, which at present has to be put up with where expense is an object to be avoided. The new cement is fireproof, very hard and strong; it takes paint well at once, and can be used at any time of the year, or in any weather; and can, if desired, be brought up to a splendid polish. Capt. Shaw, the chief of the London Fire Brigade, believes "it would be more effectual in preventing the spread of fire than any other of the common plasters or cements generally used," and his opinion is not lightly formed. The cement has found favour wherever used, and seems likely to create considerable stir in the building trade.

Although he had reached the seventy-eighth year of his age, many will hear with regret of the death of James Kitson, of Leeds, an English mechanic of the first rank. Commencing life as a student of the Mechanics' Institute, in Leeds, he rapidly rose in his profession, and soon made a name for himself as a builder of locomotives when railways came into vogue—a reputation which has clung to the firm ever since. Mr. Kitson, when he ceased to be a pupil of the Mechanics' Institute, filled several of its offices in turn, and ultimately became its president. Mr. James Kitson was, in fact, a scientific mechanic, and a commercial and public man, whose influence in Leeds was deservedly very great. Many will hear with regret that his long and useful life has ended.

M. G. Witz, of Rouen, died recently at the early age of forty-eight. He was a conspicuous member of the Industrial Society of his native town, and was a notable contributor to the progress of chemistry. We mentioned in this column recently his observations on the presence of ozone in the atmosphere of Paris during the cholera epidemic, but his most important work is probably that in connection with the chemistry of cellulose.

The death is also announced of the venerable and distinguished Swedish physicist, Prof. A. W. Eklund, at the age of ninety years.

Small planets are now becoming so numerous that the announcement of the discovery of a new one is wisely delayed until its novelty can be verified. It appears that Dr. G. Palisa, of Vienna, discovered No. 248 early last month, which increases his list to forty-seven.

M. F. Folie, of the University of Liège, has been appointed director of the Royal Observatory, Brussels.

Mr. Bosworth Smith has been appointed mineralogist for the Madras Presidency, and has been specially requested to compile a complete index to the mineral wealth of the presidency, and to commence, in consultation with other officers, a mineralogical survey.

At a recent meeting of the North of England Institute of Mining and Mechanical Engineers in Newcastle-on-Tyne, Mr. T. W. Bunning read a report on experiments made at Saarbrücken on the influence of coal-dust in explosions. Mr. Galloway, who was present at some of these experiments, stated that if the coal-dust were removed from the vicinity of the shot-holes, or kept watered for a space of six yards, the risk of explosion was removed.

The 53rd annual exhibition of the Royal Cornwall Polytechnic Society will be opened on Tuesday, Sept. 22nd. Medals and prizes are offered in mechanics, naval architecture, chemistry, and electricity, fine arts, photography, and natural history, and there are competitions with prizes in maps and essays (Lander competition), art needlework, and British lace. Full particulars can be obtained from Mr. E. Kitto, F.R.Met.Soc., Secretary, Polytechnic Hall, Falmouth.

The first section of the Barrow-in-Furness tramways was inspected by the representative of the Board of Trade last week, and will shortly be in full work. The line runs from a point near Furness Abbey to Roose, and has a total length of about four miles. The gauge is 4ft.; the rails were manufactured by the Barrow Steel Co., and weigh 84lb. to the yard. The locomotives are being made by Messrs. Kitson, Leeds. The line is a single one, with passing-places three chains long at intervals of a quarter of a mile.

At the beginning of the next college year, in the autumn of 1885, Professor Thurston, formerly of the Stevens Institute of Technology, will assume the position of "Director" or presiding officer of Sibley College, Cornell University, Ithaca, New York State, and will undertake the duties assigned him by the trustees of the University, of recommending a revised course of instruction in mechanical engineering and of tuition in the mechanical arts. Sibley College was erected by the Hon. Hiram Sibley, of Rochester, New York, and will be devoted to this department of instruction. Its recent additions, in the form of enlarged buildings, added tools, and new collections of apparatus, make it an exceedingly well-equipped school; and it is stated that the trustees have declared an intention of doing all in their power to make it the equal of any such school now existing, and to give it every really desirable facility for its work. With the enormous wealth of Cornell University under their control, that will probably be easily within their power.

The Darwin Medal for 1885—founded by the Midland Union of Scientific Societies—has been awarded to Mr. W. J. Harrison, F.G.S., Science Demonstrator for the Birmingham School Board, for his original researches in connection with the geology of the Midlands.

On Sunday, June 28, an important portion of new railway was opened at Market Harborough. The whole of the Midland main line traffic has ever since 1857 passed over about a mile of the London and North-Western Railway, and great delays have been caused to important traffic. On the above date two new lines were opened, perfectly distinct, and the Harborough and Great Bowden junctions removed.

At the meeting of the San Francisco Microscopical Society on June 10, a living book-worm, taken from an old Bible in Hebrew, belonging to the Sutro collection, was shown under the microscope and referred to Mr. Wickson for identification. The consideration of the subject announced for the evening "Pathogenic Bacilli," having to be deferred until the following meeting, Mr. Banks gave an interesting demonstration of the electric light in its relation to microscopy. He first showed a miniature incandescent loop lamp, actuated by a sulphuric acid and sulphate of mercury battery. For purposes of microscopical illumination, the incandescent electric light possesses the great advantages of extreme whiteness and intensity. With regard to the batteries actuating these lamps, there are still some difficulties to be overcome, but there can be scarcely a doubt that it is a question of only a short time when, with increased steadiness, duration of action, and cheapness of battery power, the electric light will be superior to all other methods of artificial illumination for microscopical and microphotographic purposes. Mr. Banks also showed, under the society's largest microscope, the electric spark in its passage between the terminals of a ¼in. spark induction coil, attached to a Grenet bichromate solution battery. Two vulcanite slides had been prepared, on which were fastened adjustable platinum strips connected with the battery wires, and terminating in brushes of platinum wire of extreme tenuity. The electric fluid, in its passage from one terminal to the other, formed a very attractive object under the microscope. One of the slides was used to show the effect on the electric spark, of interposing films of soot of different thicknesses. In its passage through these the current was deflected into meandering lines, around which scintillated showers of sparks. The particles of soot could be seen arranging themselves in symmetrical groupings around the terminals. In conclusion, Mr. Banks announced that he had sent for, and would soon be able to exhibit the Stokes-Watson apparatus for showing under the microscope the combustion of various metals in the electric arc. Their characteristic spectra can also thus be shown by the micro-spectroscope.

Mr. J. A. Youl says that there is now no doubt that the true *Salmo salar* has been successfully introduced to Tasmania, his last shipment of ova having arrived in excellent condition. An Australian paper says: "Out of 200,000 salmon ova, arived per *Yeoman*, 40,000 are now ascertained to be alive. Three hundred have already been hatched. A preserved specimen from which the ova was taken, and which has been sent out, and is now in the museum, indicates that the same fish which have been caught here are genuine salmon, after all."

At Nuremberg, on the 15th inst., an exhibition of machinery for the production of motive power will be opened, and continued until the 30th of Septemper. The chief object of this exhibition is to introduce labour-saving machines for small workshops.

On the authority of Sir Henry James, the late Attorney-General, we learn that misconception has arisen as to the inclusion of more than one invention in the same patent. The late Solicitor-General and himself have issued regulations, the effect of which is that the rules as to the inclusion of more than one invention remain as they were before the new Act was passed.

An abstract of the results of the experiments by Dr. Tidy and Prof. J. Dewar, carried out at Aylesbury with the A B C process of treating sewage, shows (1) That the A B C process produces a clear effluent free from suspended matter and devoid of smell; (2) that the effluent is uniform, notwithstanding the very varied nature and concentration of the sewage; (3) that as the strength of the sewage increases, the precipitation is more complete; (4) that the process removes over 80 per cent. of the total oxidisable organic matter; (5) that it precipitates 60 per cent. of the organic matter in solution, and of the residue left in the effluent at least two-thirds is non-albuminous, and therefore of a nature less liable to putrefactive and other changes; (6) that the process is carried on without nuisance, the sewage being immediately and completely deodorised, and the entire works free from any objectionable smell; and (7) that it produces a manure containing an average of 3·8 per cent. of ammonia calculated on the perfectly dry manure, or if with 20 per cent. of water 3 per cent. of available ammonia, and also 5 per cent. of phosphates reckoned as tricalcic phosphate of lime.

It will be remembered that the proceeds of the lectures delivered by Prof. Tyndall in the United States during 1872 were handed to trustees, with the view that the money should be devoted to the sustentation of science fellowships; but a difficulty arose, and the money having been invested, now amounts to about £6,500. At the suggestion of the trustees, Prof. Tyndall has directed that the fund shall be equally divided between Columbia, Harvard, and Pennsylvania universities.

**The Institution of Permanent-way Inspectors.**—At the general summer meeting held on Saturday week, the following persons were elected:—As members: Messrs. S. W. Jones, East Indian, Bengal, India; J. Richards, L. and S.W., Basingstoke; J. Pilling, Cheshire lines, Baguley; W. C. Summerfield, L. and N.W., Coventry; J. Jobbins, L. and N.W., Smethwick; F. Giles, G.N., London; Alfred Ivins, G.W., Dorchester; Clarke White, Midland, Hellifield; George Rodgers, Midland, Chesterfield; Wm. Genders, jun., M.S. and L., Sheffield; Samuel Genders, M.S. and L., Retford; Wm. Steel, N. and S.W. Junction, Acton. As Associates: Messrs. W. H. Elliott, Chief Signal Inspector, G.S. and W. of Ireland, Thurles, Ireland; C. Cornes, Signal Inspector, Midland, Luton; Thos. Henry Knight, New Works Inspector, Midland, London; Chas. Bindley, Foreman Carpenter, Midland, London; Thos. Winfield, Foreman Platelayer, Midland, Nottingham; Henry Barlow, Foreman Platelayer, Midland, Nottingham. As students: Messrs. J. F. Hewitt, Somerset and Dorset R., Glastonbury; Wm. Smith, Midland, Ambergate.

**Varnish for Ferrotype.**—The solvent should be highly rectified benzole; and the resinous body most suitable is gum dammar. Crush the gum, and having placed it in a tall bottle, pour in the benzole and shake up at repeated intervals until dissolved. Allow to stand until quite clear above the sediment, then decant carefully into a clean bottle, and dilute with benzole until of the consistency desired. Good varnish can be made by dissolving Canada balsam in benzole.

# LETTERS TO THE EDITOR.

## RED STARS—16 CYGNI, 53 OPHIUCHI, &c.—ORBIT OF 61 CYGNI, AND STARS SEEN BY DAYLIGHT.

[24438.]—THE red star B.Add 27 Geminorum mentioned by Mr. Franks in letter 24367 appears to be identical with 12 Geminorum; at least Se. identifies it with B.A.C. 2029, which is certainly 12 Gem. 10, 11, and 12 Gem. are close together. I examined these three stars and all prominent ones near them some years ago, when I was endeavouring to identify the triple star H. V. 55; but I have no note of any red star here. However, I have some reason to believe that my eyes are not so sensitive to red as to some other hues—at least, I well remember, when observing one evening some six or seven years ago at Hardwick, with my deeply-lamented friend the Rev. T. W. Webb, being especially struck with the fact that his sight seemed far more sensible to impressions of red or orange in the colours of some red stars we observed than my own was. B. 607, to which Mr. Gore refers in letter 24391, page 367, is *m* Lacertæ (1 Hevel, Piazzi xxii. 36). It is 5·0 mag. in Piazzi, and was entered by Sir J. Herschel as No. 1746 of his 4th catalogue of double stars, having two companions of the 12th and 13th magnitudes at estimated distances of 20″ and 60″ in the direction of 180·0° and 185·5°. A.B. was measured at Cincinnati, 178·5° : 27·2″; mags. 6·0, 11·0, 1879·522; colour of A not noted. It is curious that Sir J. Herschel did not note the colour if the star was at all red when he observed it, as he has frequently called stars *red* in which other observers have seen no indications of such a hue. He calls A 6 mag.; it is 5 mag. in Houzeau. Some of Mr. Burton's magnitudes seem very low.

The magnitudes of 16 Cygni, about which Mr. Gemmill inquires in lettter 24391, were taken by Smyth from Piazzi. This is invariably the case in the "Cycle," where Piazzi gives both components of the stars observed by Smyth, and Smyth always assumes the magnitude of the bright star from Piazzi in the cases where the companion was too faint to be seen at Palermo. I suspect that the small "$^{s}$" of $\alpha^2$ Cancri was accidentally omitted by either Mr. Franks or myself when reading the proofs of the last edition of "Celestial Objects." By the way, Mr. Gemmill should write B. 212, and not β 212, &c. B. is the conventional term for Birmingham, and β for Burnham. I am afraid I can tell Mr. Gemmill nothing at present about de Zach's magnitude of α Draconis. Baron de Zach did little or no observing after leaving Genoa in 1826, and he died of cholera in September, 1832, while the date of Smyth's "measure" of his *comes* to α Draconis is 1834·41. His magnitude is, of course, assumed from Piazzi. I fear that my language would be, too frequently, the language of imprecation before I succeeded in unearthing de Zach's observation of the magnitude of Thuban from the forty odd volumes of the "Monatliche Correspondenz," and the "Correspondance Astronomique," to say nothing of his other works.

The statement about 16 Comæ being the "lucida" of that constellation is taken from Smyth's Cycle II. p. 267. Smyth says of 53 Ophiuchi: "It is followed by the two 8th magnitude stars mentioned in Piazzi's Note 150." He does not show these stars in his diagram, but he undoubtedly referred to C and D, although D, strictly speaking, is about 10″ or 12″ *preceding* 53. Argelander rates C 8·2 mag. and D 9 3 mag., the *comes* of 53 being 8·5 magnitude. These are the two stars observed by myself in 1872 and 1875, and in company with Mr. Read in 1881. On turning to Piazzi's note in the Palermo Catalogue of 1814, I was astonished to find that his words are "19″ temporis sequitur alia 8 æ mag. 10′ ad Austrum, et 41″ temporis alia 8 æ magn. 5′ ad Boream." The first of these is, of course, C, which, according to Bessel, follows A of 53 Ophiuchi at 18·2 sec., and is 10′ 5·6″ to the south of it, but where is the other? There is certainly no 8 or 9 mag. star near Piazzi's place, and unless he has made some error, the star must be a variable.

I suspect, however that Piazzi has omitted the word "præcedit" before the second "alia," and the star is then an 8 8 mag. Arg., which precedes 53 Oph. about 32·3s., and is 3′ 58″ north of it, according to Bessel; Piazzi's differences of A.R. and Decl. being in all probability rough estimations. ♅ called A of 53 Oph., white or reddish white, and B pale red in 1781 and 1782; H. and So. both blue or bluish white in 1821; Σ. both white on 5 nights in 1835; Smyth, both bluish in 1836, and A greyish and B pale blue in 1850; Se. white, blue in 1856: Main, both white in 1861; De., very white, reddish blue in 1863, and white, blue in 1871 and 1872. I called A pale yellow, B lilac in 1872 and 1875 with refractor, and A pale yellow, B blue in 1875 with reflector. There is, of course, no evidence of change in the magnitudes of C and D. Inasmuch as Dawes, from the mean of 17 nights observations, makes the magnitudes of the components of η Coronæ 5·7 and 6·0 respectively, while Dembowski, as the result of over 100 nights between 1862 and 1878, rates them 5·8 and 6·2, I think they may be considered as approximating very closely to a pair of average 6th-magnitude stars. Struve's observations being made by daylight, his estimates are probably too high. I took the distance of the components in 1831 from Struve's measure, the mean of three days' observations in 1831·63. Doberck's elements, the best I know, give for the distance at the time of Struve's observation 0·87″, and at the time of Dawes's 0·89″; the difference between observation and calculation being only 1-100th of a second—a quantity which, like the weight of the hippopotamus in the problem, may be neglected.

The two stars of 61 Cygni (about which Mr. Arkwright inquires in query 56893, page 375) are, most probably, physically connected, as they have very nearly the same large proper motion; but no signs of binarity have as yet appeared. Mr. Wilson seems to consider that the path described is hyperbolic; but if we except one or two of the older observations, deduced from differences of R.A. and Decl., there has hitherto been little or no deviation from a straight line. It is difficult to say how small stars could be seen with any given aperture in the daytime, as that depends so much on the transparency of the atmosphere at the time, and the expression "daytime" is rather vague. Burnham has seen the fifth and six stars of the Trapezium of θ Orionis seven minutes before sunrise with 6in. aperture, and the fifth has been seen in bright sunlight with 15in. γ Leonis has been measured in bright sunlight with 3¾in. only, and the close *comites* of ι Orionis and ζ Orionis with 5in., and ε Boötis and α Herculis have been seen double with the same aperture; while Dawes has measured δ Cygni and ζ Herculis at noonday, with a little over 6in. of aperture. The period of the shortest pair known to me—viz., δ Equulei, is about 10·8 years.

June 30th. **H. Sadler.**

---

## ASTRONOMICAL-DOUBLE STARS.

[24439.]—Since I last wrote I have not been very much favoured with good astronomical weather. Hot, sultry days, followed by cool nights, windy, stormy, and cloudy atmosphere, are not helpful for nice, delicate work. I have, however, when relatively best, obtained a few results, which I beg Mr. Sadler kindly to examine and report.

ζ Boötis. P.A. 295° ±, in contact, power 180, split with a black line between discs; p. 208 and 370.

η Coronæ. 175° ±, somewhat easier than ζ Boötis.

Gled. 435. 110°, preceded by a star about 1′.

ζ Herculis. 90° ±, split with a black line beween discs, with 3½in. side aperture; p. 208.

Gled. 487. 330° ±.

Gled. 488. 310° ±.

Gled. 510. 50° ±, mean of three observations, but doubtful, as the star is excessively close.

Gled. 522. 215°, separated by small disc, p. 550.

Gled. 525. 150°, somewhat closer than 522.

Gled. 527. A.B. 80° C., 310° easy.

Gled. 530. 165°, divided with black line between discs, p. 370.

Gled. 536. 10°, this star looks closer than β, 0·55″ at present.

Gled. 566. 10°, preceded a little S. by a 10 mag. star, 3′ ± distant.

Gled. 572. 129°, faint.

Gled. 474. In his letter (24369) Mr. Sadler gives Sch.'s angle 7·5° : 0·33″ : 1882·47, and adds that this star is now wider. I have looked about six or seven times at this object; but I have not been able to see any elongation in that direction. It is a difficult object: to me more difficult at present than γ Coronæ. I have obtained a doubtful elongation about 130″; though on June 27, 1884, I wrote in my book, "A much more satisfactory view of its duplicity," p. 370. I should like to know if any competent observer has observed it this year, and with what results. Does Mr. Sadler think that the angle given by Sch. agrees with what is known of the orbit of this star?

γ Coronæ. Mean of six observations ranging between 140° to 125°, 135°.

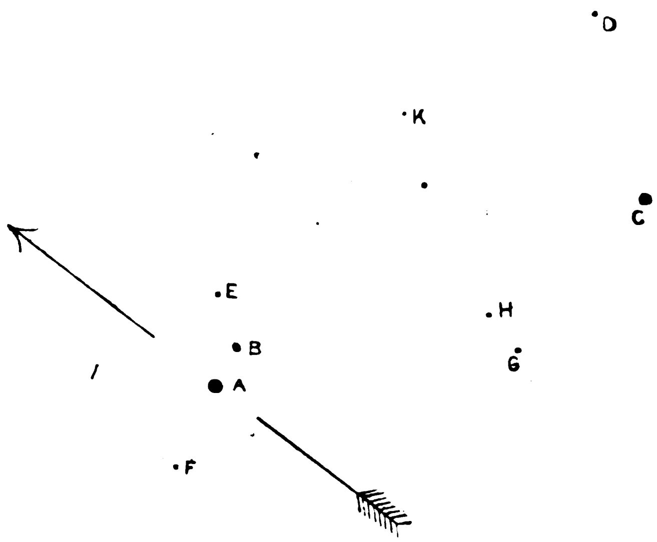
Will Mr. Sadler look at XVh. 32m. + 36° 5′? I found about that place a double, which is not on any list I have, P. 260° ± mag. 6, 7·5. I believe the distance is under 1″. I found it on July 1st with p. 180; but afterwards, with inferior air, it required 208 to be seen at all. The star is S. of ζ Coronæ, and is shown on Bode's Atlas, as given by Flammarion in his "Astronomie."

**C. M. Gaudibert.**

---

## DOUBLE STARS—53 OPHIUCHI.

[24440.]—On seeing Mr. Gemmill's note on this pair (letter 24390, page 364), I looked it up on Friday last with the following result:—The night was not good for the detection of faint stars owing to bright moonlight; but six more were found in the space shown by Mr. Gemmill, which are lettered according to magnitude in the accompanying diagram. The principal pair, A B, was rated at about 5·9 – 7·7 of Σ.'s scale—colours yellowish white and light blue; and two small *comites* were found N., a little *f.* + *s.p.* A B at about 75″ ±, rated at 11·5 ± of H. There is a minute pair (almost an exact miniature of 53 as regards distance) midway between A B and C, and another, rather wider and very much fainter, between B and D. The 8th mag. star C is orange, and decidedly larger than B, while there is a full 1½ mag. between C and D. The latter is very small, more like 10th mag. I do not find the two stars near 53 in any list I possess, but they are scarcely close enough to be reckoned *comites* in the strict sense of the term.



I have noted a similar discrepancy in the colour of the *comes* to 5 Serpentis, as given in "Celestial Objects." There it is called "pale grey"; but I have noted it on three occasions as reddish violet, very similar to the companions of δ Geminorum and η Cassiopeiæ. **K. J. Tarrant.**

Letchford House, Pinner, June 29th.

---

## 70 OPHIUCHI.

[24441.]—The double star 70 Ophiuchi is one of the most remarkable binaries in the heavens. Although the companion has more than completed one revolution round its primary since the time of its discovery; yet no single orbit out of the dozen which have been calculated will satisfy both the modern and the ancient measures. Mädler, more than forty years ago, despairing of reconciling the conflicting observations, suggested that either "die Bewegung in diesem Binarsystem erfolgt nicht nach dem *Newton*schen Gesetz," or else, "die Mittelpunkte der Figuren, welche die beiden Sterne für uns bilden, sind nicht die Schwerpunkte der Massen." Jacob came to the latter conclusion, considering that the smaller star described a secondary ellipse with a period of 26 years; but if this be the case, observation has, as yet, shown no trace of the disturbing object. Two of the latest series of elements, and those which best satisfy previous observations, are those of Dr. Schur and M. Tisserand, published in 1868 and 1876. From these, I find the following places of B for the present time:—

| | |
|---|---|
| Schur's orbit | 53·3° : 2·69″. |
| Tisserand's orbit | 49·0° : 2·50″. |

I believe, from a recent observation, that Schur's angle is at least 20° too large, and the distance certainly half a second too great, if not more. Krüger found for the parallax of this object 0·162″, giving a distance one million two hundred and seventy-two thousand times greater than the mean distance of the earth from the sun, and he deduced a value for the combined mass of the two components 3·1 greater than that of the sun, the mean distance of the companion from its primary being equal to that of the planet Neptune. There is a remarkable similarity between the binary stars 70 Ophiuchi and η Cassiopeiæ. In both the primaries are yellow, and the companions purple; the proper motions are almost precisely similar in amount and are very large, that of η Cass. being 119″ per century, and that of 70 Oph. 113″, while O. Σ. deduced a parallax of 0·154″ (with a probable error of 0·045″) for η Cassiopeiæ, giving a distance of one million three hundred and forty thousand solar distances. There is a wide discrepancy in even the latest elements of η Cassiopeiæ, but with Grüber's orbit (period 195¼ years) the mass of the system is 4·6 times that of the sun, with Doberck's (period 222½ years) 5·2 times, with Coit's (period 167¼ years), 6·4 times, and with L. Struve's (period 150 years) 8·3 times the solar mass, with a mean distance nearly twice that of Neptune. In the English Mechanic for July 14th, 1882, I drew attention to a very remarkable case of proper motion in a distant companion to 70 Oph., and this case was referred to about two months afterwards in *Nature*. The small star in question has apparently an actual proper motion of 1·28″ per annum, larger than that of 70 Oph. itself, and far larger than any hitherto known to belong to so faint a single star; for it is probably not much brighter than 16 mag. in Herschel's scale. Flammarion attributes a slight proper motion, on, I think, insufficient grounds, to the Herchelian companion of Aldebaran; and also a large p.m. to a small star between 36 Oph. and 30 Scorpii, from a comparison of a diagram of Smyth's and his own, which a rather more extended acquaintance with the observations of Smyth would probably have caused him to reject. The place of the small star near 70 Oph. was, in 1878 8, 197·0° : 71·30″, according to the measures of Prof. Hall at Washington. Will any reader determine its present position? A small nine mag. star (W. B. [1] XVII. 305) less than 5° S.W. of 70, has a p.m. of 0 67″ annually, according to the Glasgow observations.

July 1. **H. Sadler.**

P.S.—I notice that Mr. Franks made the colours of both components of 70 Oph. yellow in 1876. I should be glad if he would mention the date of his observation. De. gives the colours yellow, rose, on four nights in that year.

---

## PEARSON'S METHOD OF COMPUTING ECLIPSES AND OCCULTATIONS.

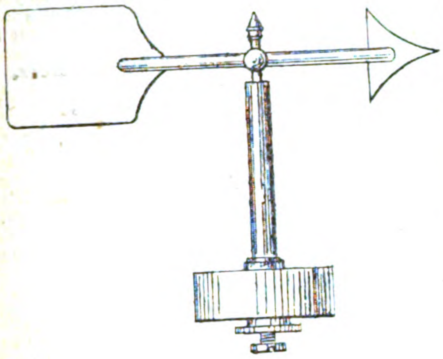
[24442.]—Referring to letter 24340, p. 322, Mr. Pearson does not seem to understand my way of obtaining the times of beginning and ending of occultations and eclipses by his partially-graphic method. I do *not* again divide the *ellipse* into hours and minutes, but the *moon's path only*. In making these computations I first complete the diagram in the usual way; then, letting the local mean standard, or sidereal time of geocentric conjunction fall at the meridian, I again divide the moon's path into hours and minutes of the same scale as before. This can be done in half a minute, and exhibits accurately and at once the local mean, standard, or sidereal times of beginning, nearest approach of centres, and ending. Mr. Pearson's rule is "Subtract the hour-angle at conjunction from the hour angle at the beginning (or vice versâ), and if the remainder be positive, add it to the local mean time of conjunction; if negative, subtract it. Similar operations are required to show the times of nearest approach of centres and ending."

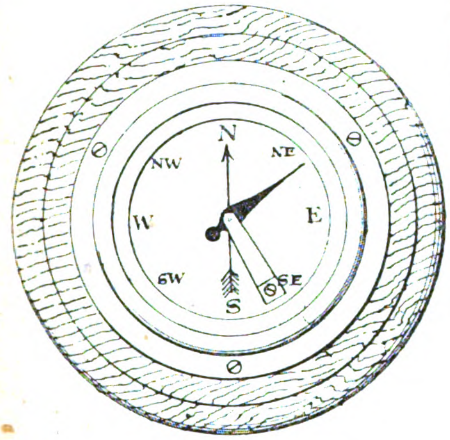
**Chas. L. Woodside.**

Boston, Mass.

### ELECTRICAL WEATHER VANE.

[24443.]—THE subjoined sketch shows a form of electrical weather vane devised and patented by me. The vane can be attached to any wall or ridge piece, and the receiver may be placed any distance from it. The arrangement of the latter permits of one, or more, being coupled-up to an existing vane, and as the current sent into it is only of momentary duration, it can be worked from any ordinary battery used for supplying bells or for other purposes. The needle used for indicating is nearly dead-beat, and accurately follows the swaying of the vane. One of these has been in constant use for six months without a hitch of any kind, and there is a complete vane and indicator at Stand No. 1378, Inventions Exhibition.





**F. M. Rogers.**

### ELSON'S FLASHING LANTERN AND INSTANTANEOUS CAMERA SHUTTERS.

[24444.]—As I see by the discussion going on in the pages of the "E. M." that some of your correspondents cannot get their so-called instantaneous shutters of their cameras to work satisfactorily, and as, doubtless, the rebound or recoil of the shutters, after springing home, is the cause of all their perplexity, allow me to offer the following, in the hope it may furnish a hint to those ingenious ones who care to think the matter out for themselves. On my constructing a double-shutter flashing lantern for signalling in the Morse on board ship, I found the one great fault which interfered with the rapid working of most flashing lanterns was in mine, and that was, when the two shutters (which open out across the front of the lantern) sprang together, they rebounded or vibrated for some little time before the light from the lamp was completely shut off, thus necessarily causing annoyance and delay in signalling, the symbols not being properly read unless a deal of valuable time and patience were lost by signalling slowly. So, to obviate this serious drawback, I constructed two hollow shutters of thin wood, so as to allow of a flattened, half-ounce round bullet having free play to roll from side to side of the narrow space inside each shutter, with the result, as I anticipated, that the shutters or screens now come together with a sharp, dead bang, as the (as I name them) leaden resonators inside them take up the recoil, and will back over the allotted space of about an inch or more. Now the light seems cut off clean, like a sharp knife cut of a rope, instead of, as before, when the shutting off of the light was as if the rope was torn or rent asunder with fagged-out ends.

The lamp has been pronounced to be perfection by the Sergeant Instructor at our headquarters. I inclose a drawing of it both open and shut, in the hope you will make it public for the benefit of our readers. Two hollow balls thrown by the same hand, the one containing another smaller ball free to move inside it, will not both reach the same distance, the momentum of the latter being expended or destroyed much soooner than the one containing nothing.

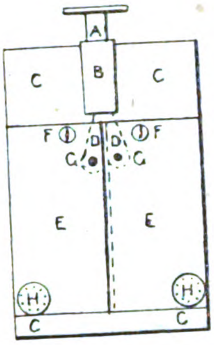


Fig. 1 shows the shutters closed and overlapping each other by the distance between dotted and plain lines running down the centre. A the key or plug surrounded by a spiral spring inclosed in the case B. The key is now pressed up by the spring, and the shutters are also kept closed by it. B the spring case—a hollowed-out piece of wood fixed to front of lantern-case C C, and overhanging the shutters E E, containing spiral spring and key plug A, which it encircles. C C C C front of lantern case. D D a pair of small flattened metal arms working in a notch on lower end of the key or plug A, and connected to the shutters E E at G G. E E the two hollow shutters working on screws F F. F F two screws as pivots for shutters E E to work on. G G two pins for the connecting arms D D. H H two flattened bullets as resonators, in the position they take up on the shutters striking together.

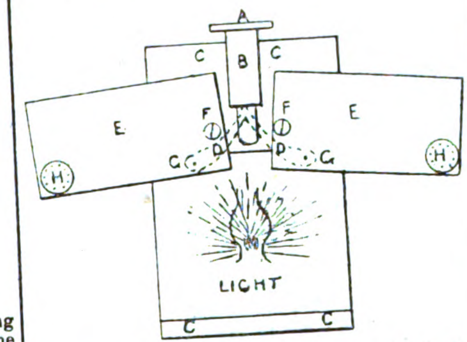

Fig. 2 shows the lamp open, with the leaden weights H H in the position they will occupy before they are sent rolling to the other side, as the shutters bang together when the thumb pressure on the top of A is released. The two metal arms D D are partially hidden between the two parts of the shutters to which they are attached by the pins G G. They are seen as dotted lines where they enter the shutters to their pins G G.

I trust the above may find a place in the pages of "Ours," of which I am the happy possessor of twelve back volumes, all bound,

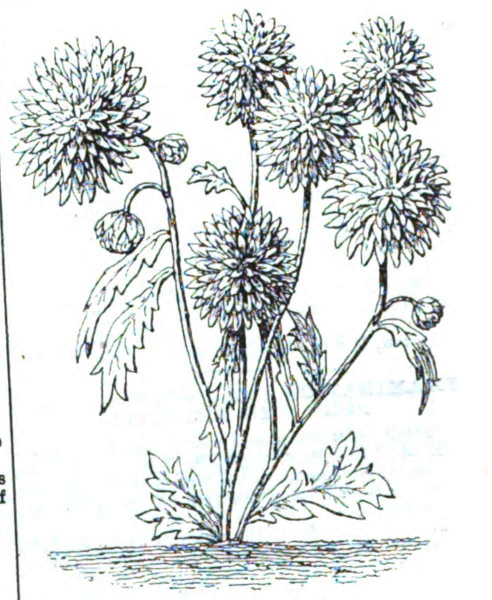
### THE NEW TIME.

[24445.]—THE adoption of the new time seems to be as far from realisation as ever, although a considerable period has now elapsed since the Washington Conference—enough, one would imagine, to show whether it is likely to find favour with the world at large. At present it must be a patent fact to every one that the consensus of opinion is decidedly adverse to it. Nor does this opposition proceed so much from the general public, who are, I fear, supremely indifferent to the question, as from a quarter where it might least be expected—from astronomers themselves. And why should they sacrifice the old 24-hour reckoning (from noon to noon), which is everywhere understood and recognised, not only by astronomers, but by seafaring men generally, in order to meet the convenience of the outside public, who really do not care a straw about it? If the public want a "universal" time, let them agitate for it; it would then be quite time enough for astronomers to consider how far they should subordinate their own convenience in adopting it. This, to my mind, is the only real argument in favour of the new system—its universal adoption; but, like many other Utopian ideas, it is better suited to the coming Millennium. As far as the abstract question of 24 hours noon to noon *v.* 24 hours midnight to midnight concerns the astronomer solely, independent of any public consideration whatever, there can be, surely, but little room for doubt as to which suits him the best. In spite of what our friend, "F.R.A.S.," says (p. 346, letter 24365) as to a solar eclipse beginning before noon and ending after it, as a difficulty with the old (*Nautical Almanac*) reckoning, it seems to me to be rather an argument in its favour, inasmuch as for every single observation of a solar eclipse made in the daytime, there are thousands of others made only at night. Although it is true that our own Astronomer-Royal has adopted the new reckoning, I am not aware that any other national observatory has seen fit to follow the recommendation of the Washington Meridian Conference. Speaking from personal experience, I have found the new system an unmitigated nuisance; breaking up observations in the middle of a night's work just at the tick of the clock, and if very deeply absorbed at the telescope, I have probably forgotten all about midnight being the precise time at which I ought, literally, to turn over a new leaf for another day's work. So, very soon after commencing to work with the new reckoning, I abandoned it again for the older system, which is in every way far more convenient and familiar. As a dutiful member of the L A.S., I had instructed the members of the Planetary section to use the new time, in accordance with the resolution passed at the December meeting of that society; but, at the same time, I own that I ignored it in my own practical work, and several of the members all along objected to the change. However, in the future, I intend to leave the new time reckoning severely alone, both in public and private. When the new system *is* universally adopted, I will, perhaps, change my mind; but until that uncertain epoch I am conservative enough to hold fast by the time-honoured reckoning from noon to noon, as amply sufficient for all the purposes of an observer.

**W. S. Franks.**

### DOUBLE CORN MARIGOLD.

[24446.]—As many of your readers, like myself, care for other things besides mechanics, I send you a rough sketch of what I believe to be a very rare variety of the corn marigold, which grows here in large quantities. The specimen is quite double; it became rather withered before I sketched it. I intended keeping the plant alive; but finding that it is only an annual here, pressed it. I also inclose specimens of the common sort and a light marigold.



**E. R. Dale, F.S.Sc. Lond.**

### COLLIERY EXPLOSIONS.

[24447.]—THE recurrence of these disasters follows the well-known old rule, a fallen barometer, a risen thermometer, an unusual escape of gas, of course, and funerals for 200 persons; and so it goes on.

Now, the barometer may have fallen ½in. in 48 hours, thus lessening atmospheric pressure 35lb. on the square foot, while the ventilation by suction of fan or furnace may have further reduced that pressure by another 35lb. on the square foot.

A ton of hewn coal is capable of giving off 10,350 cubic feet of carburetted hydrogen, which when mixed with nine times its volume of air makes 93,150 cubic feet of most explosive "fire-damp"; but a blower is known to be under pressure of 30 atmospheres, and, therefore, we may arrive at an idea of what quantity of gas one ton of coal while under pressure in the strata might produce. Thus 10,350 cubic feet of a hewn ton of coal multiplied by 30 atmospheres = 310,500 cubic feet of carburetted hydrogen, which, when mixed with nine volumes of air = 2,794,500 cubic feet of "fire-damp," which, if free and ignited, would blow up miles of workings, headings, and roads.

Now, those figures are given in order to convey some idea of the perilous nature of trifling with colliery ventilation.

There is no other means of real prevention than that of abolishing the system of ventilation by the suction of fan or furnace, and introducing instead air under pressure up to the face of the coal, by which means the atmospheric pressure may be maintained to a proper standard. For instance, every 1-10in. fall 7lb. per square foot must be supplied to meet the deficiency.

I must maintain that helping to bring about a "disaster" by easing pressure by artificial suction, when more pressure is the essential to safety, is most unwise, to use the mildest term. I hope some of your correspondents will discuss what I have said.

**J. D. Shakespear.**

25, Great George-street, S.W., July 6.

## COLLIERY WARNINGS.

[24448.]—The following dates are indicated as being periods in which a change of atmospheric pressure, combined with disturbances of the magnetic currents (earth currents) and seismic perturbations, may be expected to occur during the ensuing six months. Observation has put it beyond all doubt that an intimate connection exists between these disturbances and accumulations of gas in mines, therefore I name these dates as being *highly dangerous*, and the greatest care should be observed by miners.

Earth tremors also owe their origin to similar causes, and when they do take place will be found to occur approximately about the dates named.

This is a very interesting branch of science which has been unfortunately almost entirely overlooked by scientists. It is, however, worthy of the closest study, and although we can never expect to be able to prevent the outrush of gas in mines, there is no reason why we should not be able to indicate the periods when these occurrences have a tendency to take place, and thus be enabled to take precautions accordingly.

If colliery managers and viewers, or any other officials who have to do with mines, would keep a record of the dates on which accumulations of gas are observed to take place, and let me have a copy of such records, they would thereby greatly facilitate the investigations, and would found a basis upon which future calculations might be made.

The dates marked with an asterisk are periods of exceptional disturbance, and during these periods the utmost caution should be exercised in mines where gas is known to exist.

July 5, 6, 7*, 8, 22, 26; August 5, 6*, 15, 19, 28, 31; September 2, 4, 7, 15, 20*, 25, 26*, 29; October 2, 3*, 5*, 10*, 16, 20, 25, 27; November 6, 7*, 20, 22*; December 2, 3*, 4*, 5*, 18*, 19*, 28.

## EXAMINATION OF MINERALS BEFORE THE BLOWPIPE.

[24449.]—In accordance with Col. Ross's request, "E. M.," No. 1058, page 390, I would offer the following opinion as to the names of the minerals of which the blowpipe analyses on his system are there given:—

No. 1 appears from the analysis to be a white, "earthy" sulphate of aluminium, containing about 10 per cent. of potash. Dana ("System of Mineralogy," 1877, page 658) gives three such, under the head of "Hydrous Sulphates" (combined water not mentioned by Col. Ross, but no doubt existing in his mineral—viz., Aluminite, Alunite, and Löwigite). Of these the first contains no potash, and the last is stated to have a pale straw-yellow colour, and to be slightly subtranslucent. I therefore suppose Col. Ross's first mineral to be "alunite."

No. 2. "An alkaline aluminous silicate," containing traces of soda and lime, but chiefly silica with considerable alumina, and potash; "transparent, colourless, hard." This constitution points to feldspar of some kind or other, or, as Dana calls it, "orthoclase"; and at page 356 he gives a list of feldspars in which "the proportion of soda is much less than that of potash, from $\frac{1}{20}$th": nearly all of these contain traces of lime. I therefore suppose Col. Ross's No. 2 to be the variety of transparent crystalline feldspar (probably from St. Gothard, as he states it "is in a Freiberg Cabinet) called "Adularia."

No. 3. "A soft, greyish white, compact," aluminium silicate containing a little potash. Again, Col. Ross does not mention water, but it is evident that must be present to make a silicate of the hardest substance in the world next to diamond (corundum) "soft." I therefore turn to the "hydrous silicates of alumina" in Dana, or what he calls the "Margarophyllite section—i.e., having a "pearly" lustre. There I find, page 479, "Pinite," having a hardness of only 2·5 to 3·5; colour, greyish white; lustre feeble, waxy. In the percentage list of these there is a ratio of nearly 2 : 1 between the silica and alumina, and in the variety called "Agalmatolite" (of which the Chinese priests make their gods), a greater proportion of silica, no iron, magnesia, lime, or soda. I would suggest, therefore, that this mineral is "Agalmatolite."

No. 4. A hydrous silicate of lime with considerable proportion of potash, which "intumesces and froths up when held *per se* before the blowpipe." Looking in Dana, therefore, among the "Hydrous Silicates, Zeolite (from a Greek derivation signifying to boil up) section," I hit upon the zeolite *par excellence* called "Apophylite" (from another Greek word signifying to exfoliate or intumesce), and find—page 416—a list of apophyllites from various localities, which yielded (to different analysts) on an average 52 per cent. of silica, 25 of lime, 5 or 6 of potash, and 16 of water. But all of these, except one, contain about 1 per cent. of fluorine, which Col. Ross does not seem to have detected. Is No. 4 "Apophyllite"?

No. 5 must be "Cryolite," the well-kown fluoride of sodium and aluminium from Greenland, Arksut Fiord.

On the whole, I think Col. Ross would do well to pay more attention to the "lustre, hardness, and specific gravity" of his materials than he seems to do. A better description of these (he gives none at all of sp. gravities), combined with the results of his analysis, would very much facilitate and shorten the work of the student in hunting up names.

**Mineralogist.**

[24450.]—Now that Col. Ross (letter 24426) has opened his box, it is to be hoped that he will not close it till it becomes empty as that of Pandora. To those of your readers who possess a good work on mineralogy there will be but little difficulty in fixing the names of the Freiberg specimens: No. 1, I should call "potash-alum"; No. 2, a species of "orthoclase"; No. 3, I should call "kaolin."

Col. Ross's generalisations are admirable. Take a single instance in No. 1, where he determines the presence of sulphuric acid from "great effervescence" and unchanged pyrochrome. Though I write in haste, I sincerely hope that Col. Ross will continue his masterly analysis.

Gorton Brook. **Ex-Blacksmith.**

## PYROLOGY.

[24451.]—In order to show the *animus* against this subject still prevailing amongst many English chemists, I quote the following from the private and friendly letter of a well-known London chemist to myself. As he is not likely to see or hear of this publication, his letter will retain all the advantages of what lawyers call "a privileged communication"; and besides, it is only by making private insinuations and hypercriticisms public, that I can defend my system of Anhydrous Analysis from the many calumnies and slanders privately circulated about it, *a tergo*.

"I have just looked at pages 135 and 136 of your book, and it does not strike me as satisfactory. The logic is not complete, and this is serious in the matter of textbooks." (The reference is here made to the fact discovered by me, described in these pages, and admitted now by all German and other chemists who have gone into the matter, that quicklime, treated in pure boric acid (boron trioxide) before the blowpipe, combines with the latter to form anhydrous calcium borate, invariably containing 25 parts of lime and 75 parts of boron trioxide. Further, that if calcium hydrate be similarly treated, anhydrous calcium borate is formed as before, plus hydrated boric acid, the proportion of "water" agreeing almost to a decimal with the received chemical account of calcium hydrate).

"For junior students, for instance, it is not proved that *all* the lime is concentrated into the ball (calcium borate). Might not some of it be dispersed through the bead? Is not the rest of the bead altered in any way? When is all the superfluous water removed from the slaked lime? Is it not *assumed* that the lime has the formula CaO? and that the part of the bead which combines with the lime has the formula $B_2O_3$?"

Now, suppose I were to tell this chemist (a very clever man, and one who knows his work thoroughly): "When you tell us in your chemical textbooks that, by adding sufficient hydrochloric acid to a solution of silver nitrate, you obtain a precipitate of silver chloride in invariable proportions of chloride and of silver, your logic is not complete. You do not prove that *all* the silver of the solution is concentrated in the white precipitate of silver chloride; might not some of it remain dispersed through the nitrate solution? Is not the rest of the solution altered in any way? When is all the superfluous hydrogen removed from the hydrochloric acid? Is it not *assumed* that the silver has the formula Ag? and that the part which combines with it has the formula Cl?"

Were I to say this to any chemist, what do you suppose he would answer? I shall find out what this one replies to such queries, at all events, for I intend to send him this very letter.

**W. A. Ross.**

## WHAT IS "CREATION"?

[24452.]—"F.R.A.S.," in letter 24416, page 388, I think wrongly complains that I evade the difficulty he propounded as to albinos, &c., by referring these back to ancestral types in which they first appeared, as I say, by creation. He employs, however, a word which I never used, and which is liable to considerable misinterpretation, when he says, "suddenly created."

. The first real albino was probably, on the other hand, the result of slow, gradual, or selective creations, to which we have to this day not infrequent reversions.

"F.R.A.S.," however, ignores the more important question which I addressed to him. How, apart from creation, can he account for the first appearance of such abnormals? **H. B. F.**

## AUTOMATIC MUSICAL INSTRUMENTS.

[24453.]—The letter from Mr. Wenham to-day on the above subject contains a number of quite new ideas. I thought I knew all that could be done in this line; but his description is a revelation, at least to me. It is evidently a portable six-octave pianista. The pianista, I thought, was the best of this class of instrument; but it weighs about 1½cwt., its cost is about £30, and it has only 4½ octaves. I think Mr. Wenham should have sent his to the present Exhibition, as it would astonish a great number of musical folk. I do not, however, quite see how a vibrator can efficiently replace the suction bellows usually employed. Will he kindly explain if it is on the principle of the "Organo Piano," by Metzler and Co., and give us a sketch, as it doubtless is quite as interesting to many others as it is to me? I publish my address, and would be glad to hear from him. **Vulcanite.**

[24454.]—I have no recollection of being "frequently told that the organette is without levers"; but accepting the statement of "Gray's Inn" as correct, I can only say that those who told me so showed their ignorance of the construction of the instrument in question. I happen to possess a sketch of the mechanism sent me at the time by their original importer, from which it appears that there is a series of levers *below* the paper, which spring *upwards* through the perforations, and in so doing, open the pallets which lie immediately underneath them; but as this sketch is merely sufficient to show the principle, I have been desirous of getting Mr. G. Fryer to fulfil his promise, and send a working drawing. I presume "Gray's Inn" confuses the "organette" with the "orguinette," hence his blunder in attempting to correct me. Mr. Wenham's outline description of his pianista interested me greatly, as he has succeeded in applying a principle which I failed to "lick into shape," as applied to a wind instrument. The essential difficulty is to hold down the note without getting any tremulous sound, and yet be able when necessary to obtain a rapid repetition of it. This difficulty does not arise in Mr. Wenham's arrangements as there is no holding down required. It is just the same principle as that of the Jacquard loom, where the perforated cards push aside the hooked wires, and so prevent them being lifted by the bars of the lifting frame.

I worked out the idea in several ways; the best seemed to be to give the plungers a constant tendency to hold down the notes, but to retain them in a raised position by a kind of rapid "pick-up," something like the action of a friction-break; but the detail was not satisfactory. I am surprised at the small size of aperture in the orchestrone. I made many experiments on this point, and found a round hole ¼in. diameter was practically the smallest through which a reed (say the lowest note of an English concertina) would speak clearly without an excessive wind-pressure. On the other hand, in trials with organ-pipes I found a very much smaller channel could be used than that usually adopted.

Would Mr. Wenham kindly say how he gives the rapid motion to his "finger-piece" or "vibrator?"—whether by gearing or endless band.

**A. S. L.**

## CRANK AXLES.

[24455.]—It seems to me that the numerous contributors to this discussion overlook a fact which must largely conduce to the failure of axles generally, whether cranked or plain, and whether of engines, coaches, or trucks—viz., that each member of each pair of wheels is in rigid connection with its fellow.

As a consequence, torsional strain of a severe character is put on the axle whenever a curve is traversed. That such a practice should be continued as regards the engines one can understand, as the difficulty of providing each driver with an axle distinct from the one opposite to it would be great, seeing that a central support for the inner bearings would be needed, and in order to get room for this outside cylinders might have to be used.

But that such a barbarous and unmechanical plan should be employed for coaches where no such difficulty exists seems well-nigh incomprehensible. Possibly lubrication, or removal and replacement, may be more readily effected; but surely such matters are far outweighed by anything that tends to make the axle safer and more lasting.

July 5. **B. B.**

## THE CASSEGRAIN.

[24456.]—At last we are getting what (in common with Mr. Wassell, and no doubt many others) I have so long desired to see, and there is no doubt the subject will be handled in the same masterly manner that the achromatic telescope has been handled by the same contributor.

May I, however, ask him if it is not possible to give a formula to determine directly the distance A B (or A D) when the foci of the two mirrors (for parallel rays) and their distance apart are known. In testing old instruments the position of the point A is not known, nor is it easily discoverable by trial.

There are several curious points suggested by the formula; for instance, it would seem that in a Gregorian, if *both* mirrors were parabolas, the points C and E would coincide, and A would be thrown to an infinite distance, supposing the mirrors to be so placed as to be free from aberration. Is this really the case? **A. S. L.**

## 100 TO THE INCH ON SMALL TELESCOPES.

[24457.]—Mr. Franks states, on p. 368 of the Mechanic for 26th June, that "very small telescopes—say, of 2in. aperture and under, will not bear a power of 100 to the inch." I beg to state that I have a 2¼in., on which I frequently use an eyepiece magnifying more than 100 to the inch on lunar craters, Saturn's ring, and close double stars with advantage when the objects are at a fair altitude. I am able to speak positively on this point, as the eyepiece has been carefully tested by the dynamometer. I also know of two smaller instruments, one of 2in., and one of $1\frac{6}{10}$in. aperture, each of which bear 100 to the inch.

**An F.R.A.S.**

[24458.]—Is Mr. Franks, in letter 24409, p. 368, quite sure he has not fallen into an error?

It is with great diffidence I make this suggestion, as Mr. Franks's opinions have the approval of our valued friend, "F.R.A.S.," in letter 24416, p. 388, and an opinion endorsed by such authority seems beyond question.

Still, I have always understood that circles vary in area as the squares of their diameters.

In which case, taking Mr. Franks's illustration, it is quiet evident that a 2in. o.g. has only one quarter the light of a 4in., and so, that the images may have the same intensity of illumination (granting equal perfection of figure), given the extreme limit of power the 4in. would bear, the 2in. would bear exactly one-half the magnifying.

I do not for a moment suggest that the 100 to the inch formula is correct: my own experience contradicts it. I find that any higher power than 450 on a 6½ silver-on-glass reflector gives an unpleasantly dull image.

But I do say (neglecting any small difference of absorption caused by varying thicknesses of objectives) that with equal perfection of figure and polish, given the highest power a 1in. glass will bear, a 2in. will bear twice the power, 3in. thrice, and so on. On reconsideration, I think Mr. Franks will see this.

Some time ago I asked if any brother reader, could give me his experience of the utility of a paraffin-coated vessel for silvering specula, but have received no reply. Will any one who has tried it kindly give the result?

Ilkley, July 3. **Allan. E. Kershaw.**

[24459.]—A correspondent has written to me respecting my letter on the above subject (24409, p. 368), and requesting that my reply may be given in these columns. His statement is to this effect: "Suppose the object taken be Jupiter, and the 4in. aperture be charged with a power of 400 diameters, the 2in. with 200, and the 8in. with 800. Then, although the 2in., with power of 200, has only a quarter of the light of the 4in., yet, as the half power duly magnifies Jupiter to a quarter of the *superficial* size, the brightness of the two telescopic images must be equal. Similarly the 8in., with double power, spreads the light over four times the area, and the image will be no brighter than in the 4in." This is perfectly true, no doubt; but, as a power of 100 to the inch is quite out of the question for planetary work, I think the case is somewhat hypothetical. As Chauvenet says in his "Spherical and Practical Astronomy" (Vol. II. p. 15): "Let us suppose two telescopes, the object-glasses of which are of different diameters, to have the same magnifying power. Then the brightness of the two images formed will be proportional to the quantity of light which falls on the surface of the two objectives respectively; but these surfaces are proportional to the squares of the diameters of the objectives, and hence the brightness of the images is proportional to the squares of these diameters. On the other hand, let us suppose two telescopes, with object-glasses of equal diameters, to have different magnifying powers; then one and the same quantity of light is distributed over the larger and over the smaller image, and, consequently, in this case the brightness of the image is inversely proportional to the square of the magnifying powers." My remarks were intended as applying to *stars*; but, for objects possessing a sensible magnitude, they require modification. Suppose, then, for the sake of argument, that we assign 50 to the inch as a maximum limit for planetary magnification, putting 100 on the 2in. and 200 on the 4in. o.g. The brightness of the two images should be equal. Now I know that a 4in. o.g., if good, will give a brilliant image of Jupiter with a power of 200; but I have never seen a 2in. yet that I should care to observe the planet with when charged with a power of 100. Two other considerations come in, as affecting this question, which somewhat complicate the result. One is the part played by the *objective* itself in defining power. Take a 2in. o.g., of, say, 30in. focus, and compare it with a 4in. of 60in. focus, stopped down to 2in. aperture, the magnifying powers being equivalent. Direct the two telescopes, side by side, upon Jupiter, and although, theoretically, the central 2in. of the larger glass admits slightly less light because of the greater thickness of its lenses, yet more detail will be seen with it than with the 2in. full aperture. Why should this be so? The other point is the difference in the *eyepiece* lenses, consequent upon the dissimilar focal lengths of the objectives. To obtain equivalent power, the shorter focus must have smaller and deeper curved lenses in the eyepiece; these will admit less light, partly from greater absorption with the increased thickness of glass, and partly from the greater loss of light by surface reflection from sharper curvatures—not to mention the increased errors of workmanship in minute lenses. Further, to carry the argument to its logical conclusion, could a power of 1,300 diameters be employed on a 26in. o.g. in viewing Jupiter? I fancy the result would be a fearful and wonderful illustration of what the atmosphere can do in setting optical theories at defiance! As a fitting sequel to what I have urged against inordinate magnification, permit me to quote Professor S. Newcomb's remarks in his "Popular Astronomy," pp. 142—145: "Still another cause which places a limit to the power of telescopes is diffraction. When the 'emergent pencil' is reduced below $\frac{1}{50}$in. in diameter—that is, when the magnifying power is greater than 50 for every inch of aperture of the object-glass, the outlines of every object observed become confused and indistinct, no matter how bright the illumination or how perfect the glass may be. The effect is the same as if we looked through a small pin-hole in a card, an experiment which any one may try. . . . The great foe to astronomical observation is one which people seldom take into account, namely, the atmosphere. The amount of this atmospheric disturbance varies greatly from night to night, but it is never entirely absent. If no continuous disturbance of the image could be seen with a power of 400, most astronomers would regard the night as a very good one. . . . If seeing depended entirely on magnifying power, we could not hope to gain much by further improvement of the telescope, unless we should mount our instrument in some place where there is less atmospheric disturbance than in the regions where observatories have hitherto been built." **W. S. Franks.**

[24460.]—Mr. W. S. Franks is, I think, not quite accurate in his statement in letter 24409, to the effect that a 2in. o g., power 200, has only a quarter and an 8in., power 800—four times the amount of light of a 4in., power 400, respectively. When the power is doubled you have only one-fourth of the light, and by doubling the aperture you have four times the light; therefore the amount of light in each of the three cases cited above will be identically the same.

I take this opportunity of thanking "A Fellow of the Royal Astronomical Society" for his kind reply. The thanks of all are due to "Montmartre" for his exertions with regard to Galilean binoculars. I do not believe that there would be an *appreciable* loss of light when a 2in. o.g., power 5, was increased to power 10, because the emergent pencil would be decreased from ·4in. to ·2in., and ·2in. is as large as any human life can take in. No light can be gained by having part of the emergent pencil falling on either your eyebrow or cheek-bone.

Last night, 28th June, 9 p.m. (atmosphere very clear and steady), I saw seagulls on an islet, distant 11½ statute miles, with 1⅛ Dallmeyer, power 15, and 1⅝ Dallmeyer, power 10, and just perceived them, knowing where to look for them, with 1¼ Dallmeyer, power 8¾. **Edward M. Nelson.**

Shetland, June 29th.

## HIGH-POWER OPERA AND FIELD GLASSES.

[24461.]—Referring to the last paragraph of "Montmartre's" letter (24393), I hope that correspondent will do what he can to get the new French high-power glasses within reach of those of your readers who require them. The difference in price between them and the so-called English glasses should alone secure a good sale for the former. By the way, is it not a fact that all opera and field glasses are made in France? If so, why so much difference in price?

I should like to draw the attention of "Montmartre" to the fact that whereas the 7-power glass is priced at 82s. (or in brass and morocco at the reasonable figure of 39s.) the 10-power glass costs the large sum of 181s. The extra power seems too costly at the price. Why should the size and price of this glass be so largely in excess of the 7-power glass? Could not your correspondent get the makers to more nearly approach in size and price the latter glass, but with the 10-power?

**E. C. J.**

[24462.]—It is almost incredible that a person having any knowledge whatever of optics should persist in the delusion that increase of power in an object-glass of given size can be obtained without any sacrifice of light or field. I appeal to "F. R. A. S.," who, perhaps, will be kind enough to settle this point, and to give your readers his valuable opinion as to what power is most suitable for opera glasses—not to convince "Montmartre," but perchance to prevent the uniniated from spending their money foolishly. What can "Montmarte" mean by this? "By night it (a Ross telescope) could show nothing at all, whilst the 10-power showed everything perfectly, *by day and night equally well.*" The proper place for the French glass, which shows everything as well by night as by day, is at the Inventions Exhibition in a case with the Irish gun, which kills as well round the corner as straight in front of it. I have no pecuniary interest in any firm of opticians, English or foreign, but as I believe the former to be unrivalled in the quality of their goods and moderate in their prices (quality being considered), I have but little patience with the attempts sometimes made to puff foreign glasses to the detriment of our own manufacturers, who are prepared to give us better value for our money than can be got elsewhere.

**Experience.**

## THE MICRO-OBJECTIVE.—V.

[24463.]—This paper is to fulfil the promise made at the end of my last, p. 327.

In planning an o.g. it is well to keep to as few curves as possible. For a 1in. of good quality, grind a plano-convex flint of ⅜in. radius, ditto of ¾in. radius; double convex crown of equal curves to match the flints. Cement the two pairs with Canada balsam, and mount them at the right distance apart to correct the spherical aberration.

For a ½in., grind a plano-convex crown lens of ⅕in. radius and at least ⅛in. thick. It may be $\frac{3}{10}$in. diameter. This is the "front" of a single lens.

Now grind a plano-convex flint of ⅗in. radius, and a double convex to match; these may be $\frac{4}{10}$in. diameter, but as thin as possible; when cemented these are our "middle"—an achromatic double.

To complete the o.g. there must be a third combination, of three lenses.

A bi-concave flint, of ½in. radius, has cemented into it a plano-convex crown on one side and a double convex on the other, making a triple, over-corrected combination; all curves of the same radius. This is the "back" diam., little, if any, more than the middle.

Mount these so that the back and middle are almost in contact; then let the front be placed sufficiently distant from the middle to be correct for spherical aberration, all plane surfaces to be towards the object.

The curves given for the ½in. I have proven good for a ⅙in. and a ⅛in., as well as the ½in., so that no one need hesitate to spend their time upon the *apparently* great task of perfecting 12 surfaces in glass on the supposition that it is only an experiment, or speculation, after all.

I will, however, give here data for a ¼in., of so precise a character that only the more advanced amateur will be able to undertake it; but there may be some who will make use of it.

Beginning, as before, with the single front:—Radius $\frac{1}{20}$, diameter ·093, thickness ·057, density of glass 2·437.

Middle:—Front surface, concave to ⅜ radius; second surface, also curve of bi-convex crown in contact with it, ·1165 radius; next surface the same radius; density of the flint glass, 3·686; crown, same as front; diameter, ·138.

Back:—A triple; first surface, crown glass plane; radius of second surface, convex, also both curves of flint lens concave, ·220; bi-convex crown lens to fit the concave on one side; on the other a curve of ·156 radius; density of flint, 3·630; crown same as before; diameter of the combination, ·173; ang. aper., 130°.

This specification was in "Ours" some 12 months ago, and is hereby acknowledged to be a copy, in case the owner takes me to task for it. I think the owner was Mr. Wenham; the writer certainly was.

To return now to my own work, it will be noticed that I say nothing respecting the density of the glass used. That is a refinement which I have found it possible to avoid, as also the third decimal figure in the radii, for the distance at which the lenses are placed, the one from the other, is so very powerfully corrective a factor that the above very precise working is needed in the o.g.'s of the highest angular aperture only.

If a combination be found under-corrected for spherical errors, or correct only when the front is so far from the middle that no space remains for the object—that is, no working distance is left—the plane surface of the middle may be made concave with good effect. The radius of curvature used should be four, five, or six times the focal length of the o.g.

Testing:—Hold an ordinary lens of an inch focus three or four inches from a strip of card having parallel edges and about an inch wide. In the lens will be seen an image of the card, and, if the distance of the lens from the card be such that the image nearly fills the lens, the two edges of the card will not be straight, but barrel shaped—double convex. Now use a negative eyepiece in the same way, and the edges of the image will appear *nearly* parallel; the field lens should be towards eye in this experiment, and the eye cap removed.

In an achromatic o.g., used on the same plan, the edges of the image should be *quite* straight and parallel; it may then be tested on fly wings, podura scales, micrometer ruling, or mercury globule, as required. The last two are fine tests, which I will explain if required, but this paper will be long enough without.

The card strip test is only an index to the condition of the lens as far as spherical error is concerned, and is of no other use. In using it, don't *spy through* the lens with the eye close, but simply look *at it*. If a straight, smooth edged bit of thin metal be held in the focus of the lens, and the eye be placed as close as possible to the "back," light coming from, say, the right, and the edge of the metal plate passed as far as possible to the left, a rough estimate may be formed of the colour correction of the combination; more rigid inquiry may then be made as before on scales, &c.

To "Optical," p. 390.—I would say that the difficulty he finds often arises from washing the emery too finely, for by over-doing the emery washing—that is, the "optical mud"—all the emery settles in the 5 and 10 minute washings, and the so-called 30-minute emery is nothing but glass dust. This dust makes plenty of cobweb lines on the lens being ground, but cannot properly cut it. I never use any washings but what have a good brown tint, and they don't usually take more than five minutes to settle, or ten at most.

**Rob. Crus.**

### THE RIGHT-ANGLED PRISM INSTEAD OF A PLANE MIRROR IN THE MICROSCOPE.

[24464.]—In your issue of January 30 last, Mr. Nelson replied to a query (55722) thus: "Right-angled prisms are used in telescopes for the purpose of economising every particle of light. In the microscope, however, even with a ½in. wick, there is more light than one knows what to do with." With great deference to Mr. Nelson, it is not the *quantity* of the light (which can easily be controlled) but the *quality* which renders the prism, I believe, preferable. For a long time I have always used the prism whenever delicate management of the light was required. I do not exactly see why it should be so, but I believe the reflected rays from the posterior silvered surface and from the front unsilvered surface prevent the lights from being brought accurately to focus on the object on the stage. This belief is founded on the following interesting experiment, for the idea of which I am indebted to one of Dr. Royston Pigott's papers which I read some years ago.

In the winter time, when the leaves are off the trees, I placed my microscope with a prism and achromatic condenser at an open window opposite an old oak, about 250ft. distant. With a little management, the reduced image of the oak formed at the focus of the condenser was viewed by a ⅛th objective. With suitable apertures in the diaphragm of the condenser, and in an iris diaphragm fitted on to the lower portion of the condenser between it and the prism, a most exquisite image of the tree was seen. The definition of this was charming, every little twig and incipient bud being distinctly visible. Then, nothing else being altered, a plane mirror was substituted for the prism. What a change! The larger branches were there indeed, but the slender twigs were involved in hopeless "fuzz," which no amount of manipulation could eliminate. The experiment was varied by forming the image of a net window curtain about three yards distant from the microscope. With the prism, the picture of the network and pattern was perfect, every detail being exquisitely shown. With the plane mirror, the image was very markedly inferior, thought less so than in the former experiment. My attention was first drawn to the prism by a kind friend and distinguished member of the Microscopical Society, who has employed one for years.

**George Hunt.**

Alleyn Park, West Dulwich, July 4th.

### A NOVEL CLOCK—ALUMINIUM—HIGH POWERS FOR TELESCOPES AND FIELD GLASSES.

[24465.]—In answer to "A. H." (query 56491), a brass bowl will do very well, but it should not be too thick, else a strong magnet will be required. A pudding bowl would do also, but I prefer a china one for appearance and because it is so much thinner. If a brass bowl be chosen, the inside rim might be coated with wax, the figures made through the wax with a pointed instrument, leaving the metal bare, which can then be eaten into with nitric acid. But I would not eat the figures too deep, as the magnet on the fish might catch in them. I hope "A. H." will let me hear how he succeeds. I am obliged to the correspondents who have pointed out prior clocks of this kind. It is not easy to invent anything quite new in these days.

I may tell "Ex-garrison Gunner" (query 56949) that I spent my spare time during three years in trying to find a cheap method of extracting aluminium, but without success. There were some letters in the English Mechanic a year or two back, giving new methods which I tried unsuccessfully. I do not believe that there is any other commercial method of obtaining the metal than the old method of acting on the chloride or the native fluoride (kryolite) with sodium. I can give "Ex-G. G." full particulars of this method if he wishes. I will also suggest an experiment which I had no opportunity to try myself, but think would succeed. If alumina be fused with iron, part of the latter is oxidised at the expense of the oxygen in the alumina, and the two metals combine to form an alloy. As sulphuric acid does not act on aluminium it might be possible to dissolve the iron out. If this succeeded I should say that plates of the alloy might be used in galvanic batteries as the active metal, and thus the aluminium be produced for next to nothing. Anyhow, I make the idea a present to any one who cares to try it.

With reference to all the late letters on high powers for day telescopic use, I believe the fact to be that persons accustomed to telescopic work can use high ones, when ladies and non-scientific men care more for a bright view. I have used a 3in. refractor for years, both here and in the Channel Islands, for day work, and always employ a power of 55, which I find most suitable for reading the names of ships—a good test.

"Aqua" (query 56961) will, if I remember right the tales I read in my boyhoood, find a device of the kind he mentions referred to in that wonderful book "The Swiss Family Robinson," where the fortunate family of that name finds in the course of time everything it can possibly require. I have heard something also of a "water tricycle," but do not know how it worked.

Tynemouth. **Garrison Gunner.**

### AËRIAL NAVIGATION.

[24466.]—Can any of your readers assist me by the suggestion of some very light material suitable for the construction of aëro-fans? In the model of my aërial propeller, now at the Alexandra Park, Muswell Hill, in the Exhibition there at present being held under the auspices of the Aëronautical Society, I use oiled calico as the material for their construction, and this material does sufficiently well to show the conception of the apparatus, and also gives a fair idea of its probable power; but I am not satisfied that the best results are obtained from it, and wish to change the material for something of a lighter character. Oiled silk would probably be an improvement on the calico, but I should prefer something lighter even than that, if I can procure it. In fact, I desire to employ a material of as low a specific gravity as possible; my theory being that the lighter the propellers are, the greater propelling power they will possess.

To render my meaning plain, and to support my theory, I will suppose that a solid cube of some material of considerable specific gravity, such as iron, be at a state of rest, and another cube of similar size but of lesser weight, such as wood, be projected with moderate force against it. The result of the impact would be that the heavier cube would remain unmoved, while the lighter one would rebound by the blow, owing to the moving force of the lighter weight failing to overcome the inertia of the heavier; and it is exactly this condition of things that I desire to realise with my propellers. I do not anticipate being able to construct them of any material less ponderable than air; but the lighter the material is, the more nearly will the approach be to the desired condition, as the lighter they are the less will be the movement of the air, the greater resistance offered to their action, and consequently the more effective propulsion. No doubt the shape of a bird's wing is a factor in its power of flight; but it is probable that the material of which it is constructed is of equal importance with the shape. If the numerous plumelets of which a feather is composed were deprived of the more ponderable or quilly portion of their construction, it is probable that the feathery or downy portion that remained would be less ponderable than the air itself; and if so, the action of these comparatively imponderable propelling surfaces against the air would be similar to the action of the wooden cube against the iron one; owing to deficiency of gravity, their movement would fail to overcome the inertia of the air, and the resistance to their action would result in effective propulsion, and consequently flight. **Chas. Groombridge.**

### ELECTRICAL.

[24467.]—With a battery of a given number of cells the maximum current is obtained, as is well known, by such an arrangement as makes the internal resistance of the battery as nearly equal as possible to the external resistance with which the battery is to be used. Thus, if we have $n$ cells, and connect the battery so as to have $a$ cells in series, and $b$ cells abreast ($n = a\,b$), that is, so as to have a battery of $a$ cells each $b$ times as large as a single cell. The resistance of each of these large cells is $\frac{r}{b}$ when $r$ denotes the internal resistance of one cell, and if further, E denotes the electromotive force of each cell, and R the external resistance, the current (C) is

$$\frac{a\,\mathrm{E}}{a\,\frac{r}{b} + \mathrm{R}}$$

$$\text{or } \mathrm{C} = \frac{b\,a\,\mathrm{E}}{ar + b\mathrm{R}} = \frac{n\,\mathrm{E}}{ar + b\mathrm{R}}$$

Very few textbooks attempt to give any *proof* that C is a maximum when $a\,\frac{r}{b} = \mathrm{R}$. The following simple proof may, therefore, be interesting:—If $x$ and $y$ are two numbers whose product is constant, then $x + y$ is *least* when $x = y$. For, since

$$(x + y)^2 = x^2 + 2xy + y^2$$
$$\text{and } (x - y)^2 = x^2 - 2xy + y^2.$$
$$\therefore (x + y)^2 - (x - y)^2 = 4xy$$
$$\text{or } (x + y)^2 = 4xy + (x - y)^2$$

Now, since $xy$ is a constant, $4xy$ is also constant; and we see that $(x + y)^2$ is greater than a certain constant number by a quantity $[(x - y)^2]$, which is *least* just when $x = y$. $(x + y)^2$, and therefore, also $x + y$ is a maximum of $x = y$. Hence, in the formula

$$\mathrm{C} = \frac{n\,\mathrm{E}}{ar + b\mathrm{R}}$$

the condition of maximum current is that $ar = b\mathrm{R}$, or that $a\,\frac{r}{b} = \mathrm{R}$; or in words, the internal resistance of the battery must equal the external resistance. **X. N. X.**

### NEW TRAINS, &c.

[24468.]—Can some correspondent say whether the 8 p.m. from King's Cross is correctly timed in Bradshaw? It would seem that it runs from Newcastle to Edinburgh without the usual stop at Berwick, 123 miles in 2 hours 55 minutes. How do the engines manage about water? Do they pick it up, or are the N.E.R. tenders of such abnormal size as to carry all that is necessary. There have been some very great developments in speed lately, and increase in the number of trains running at high speed, and I think that, at present, the L. and N. W. are running the fastest. Their 12 noon to Rugby runs from Willesden there in 88 minutes, a distance of 78 miles, and just beating the Dutchman. Another improvement which has been gradually noticeable is the punctuality observed on the important lines. The G. N. R. and the M. R. always were praiseworthy in this respect, and now a train five minutes late is the utmost rarity on the G.W.R. and L.Y.R., on both of which lines I travel frequently. I can understand a driver on a long trip—say, from Rugby or Grantham—with a good head of steam, getting ahead of the time-table; but I always have wondered how, as on the G.N., they can in a two hours' run hit their time almost to a second.

Are there any engines on the L. and N.W. which run to Crewe and back on the same day? I have always understood that a run of 200 miles was looked upon by drivers as a full day's work. I have seen at the Inventions Exhibition a brake called by its inventor "The Gravity," an improvement, so the prospectus states, on the ordinary method of working the vacuum, in that the brake block is allowed to fall on the wheels by its weight, and no force is used save that which releases it. Is this anywhere in practical use?

**John T. Lawrence.**

### DYNAMO MACHINERY.

[24469.]—In his recent work on this suliject Prof. S. P. Thompson makes some calculations on the efficiency of large and small dynamos. In the experimental data the effects of two sets of wire coils are given, one pair of coils being double the linear dimensions of the other one, and the working effect of the larger coils is estimated as 32 to 1. I should like to know from some of your readers who are more advanced in the modern methods of mathematical determination, whether this is strictly correct, as in my view of the matter the proportion is 8 to ½, that is as 16 to 1:

For the larger coils have the effect 2 by 2 by 2 = 8, which is the cubic capacity of the coils and the distance from the neutral point of magnetic attraction will be twice that in the case of the small coils, hence 8 by two gives the mechanical pressure of 16, which is according to observed experiment, and the small coils by the same kind of calculation give the pressure 1; but the working effect in moving from the pressure 16 to zero, or the neutral point of magnetic attraction will be $\frac{16 + 0}{2} = 8$, which is the mean pressure for the large coils, and in the same way $\frac{1 + 0}{2} = \frac{1}{2}$, which is the mean pressure for the movement of the small coils to the neutral point of attraction; therefore the working power is as 8 to ½, and not 32 to 1, as estimated. The late Dr. Page made some calculations in regard to his axial engine coils similar to those of Prof. Thompson, but they were not evidenced by experiment.

In proportionate electromotive machines, so far as I have observed, for the same strength of current the effect is in proportion to the length of wire; but the very remarkable coincidence that copper conducts eight times better than iron, gives as a result that the maximum effect of electromotive engines is produced by winding solid iron cores for electro-magnets to *one quarter their diameter* instead of one half, as is the general rule for ordinary electro-magnets, and for the same reason the length of a round magnet should not exceed sixteen times its diameter.

**J. Sutcliffe.**

### LOGARITHMS.

[24470.]—Charles North (letter 24427) has almost answered himself. It would require logarithms of nine places at least to show the difference that he is in search of; he has used only seven-place logarithms.

**Dublinlensis.**

[24471.]—Why should Charles North expect a change not affecting the first seven figures of his $a^2$ to affect the seven-figure logarithm? His $b^2$ is but 121, which, by addition to his $a^2$ touches none of its first seven figures. Nor would it by subtraction, if the last three exceeded 121, which they do in more than seven cases out of eight. Or rather, it never would, if the seventh figure be rightly reckoned.

**E. L. G.**

**London Stereoscopic and Photographic Co.**—Elsewhere this week will be noticed the prospectus of the London Stereoscopic and Photographic Company, a firm so well-known as hardly to require mention at our hands. This business, which has hitherto been carried on as a private partnership, should still further develop as a limited company. It will be seen in the prospectus referred to that the average profits are taken over a period of twenty-three years, and that owing to the very large increase in the amateur photographic trade, the latter results are even still more satisfactory. Although to recommend our readers investing their moneys is usually somewhat out of our line, we can safely, in this instance, make the exception, and will only add that any one desiring to become a shareholder should apply at once, for we understand that more than half the capital was subscribed for immediately it was announced. In conclusion, we would draw the attention of those amateur photographers who are amongst our readers to the fact that 1,000 shares are to be reserved to them, and it is quite expected that owing to their co-operation the dividends will be considerably increased.

## REPLIES TO QUERIES.

⁂ *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[56031.] — **Reservoirs.** — Many thanks to "Glatton" for noticing my query. It is not "misworded"; but I will explain. I want to evaporate a large quantity of liquid, and it must be done at a temperature not exceeding 112deg. F. Of course, to do this it will be necessary to work at a pressure below that of the atmosphere—that is to say, in a partial vacuum. I propose to have a boiler similar to a Lancashire boiler, with two or more tubes, if required. No heat to be applied to the bottom of boiler, so as not to disturb the sediment that would take place; the sediment to be taken out at end of week. The liquid is not very dense. I suppose there would be about four bushels after about 140 hours work, the quantity of liquor being as much as would flow through a ¾in. pipe, with a fall of 5ft. The vapour or steam from the boiler would have to be led into a surface condenser, and a pump fitted to condenser to clear it of water and to keep a vacuum. As this water would be very soft, and much better for my purpose than fresh water, I should use it over again. The condenser could be put 15ft. or 20ft. above the boiler, and the pump as much below condenser. I should be glad if "Glatton," or any other readers of the "E.M." could give me some idea as to the size and construction of pump suitable for my job. There would be no air to contend with, except the little that would be contained in the liquid. As I think there would be a small quantity in it, I should like to get a vacuum of some 10lb. or 12lb. per square inch if possible, and what I wanted to know by my query was, what thickness of boiler-plate would be required in a boiler or reservoir to stand this outside pressure of from 10lb. to 14lb. per square inch. I should be glad of any information upon the matter from anyone who will give it.—J. G., Bristol.

[56577.] — **Soap.**—Yes; cotton-seed oil (not deprived of its stearine) is used very largely indeed on the Continent in the manufacture of soaps, especially "silicate" soaps.—Percy W. Stanley, 119, Manchester-road, Poplar, E.

[56584.]—**Silvering Solution.**—Roseleur's bisulphate of silver method is by far the best, but rather tedious. The following gives fairly good results, though not to be compared with the above, which is almost as permanent as electro work: Dissolve 1 part nitrate silver in 20 parts water, and add ½ part sal-ammoniac. You will then get a precipitate of chloride of silver, which will dissolve on the addition of 2 parts of hyposulphite soda; add to the clear solution 2 parts of a milk of chalk and water, and it will be ready for use.—Percy W. Stanley, 119, Manchester-road, Poplar, E.

[56587.]—**Telephone System.**—The Leclanché No. 2 cell is the best. A ten-cell Leclanché is on at each station, arranged so as to use the whole ten cells for outward ringing and only four for the transmitter. There is a circuit with seven stations connected up on this system between Goole and Knottingley (length of line wire about 16½ miles), and has been working well for the past two years; could mention several others. Are you certain that you obtained a good earth at the stations which failed? Of course, for short circuits, say, under two miles, a six-cell Leclanché would do at each station and two of the cells for the transmitter, though for long telephone circuits it is best to use the magneto call bells with two to four cells Leclanché for transmitter. Will "S. M." kindly tell me how "intermediates" may be called up, as he says they are not in circuit when telephone is on hook.—R. F. S.

[56600.]—**Focal Distances of Images (U.Q.)**—This query has been overlooked by our mathematical correspondents, or, perhaps, not answered because an exact reply would be difficult of expression without algebra; but if the querist is willing to neglect the aberrations in the mirror, and the aberrations and nature of the glass in the lenses, perhaps the following will answer his purpose: Multiply the distance of lamp from mirror by twice the focus and divide the product by twice the distance of lamp, less twice the focus. In the case he proposes it will stand thus: $\frac{20 \times 6}{40 - 6} = 3\frac{18}{34}$, or a little over 3ft. 6in. in front of mirror, and if a double convex lens of 3ft. celestial or shortest focus be used, the answer will be the same, only the image will be the other side of the lens. Convex mirrors do not form a real image; their focus (virtual) is half their radius, same as concave.—A. N. H.

[56606.]—**Ink for Rubber Stamps (U.Q.)**—I presume by "preservative" you mean "fast" or "permanent." The usual stamp inks are simply solutions of aniline dyes in glycerol ("glycerine") and gum water, and have the disadvantage of drying slowly, and being easily washed off. This disadvantage may be got rid of in the case of dark colours, admitting a yellow colouring matter, by dissolving gum in a solution of bichromate of potash in water, so that the glycerol becomes mixed, and the colouring matter, if not of a dissolvent nature, is "buryed." As a substitute for glycerol, water-glue has some excellent properties, especially that of making the impressions fast after drying. Vermilion and Prussian blue would be the best colours, if you do not care to use the aniline dyes.—Percy W. Stanley, 119, Manchester-road, Poplar, E.

[56620.]—**Steam-Carriages.**—Apropos to or with "Nun. Dor.," "Progress No. 2," and whom it may concern, I beg sincerely to inform them that a practical system of steam tramway locomotion is manipulated daily upon the common or ordinary traffic road now in existence from Stamford-hill in Tottenham to Ponder's End, and *vice versâ*. As the writer has had the opportunity and pleasure of witnessing the usual working of the engines and cars, he can speak favourably of the result. There appears no steam or smoke emissions from the chimneys, and the usual noise through the general working is no more, or as much as when worked formerly by horses. The stoppages and startings are effected in about a similar time, and with as much ease, certainty, &c., as was done on the former system. Taking into consideration all facts, I am apt to believe it ought to be called "Progress" decidedly, especially as I have been informed that the usual life of horses employed in pulling tram-cars is, on an average, five years; also, as steam has practically superseded horse labour in the mentioned direction, surely it is worthy of the title of progress. Honestly speaking, I think all those interested in progress can waste time worse than by going to Tottenham, Edmonton, or Ponder's End to witness the working of the steam locomotive and car tramway, and kindly apprise our brother readers with the result.—E. F. Baker.

[56620.]—**Steam-Carriages.**—Before proceeding further with the question of motive power and vehicles for highway roads, I think it absolutely necessary to determine as to the bearing the wheels of the vehicles are to travel on, as that will distinctly alter the conditions as to build of the carriage, also the class and power of the motor. In my letter, p. 371, I wished to refer more particularly to their future position: and looking back to correspondence which has appeared in the "E. M." since this discussion began, it may be considered satisfactorily proved that there is not any difficulty in providing mechanical power in lieu of horses; but the difficulty lies in using that power on macadam (broken stone) road, and the principal causes of that difficulty arise—first, from a rough surface of stone; and, second, from the principle of applying the power of the engine through the medium of the wheel-tire's adhesion to the road to obtain, or rather transmit, tractive force to draw the load, both of which difficulties can be overcome—the first by a better (hard level) style of road; and, second, by using the force to "propel" instead of to draw the load—a crude description of which I will attempt to give. I have seen specification and drawings of patent now filed for completion by which it is proposed to provide either wheel tracks, each of about 8in. to 12in. wide on surfaces, or "ways" of about 6ft. wide, the whole surface of which can be made to same pattern, either of iron or of artificial stone, and thus give a bearing for either flange wheels or any description of vehicle, from a bicycle to an omnibus or tramcar, with wheels of any width within the width of "way." Most of the correspondent's notions seem fixed on steam power. I had an idea of having a steam-carriage built, but weight was an obstacle I could not overcome, and which being the cause of such a great increase in first cost and after maintenance of road, that I have abandoned steam in favour of gas as a motive power. As inventors are by other people at first supposed to be rather crazy, they will, no doubt, dub me so when I say I am preparing to build a train of five vehicles, close-jointed as one carriage, and almost turn a circle within its own length; four of the vehicles will seat ten persons each (on a double seat back to back), the other will seat two persons (driver and lad), also contain reservoir of compressed gas; each vehicle with its own small gas-engine will propel itself by the piston's pressure direct on the road (approaching the action of a horse's foot on the ground), the gas to ignite by electricity under command of the driver. The same description of train-carriage (minus the gas arrangement) can also be worked either by pedal or hand power of the passengers, and all cost of motive power avoided. Of course the iron bearing and flat tire wheels are included as part of the arrangement. As I have stated before, I believe there are very great undeveloped advantages pertaining to the joint use of the iron rail and mechanical motive power, and which ought to be brought into more general use. There are still seven or eight queries and statements in my letter on p. 328 I should like discussed for mutual advantage; ridicule, the unfailing fate of new notions, can be dispensed with until our ideas are better comprehended.—Progress No. 3.

[56626.]—**Fermentation in Horehound and Hop Beers (U.Q.)**—Does a "Poor Brewer" fine, or, still better, filter before bottling? Almost all "brewers' chemists" sell various "preservatives" or "antacids," or "antiferments," for the purpose of preventing secondary fermentations. The best of these is, perhaps, dry calcic sulphite, as it does not impart taste as does bisulphite of lime. I shall be happy to give any further hints if desired.—Percy W. Stanley, 119, Manchester-road, Poplar, E.

[56633.]—**Cleaning Glass.**—I have never found anything to equal for this purpose a strong solution of carbonate of ammonia.—Percy W. Stanley, 119, Manchester-road, Poplar, E.

[56650.]—**Lead - Burning.**—To Mr. Davies and Mr. Holmes.—At the Inventions Exhibition, South Gallery, North Court, Stand 220, there is a machine for lead burning, &c., and also with it there is some very good specimens of work done with it at a comparatively small cost. It does away with all zinc and vitriol, and the flame is very clean and is easily regulated. Amongst other things, it is strongly recommended for safety, economy, cleanliness, and the machine can be carried and used anywhere, and the cost of charging it is but very little. I trust that if any of "Ours" get one, they will kindly give us the benefit of their experience.—W. C. Crick.

[56650.]—**Lead-Burning.**—Referring to correspondence now passing between Mr. P. J. Davies and Mr. Holmes upon the above subject, and considering the same emanated through my queries addressed to Mr. Davies, I think it would not be out of place to here state that after making the machine, I unfortunately charged the same with sulphuric acid purchased from a druggist's shop, and have since discovered this was the sole cause why the machine would not work satisfactorily, hence my letter, p. 267. I have since bought acid direct from chemical works, as per instructions, and am pleased with its results, having no trouble to contend with, and am able to say that the machine is a 6in. one, made from "Practical Plumbing Work," page 54, and will work without the least attention for about three hours. With reference to Mr. Holmes's remark that Mr. Davies always brings his book into question, I should most certainly say that well he may, for I am convinced, speaking as a practical man with about 25 years' experience, nothing better for good sound practical instruction could possibly be published, inasmuch that it is just the thing required to prevent young plumbers getting into a slovenly method of executing their work.—A Beginner.

[56679.]—**Supported Beam.**—With reference to the remarks under this heading in the "E. M." for June 19th, I have only to repeat the statement made in my previous reply. If your correspondent will carefully analyse the conditions which insure the stability of the beam, he will find that there is a tendency to break by shearing at every point. It used to be assumed that no such strain existed at the centre, but I did not think that idea was entertained nowadays. In any case, however, the correct answer to the query is that there are not any points at which the beam would have no tendency to break: otherwise it might be cut through at that point without producing any weakness. It must be remembered that, as stated by the querist, the question is one set by the Science and Art Department, and the general instructions at that exam. state that the student must confine himself strictly to the question proposed, for if he does not do so his paper will be cancelled. It is not the business of the student to discover what the examiner really means to say, he has only to deal with what actually is said. I presume, of course, that your correspondents were aware of the regulation quoted above; if they were not, I submit they were incompetent to answer the question.—Bacchus.

[56680.]—**Induction Coils.—Vertical Plan (U.Q.)**—All that is needful is to wind tightly, and maintain a uniform speed. If the disc were placed between the operator and the light, there would be no difficulty in seeing how the wire was going on; but, in practice, sections so narrow as $\frac{1}{20}$in. are never necessary, and, if employed, they would involve a great waste of space. The narrowest divisions which I have myself used were $\frac{1}{10}$in., and this was in dealing with extremely fine wire. Much, however, depends upon the quality and thickness of the covering; and in determining the dimensions of the sections for any coil, the concurrent details of construction would have to be considered.—Ernest Baugh, Haverfordwest, Pem.

[56689.]—**Battery for Electric Lamps.**—I think "Sm" ought to explain where he found the statement about the "new batteries," and possibly also apply to the "authority" for the further information he requires. I do not mean to say that such a question ought not to be put to the readers of the English Mechanic; but really there are so many of them who would like to have 14 to 16 lamps of 8 to 10-candle power capable of running for 12 to 14 hours from a battery of 16 cells that the querist ought to furnish more information himself, when some of us may be able to hunt out a battery which has hitherto been contented to hide its light under a bushel. I suppose it costs nothing for exciting materials, as the products are sold for a high price.—Nun. Dor.

[56691.]—**Water-Gas.**—The composition will depend to a slight extent on the nature of the fuel used; but in any case the bulk of the gas will be hydrogen and carbonic oxide. There is a great deal about the subject in back volumes.—Essar.

[56696.]—**Conductive Glue or Cement.**—This query is certainly a most peculiar one, for a conductive cement is readily obtained by using ordinary solder. Any of the cements that can be applied with a brush would probably be found to be non-conductors unless the litharge and glycerine mixture would do. If the plates are not thick, why not couple them by bending the corners together?—Nun. Dor.

[56704.]—**Soft Black Carbon.**—This stuff will not do for blacking, I should think, though it is not quite clear what it is. It might be used for moulding battery plates by cementing it up with treacle and carbonising.—Nun. Dor.

[56713.]—**Coal versus Coke.**—Coke is an excellent furnace fuel, but requires large grate area and free admission of air. According to some statements it is at least quite as efficient as coal from the "evaporative power" point of view.—Essar.

[56714.]—**Heat Absorber.**—I would suggest asbestos; but until the querist gives one a definite idea of what he wants to do, it is useless guessing.—Essar.

[56716.]—**Hartley's Gas Calorimeter.**—At the stand of A. Wright and Co., 1478, East Arcade, Inventions Exhibition, the querist can see a Hartley's calorimeter, and on sight will be better able to judge of his ability to make one.—Essar.

[56719.]—**Waterproofing Cloth.**—This is one of those queries which no one cares to answer. Surely, if your correspondent wishes for information on the subject, that is easily obtained by making a few experiments. He may, however, be told that all solutions of the kind should always be made with hot water.—T. J. M.

[56720.]—**Mirror Painting.**—Clean the glass thoroughly, and paint with oil-colours, such as are used by artists. See p. 520, Vol. XXXIX.—Mirror Painter.

[56724.]—**Accumulator.**—"P. T. H." should pay a visit to the Inventions Exhibition, but how long the accumulator would "last" depends on what is meant. If its age is meant, that depends on the arrangement and how it is treated; for its capacity for lighting at one spell, that depends on its size and charge.—S. P. T.

[56729.]—**Clock Winding.**—Surely this query is of no interest to anyone but the questioner. He must make his private arrangements himself, and if he does not know what he can do for a given sum, he does not understand his business.—T. J. M.

[56730.]—**Six's Register Thermometer.**—Try the effect of gentle heat, which will vapourise the spirit and cause it to take its proper place. Shake gently, so as to give it an opportunity of escaping from the mercury.—Philos.

[56732.]—**Dyeing Damask Curtains.**—If this querist cannot refer to back numbers he had better give his curtains to the dyers. On no account must he dose with Judson's dyes.—Dyer.

[56744.]—**Softening Water.**—I find the Porter-Clark process a perfect success in softening water, so far as regards carbonates (of lime or magnesia) by the use of caustic lime only. But, in the case of sulphates (of lime and magnesia) also present in the water, I find it necessary to add carbonate of soda with the caustic lime. This prevents all hard scale in steam boilers; but there is still some precipitate of soft mud in boilers; therefore the filters do not appear to keep back all insoluble matter. Or probably the sulphates are not decomposed (and rendered insoluble) until affected by the heat in steam boilers. If so, then the usual soap test for hardness is delusive for sulphates (on the addition of soda), as the presence of free soda will naturally neutralise the reaction of soap on lime. Perhaps some chemist will now kindly explain the correct reactions which occur.—Jib.

[56796.]—**Boiler.**—Many thanks to "J. B." for kindly drawing my attention to an error very possibly arising from the peculiarities of my caligraphy, thus leading the compositor to set up 2oz. when it should have been 2lb. My rule is as follows: Multiply area of valve in square inches by pressure of steam required. Divide total length of the lever by the distance of the centre of fulcrum to centre of valve to find the ratio; then divide the first product 12·00 by the ratio 6, which will give the weight required in pounds.—in this case 2lb. Weight of valve and lever in such a small valve not included in the calculation, but allowed for, as you will see in my reply as estimated.—Invicta.

[56813.]—**Fracture of Water-Gauge Tube.** "Nun. Dor.," in commenting upon my reply to this query, appears to have floundered out of his depth, and his remarks lack the sound sense we are accustomed to expect in all his statements. I unhesitatingly dispute the assertion that glass tubes often break after they have been cleaned, unless, indeed, the man who cleans them is culpably careless. I have never known an iron wire to scratch a glass tube, and it is certainly not the means usually employed to break them. If "Nun. Dor." has been told that this is the case, he has been grievously misinformed.—Bacchus.

[56847.]—**To Mr. Lancaster or "Rob. Crus."**—Neither the 40in. nor the 50in. o.g. would be preferable on account of its focal length simply. The shorter focus is long enough for anything in the ordinary way astronomical, and too long for a portable terrestrial glass. The longer focus would be nice in use on the moon, if its optical condition was good. You don't say if you mean to make your o.g.—Rob. Crus.

[56856.]—**Engine Query.**—The replies given by "R. W." and "A. B. C." are both incorrect, or there is a misprint, as they will find on looking through the figures again. According to the working of the latter, the excess of work done over power of engine is 293·333 foot-lb. The question should read *gauge* pressure, not pressure on piston, which would then give a pressure of 25+15=40lb. per sq. inch. Then, working as follows, you get the right answer. Work done in six minutes in foot-lb. = 400 × 2240 × 10 = 8,960,000.;Power of engine developed in six minutes = 400 × 40 × 4 × 2 × 15 × 6=11,520,000. ∴ No. of foot-lb. lost = 2,560,000, or $\frac{2}{9}$ths of the power. I may add this question and the two following ones are from Prof. Goodeve himself, and not from someone bearing his name, as suggested by "Invicta" in yours of June 26, and were set by him in a recent examination. The above is a favourite "catch" of the Professor's.—Fred. A. Robinson.

[56859.]—**Vertical Galvanometer.**—The detector of which "M.M.I.Sc.S." speaks, probably fails from its pivots being too short for their holes, so that when laid on its back the axis of the needle takes its bearing on the shoulder of the pivot instead of on its sharp end; this should not occur in a well-made instrument. Of course, as "Sigma" so well explains in your last issue, it cannot be used in this position as a *galvanometer;* its use as a galvano*scope*, to detect if a current passes or not, is all that is spoken of by "Culley." For the rest, I can add nothing to "Sigma's" reply; but I may inform "Os." that at a time when no more sensitive instrument was to be had, I often found I could detect a leak in a wire with the detector when horizontal which I did not detect when it was vertical, and I think it useful to describe this way of making the apparatus more sensitive in case of need.—R. S. Culley.

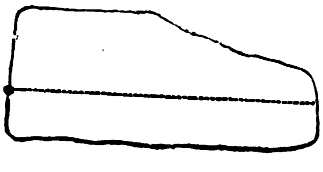
[56878.]—**Mineral Water.**—Acetic acid is used very largely in the making of aërated waters in some of the large towns. It is only fit to use in goods for a shop trade to be sold at 1d. per bottle, and makes very decent stuff. It is not so very much like drinking vinegar and water as "Os" seems to imagine. Of course, only the best must be used—either Champion's or Beaufoy's. Don't use pyroligneous acid. Quantity: 4oz. to one gallon of syrup.—Carbonado.

[56882.]—**Catalogue for Lending Library.**—If I were to compile a catalogue for a lending library I would first arrange the books under their titles, next under their author's names, and thereafter under the subjects upon which they treat as astronomy, fiction, &c.; of course, in every case they would be arranged alphabetically and would have their numbers opposite. By this means, when only the title or author's name is known, the book can be at once found, and any person wanting a book upon any subject would find it under its heading. As to bookkeeping, I would keep two books, one ruled with three columns, with the reader's name at the top. In the first column I would enter the date (in figures) when the book was given out, in the middle column the number of the book, and when returned would mark the date in the third column. As these columns are very narrow, three or four could be put in a page. The second book would contain only the numbers of the books, and when a book was given out I would mark the page and column opposite the number of the book given out, so that, if a book were to be missed, by turning up its number the page and column containing the name of the reader who had it last could be found.—James M'Cash Govan.

[56884.]—**Gramme Dynamo.**—About 9in. long, 3in. diameter; substance of ring $\frac{3}{8}$in., height of cogs above the ring $\frac{1}{4}$in.—S. Bottone.

[56895.]—**Cutting Wards of Keys.**—I cut those that are required about the house with a hacksaw or with a file. I should fancy that a small emery wheel would do very well for the purpose if you used it lightly.—Thos. H. Hall.

[56903.]—**Steam.**—A non-condensing engine is one which exhausts into the atmosphere, and so has a constant back pressure upon the piston of 15lb. per square inch, thereby reducing the effective pressure by that amount. A condensing engine, on the other hand, exhausts into a condenser, the construction of which will be found fully explained in issues June 5th and 12th, in replies to query No. 56699 by Mr. Plucknett and "Invicta." A jet of water coming into contact with the steam escaping from the cylinder condenses it, and creates a partial vacuum, thereby reducing the pressure on the back of the piston to about 4lb. per square inch. Assuming this to be the pressure, obviously the gain in effective pressure will be 11lb. The diagram shows roughly the advantage gained by condensing. The dotted line represents the line of atmospheric pressure; and if the engine were non-condensing, the part above this would represent the power. But if the back pressure is reduced as shown above, the indicator pencil drops, and increases the area of diagram, such increase accurately representing the gain derived from using a condenser. In reply to the third part of this question: By Boyle's law, the pressure of a gas is inversely as the space it occupies; therefore, by dividing stroke into five parts, the pressures at the points will be 55lb., 27½lb., 18⅓lb., 13¾lb., 11lb., which added together and divided by 5, gives an average pressure of about 25lb. per square inch. Therefore, h.p. for one stroke of engine is $\frac{25 \times 144 \times 3 \times 32}{33,000 \times 12}$ $= \frac{48}{55}$ h.p.—Fred. A. Robinson.



[56904.]—**Problem.**—"Bunsen" wants the coefficient of the middle term of $(x + a)^{4n}$. Let him, for convenience, assume $2n = r$ ∴ then the $r + 1)$th is the middle term, and is

$$\frac{2r\,(2r-1)\,(2r-2)\ldots\ldots(r+1)}{1\,.\,2\,.\,3\ldots\ldots r}$$

$$= \frac{1\,.\,2\,.\,3\ldots\ldots r\,.\,(r+1)\ldots\ldots(2r-1)\,2r}{(1\,.\,2\,.\,3\ldots\ldots r)^2}$$

$$= \frac{1\,.\,3\,.\,5\,.\,7\ldots\ldots(2r-1) \times 2\,.\,4\,.\,6\ldots\ldots 2r}{(1\,.\,2\,.\,3\ldots\ldots r)^2}$$

$$= \frac{1\,.\,3\,.\,5\,.\,7\ldots\ldots(2r-1) \times 1\,.\,2\,.\,3\ldots . r \times 2^r}{(1\,.\,2\,.\,3\ldots\ldots r)^2}$$

$$= \frac{1\,.\,3\,.\,5\,.\,7\ldots.(2r-1)}{1\,.\,2\,.\,3\ldots\ldots r}\,.\,2^r$$

and replacing the value of $r$

$$= \frac{1\,.\,3\,.\,5\,.\,7\,.\,(4n-1)}{1\,.\,2\,.\,3\ldots\ldots 2r}2^{2n}$$

—Q. E. D.

[56904.]—**Problem in Algebra.**—$(x + a)^{4n} = x^{4n} + 4na\,x^{4n-1} + \frac{4n\,(4n-1)}{1\,.\,2}\,a^2 x^{4n-2}$ + &c. The middle term of the expansion will be the $(2n + 1)$th term; and its coefficient will be—

$$\frac{4n\,(4n-1)\,(4n-2)\ldots\ldots\ldots[4n-(2n-1)]}{1\,2\,3\,4\quad\ldots\ldots\ldots\quad 2n}$$

which

$$= \frac{4n\,(4n-1)\,(4n-2)\,..\,(2n+1)}{1\quad 2\quad 3\quad 2n}$$

$$\times \frac{2n\,.\,\overline{2n-1}\ldots\ldots 3\,2\,1}{2n\,(2n-1)\ldots\ldots 3\,2\,1}$$

$$= \frac{4n\,(4n-2)\,(4n-4)\ \ldots}{2n\,(2n-1)\,(2n-2)\ \ldots}$$

$$\frac{8\,6\,4\,2 \times (4n-1)\,(4n-3)\ldots\ldots 5\,3\,1}{4\,3\,2\,1 \times (2n\qquad(2n-1)\ldots\ldots 3\,2\,1}$$

$$= 2^{2n}\,\frac{1\,3\,5\ldots\ldots\ldots\ldots(4n-1)}{1\,2\,3\ldots\ldots\ldots\ldots 2n}$$

—Geo. Smith.

[56904.]—**Problem in Algebra.**—By binomial theorem, the middle term of $(x + a)^{4n}$ is $\frac{4n\,(4n-1)\ldots\ldots(2n+1)}{1\,.\,2\,.\,3\ldots\ldots 2n}$. We have, therefore, to show that the numerator of this fraction is equal to $2^{2n}\,(4n-1)\,(4n-3)\ldots\ldots 5\,.\,3\,.\,1$. Put $n = m - 1$, and assume the theorem to be true for this value of $n$, so that

$$(4m-4)\,(4m-5)\ldots\ldots(2m-1)$$
$$= 2^{2m-2}\,(4m-5)\,(4m-7)\ldots\ldots 5\,.\,3\,.\,1.$$

Multiply both sides of this by $4\,(4m-1)\,(4m-3)$ and we have

$$4m\,(4m-1)\,(4m-2)\ldots\ldots(2m+1)$$
$$= 2^{2m}\,(4m-1)\,(4m-3)\ldots\ldots 5\,.\,3\,.\,1.$$

Hence, if the theorem is true when $n = m - 1$, it is true when $n = m$; but it is obviously true when $n = 1$, and therefore, when $n = 2$. Hence, when $n = 3$, &c., it is generally true.—C. Planck.

[56909.]—**To Mr. Bottone.**—Diameter of ring (exclusive of cogs) 4in., length 4in., thickness of ring ½in., height of cogs ⅜in.—S. Bottone.

[56913.]—**Weatherproof Paint.**—Try the patent indestructible paint, sold in several colours at 4d. per lb. I believe it resists nearly everything. —A. Richardson.

[56914.]—**Socket Joint-Making.**—Equal parts white and red lead and boiled linseed oil to form a putty is a very good cement for water apparatus, or boiled linseed oil and red lead. I would recommend "Anxious" to caulk with the following cement:—2lb. iron borings, 1oz. sulphur, and 1oz. sal-ammoniac.—A. Richardson.

[56921.]—**Heat for Workshop.**—Our Editor kindly illustrated the very thing you want on page 139. It gives 4 to 6 candle-power six hours for one penny. Perfectly safe, clean, and simple; is cheap, and lasts a lifetime.—T. Wood.

[56924.]—**Logwood and Gall Liquors.**—The strength of liquors is usually tested by an instrument styled an hydrometer. There are several varieties, the best known being those of Twaddell and Beaumé; I employ a form of the latter for this purpose. You nearly fill your solution glass with the liquor to be tested, and insert the hydrometer (a hollow glass spindle and bulb weighted at the bottom with mercury). Now, it is evident that since the weight of the liquor displaced is equal to the weight of the instrument, the latter will sink far into a light liquid, and a less distance into a dense one. The spindle is marked into degrees, 0 to 25°, the former indicating the gravity of water. I have no rules by me; but I should imagine a decoction of a pound of logwood in one gallon of water would mark about 5° B. The strength of a solution of extract compared with that of a decoction of the chips (equal weights) would probably be about 6 to 1.—Percy W. Stanley, 119, Manchester-road, Poplar.

[56930.]—**Three Problems.**—The odds being three to 1 against, 5 to 1 against, and 7 to 1 against, the chances of winning will be represented by the fractions $\frac{1}{4}$, $\frac{1}{6}$, and $\frac{1}{8}$, and the chances of losing by $\frac{3}{4}$, $\frac{5}{6}$, and $\frac{7}{8}$. The chance of—

Winning 1st and 2nd, and losing 3rd
$$= \frac{1}{4} \times \frac{1}{6} \times \frac{7}{8} = \frac{7}{192}$$
Winning 1st and 3rd, and losing 2nd
$$= \frac{1}{4} \times \frac{1}{8} \times \frac{5}{6} = \frac{5}{192}$$
Winning 2nd and 3rd, and losing 1st
$$= \frac{1}{6} \times \frac{1}{8} \times \frac{3}{4} = \frac{3}{192}$$
Winning all three $= \frac{1}{4} \times \frac{1}{6} \times \frac{1}{8} = \frac{1}{192}$

Since these are dependent events, the chance that one or other of them comes off will be given by their sum $= \frac{16}{192} = \frac{1}{18}$. Thus the odds against winning at least two are 17 to 1. If we wish to win just two, neither more nor less, we must exclude the case of winning all three, and the chance $= \frac{15}{192} = \frac{5}{64}$, the odds being 59 to 5 against. The chance of winning two running depends, of course, on the order of the events. Assuming they occur in the order printed, the chance that he wins the first two $= \frac{1}{4} \times \frac{1}{6} = \frac{1}{24}$, and the chance that he loses the first and wins the other two $= \frac{3}{4} \times \frac{1}{6} \times \frac{1}{8} = \frac{1}{64}$. ∴ The chance that he wins two running $= \frac{1}{24} \times \frac{1}{64} = \frac{11}{192}$; or the odds are 181 to 11 against. Concerning the third question, as asked, it is identical with No. 1. Possibly "Perplexed" fancies that since, if the runner wins the first two heats he has not got to run in the third, there may be some difference in the result, but such is not the case.—C. Planck.

[56932.]—**To "M.I.C.E."**—In the expression for the value of $r$ in my reply to this query, the fractions attached to the figure 2 in the numerator and denominator are intended for indices, and not as they are printed. A good sequel to this problem is to suppose *two* holes at right angles to each other bored through the sphere, the axes of holes passing through centre of circle. Find what the radius will be (both holes being same radius) when the volume of sphere is reduced by one-half. There is some very neat integration required where the two holes cross each other, and the result is also neat.—M.I.C.E., Bath.

[56932.]—**To "M. I. C. E."—Hole in Sphere —Periphery of Ellipse.**—I was glad to see that my problem had interested "M. I. C. E.," and that he had worked it out so as to obtain a definite expression for the radius of the hole. I quite agree that it is merely a chance approximation, but it is a close one. Taking "M. I. C. E.'s" figures, we have 3·648 × 2 = 7·296 for diameter of hole (I had made it 7·3), while the mean between the side of pentagon and its arc is 7·2967. As "M. I. C. E." takes such interest in questions of this nature, I will call his attention to a problem that I have been working at—viz., to find the periphery of an ellipse, say, of one whose axes are 8in. and 4in. The common rule is very inaccurate, while the more exact expression takes the form of an awkward and slowly-converging series. Looking at such an ellipse, it is apparent that the common rule of using the half-sum of the two axes as a mean radius fails, because it does not recognise the proportion of the periphery due respectively to the longer and shorter radii with which we may consider the curve to be described. In order to obtain a mean radius we must give more weight to the greater length of the flatter than of the sharper curve, and it is in this direction I have been working. Having drawn the ellipse, we will (for brevity's sake) deal only with one quadrant of it. Divide the semi-major axis into (say) 10 equal parts, and from the extremity of the minor axis draw through the points of division lines cutting the arc of the ellipse, which will thus be divided into 10 unequal parts, gradually diminishing from the centre to the extremity of the ellipse. Join each point of division to both foci (found in the usual way), bisect the angles, and draw the normals. Produce these normals till each intersects the previous one, and we shall have a series of approximate radii of curvature. Measure the lengths of these radii and the angles between them. Multiply each radius by the angle between it and the next radius. Divide the sum of these products by the sum of the angles (which will always be 90°), and the quotient will be the required mean radius. In the above example I get a mean radius of 3 082in., which gives 19·36 for the periphery, while by actual measurement I made it 19·40. I would, therefore, ask "M. I. C. E.," in the first place, what he makes the periphery of this ellipse; secondly, whether it is practicable to obtain by calculation, instead of by measurement, the lengths of the different radii and the angles between them; thirdly, whether he considers it possible to devise a general expression that shall embrace the whole, and give the corresponding mean radius? Can "M. I. C. E." also inform me what is the curve on which lie the intersections of the radii obtained as above? It is suggestive of an ellipse whose major axis is equal to twice the maximum radius of curvature, and minor axis equal to the distance apart of the foci of the original ellipse; but I scarcely think such is the case in reality, as the curve is imperfect towards the extremity where the radii are least: it is not evident how it would end if completed.—A. S. L.

[56935.]—**Choke Damp.**—$CO_2$ = carbonic anhydride = carbonic acid gas. It is formed, when an explosion occurs in a mine, by the union of the hydrocarbons in coal-gas with the air.—R. A. R. Bennett.

[56935.]—**Choke Damp.**—This is the name given to the products of combustion of marsh gas, usually termed fire-damp (and of which there are often great quantities in mines) and the oxygen of the air; the chemical name for this exceedingly dangerous gas is carbonic anhydride ($CO_2$) and the combustion thereof, expressed in a symbolic equation, is—

$$CH_4 + 2O_2 = 2H_2O + CO_2$$

The pressure of this gas after an explosion has, very often, more dangerous results, as it gives rise to suffocation, than the explosion itself.—A. B. C.

[56936.]—**Patent Law.**—No; it is a uniform rate, whether the patent be worth a shilling or a thousand pounds. You can obtain provisional protection for £1 1s. 6d., £1 the stamp, and 1s. 6d. the affidavit.—C. D. R.

[56936.]—**Patent Law.**—The fees payable to the Government are the same in all cases; but they are now reduced to £1 on the provisional, and £3 on the complete specification, so that for £4 Government fees a patent can be obtained. Of course the patent agent's fees for his services would be in addition to this £4.—Invicta.

[56936.]—**Patent Law.**—The amount payable as fee for any invention is, on application for provisional protection, 20s.; on filing complete specification 60s.; or on filing complete specification, omitting the provisional, £4. In either case protection is obtained for four years, if the application is accepted.—F. M. Rogers.

[56936.]—**Patent Law.**—The amount to pay on a patent does not vary according to the invention. First tax to be paid is £1 with the provisional specification. After filing the above, a period of nine months is allowed, during which time you must lodge a final, and pay the sum of £3. At the end of the fourth year from the date of the provisional, a fee of £50; and at the end of the eighth year from the date of the patent, £100 must be paid. But if you do not care to pay in a lump sum, the office allows it to be done by instalments of £10 10s. Any further information I shall be happy to give.—Thos. H. Hall.

[56938.]—**Electro-Magnet.**—You can fit the magnet on to a brass support without fear of interfering with the holding power.—C. D. R.

[56938.]—**Electro-Magnet.**—The power of a magnet is always concentrated at the extremity of the poles, so that a hole bored through the centre for a spindle of brass will not affect the holding power.—Bobadil.

[56939.]—**Armature.**—There are two forms of Siemens armature—viz., the old, or H-pattern, and the new or Siemens-Alteneck, or drum-pattern. Will you kindly indicate which you desire, and I will describe?—S. Bottone.

[56940.]—**Ammeter.**—A simple measuring instrument may be made by inclosing a small magnetic needle in a few turns of thick copper wire, calibrating same in the ordinary way. The needle should be as light as possible to insure its being dead beat, and should be carefully pivoted. It should be re-calibrated frequently to insure accuracy.—F. M. Rogers.

[56942.]—**Electro-Magnet.**—It is not the kind of electricity you want. If properly made, and wire insulated, a battery (preferably Daniell's) would turn it into an electro-magnet instantly.—R. A. R. Bennett.

[56942.] — **Electro-Magnet.** — "D. W." has been trying to make an electro-magnet by employing the current from a magneto machine. Ordinary magnetos are never made for this purpose. Their work is to give shocks, and nothing more. Electric bells are not rung by similar machines, but with machines entirely different.—Bobadil.

[56942.]—**Electro-Magnet.**—It is hardly to be wondered that you failed. You had nothing near sufficient wire. To get a good result you should have had sufficient cotton-covered wire to form a coil equal to the thickness of the iron; the wire was also too thickly insulated to get enough on; but six turns would be quite useless. Then, did you cross the wire from the one bobbin to the other? because that has to be done in a specific way, and not at mere haphazard, whilst the magneto-electric machine you have is not suited to produce a current for exciting a magnet.—Invicta.

[56942.]—**Eectro-Magnet.**—You say that you have used "pitch-covered wire." I suppose you mean guttapercha? Whether or no, it is of no use. Cover the legs with either cotton or silk-covered wire. There is no occasion to insulate the wire with anything save what is already on it. By using guttapercha or pitch, as you term it, you entirely destroy the effect of the current. The magneto machine will not give you a current you can utilise, and therefore all the speed you can put into it is only loss of time. You must have a battery. The magneto bells as used in some telephones are of different construction to the ordinary ones.—C. D. R.

[56943.]—**Engineer's Bookkeeping.**—There is no standard of profit in estimating cost, which varies in most shops. Cost can only be correctly carried out by embracing every item concerned—viz., rent, wear and tear of tools, use of machines, files, labour; to be safe, a slight profit, 5 per cent. or $7\frac{1}{2}$ per cent., should be added to actual cost.—F. M. Rogers.

[56948.]—**Gas-Producing Apparatus.**—You have only to refer to the back Nos. of this journal for the information you want. Look up page 374 and you will find the drawing of the generator and air-pump, whilst on page 459 will be found further details and description. If you want more information, I am always glad to give you a little help. I must say that although now some four or five of these generators made from the descriptions quoted are at work satisfactorily, yet I would prefer an oil gas to benzoline or gasoline gas. Oil gas can be made from a fairly simple apparatus, but is necessarily more complex than the benzoline generator mentioned. That is entirely automatic as driven from the engine. Oil gas requires a fire and attendance.—Invicta.

[56949.]—**Aluminium.**—Aluminium is obtained from aluminium-chloride ($Al_2Cl_6$), by passing the vapour thereof over metallic sodium. But the aluminium-chloride has first to be prepared by heating a mixture of alumina ($Al_2O_3$) and charcoal in a current of chlorine gas.—A. B. C.

[56949.]—**Manufacture of Aluminium.**—The following is Webster's process for the manufacture of aluminium:—A given quantity of alum and pitch, which are first finely ground, are mixed together and placed in a calcining furnace, by which means 38 per cent. of water is driven out, leaving the sulphur, potash, and alumina, with oxide of iron. The calcined mixture is then put into vertical retorts, and steam and air are forced through, which leaves a residue of potash and alumina only. The residue is afterwards placed in a vat filled with warm water, which is heated with steam. The potash is then leached out, and the alumina left as a deposit. The potash liquor is then run off and boiled down, while the alumina precipitate is collected in sacks and dried. It is then ready for making chloride of aluminium. The alumina deposit thus obtained contains about 84 per cent. of pure alumina, while that which is obtained by the old process of precipitation has only 65 per cent. It is certified that the constituents of Webster's alumina deposit are as follows: Alumina, 84·10; sulphate of zinc, 2·68; silica, 7·40; water, 4·20; alkaline salts, 1·62. In order to complete the process, and convert it into aluminium, the aluminium chloride is treated with sodium, in order to withdraw the metal. The operations are completed in a few days, instead of nine months (which was the time it required to complete the old process), and the product costs only about £100 per ton, instead of £1,000. The sources of raw materials are inexhaustible, and everywhere distributed; 1 cub. in. weighs ·0972lb., the sp. gr. is 2·688, and its ultimate tensile strength is about 12 tons per sq. in. The range of elasticity is large, the extension at the yielding point being $\frac{1}{200}$ of its length. The modulus of elasticity is 10,000.—P. E. W.

[56951.]—**Dynamo.**—To Mr. Bottone or "W. H. E."—Wind the magnets with No. 16. Use No. 14 or even 12 on the armature, if you require only a low resistance, and are going to wind for a shunt machine. It is almost impossible to state exactly what quantity of each is to be used, unless the external resistance is specified.—S. Bottone.

[56954.]—**Boiler Query.**—Theoretically, $\frac{3}{16}$in. thick would carry the pressure; but I would warn you that such a boiler as you describe would be unsafe. The reason is that the oval flue would collapse before anything like 80 pounds pressure was reached. I am assuming that if you used copper plates with a theoretical strength of 33,000 per sq. in. of section, at anything like 80 pounds, you would be safer with even a slightly thicker plate, as copper rapidly loses its strength when exposed to heat, such as in the furnace; but on no account use an oval firebox. Let all parts be true circles, or you will most likely meet with a very serious smash.—Invicta.

[56955.] — **Photography.** — If you consider that dry-plate photographing does not answer so well as wet plate, I am afraid I must differ from you. If you use sodic sulphite developer, you will get black negatives, similar in all respects to those obtained by the wet-plate process. I think it is ten to one that the "street photographers" use dry plates too. You will find it an awful bother after using dry plates; but "chacun à son goût"—my "goût" being decidedly for dry plates.—R. A. R. Bennett.

[56955.]—**Photography.**—(1) Yes; you can take wet-plate negatives with any instrument that can take dry plates. (2) You will find the wet-plate process described in all the cheap manuals of photography. Your reasons for going back to the antiquated wet-plate process are incorrect, and rather show that you must improve your working of the dry plates. All trade photographers use dry plates, and you are quite in error in thinking that they take longer to develop and fix than wet plates. If you wish to turn out work like that exhibited in the streets, you will require to expend some money, beginning with, say, a Dallmeyer portrait lens at £23.—B.Sc., Plymouth.

[56956.]—**Ball Bearings.**—I am not at all surprised he has found his ball bearings have worn away as he states: it shows the amount of friction that has been going on, and hence the amount of unnecessary work. My advice to all bicycle riders is to avoid all ball bearings—it's quite a mistake, and no engineer in his senses would think of using them for the bearings of an engine or any other machine. If you want a bicycle to run easy, have the bearings made as wide as possible and made of the very best gunmetal, and well fitted, then you will find your bearings will hold their lubrication and run easy and last longer than any other bearings.—Chas. Hosken.

[56957.]—**Ball Bearings.**—I may add to the remarks of this gentleman that a mechanical friend who was busy making his own tricycle, brought me for my opinion a set of balls, which he had paid full price for as steel ones, but which on a casual test he felt sure were something softer. On applying the usual test I unhesitatingly advised him that they were cast iron hardened by immersion whilst hot in acid, thus giving them the appearance and surface hardness of hard steel. On my strong representation to the makers, they stated some mistake had been made, and sent my friend a new set, which were undoubtedly steel.—Invicta.

[56958.]—**Microscopical.**—This subject was thoroughly thrashed out about six months ago in "Ours." Every device was explained and illustrated.—S. Bottone.

[56959.]—**Castings.**—Try dusting the mould with a little East Indian plumbago.—F. M. Rogers.

[56960.]—**Riparian Rights.**—The bed of a river belongs to the owners of the banks, each having up to the middle of the river opposite his bank. If the river is navigable the public have a right of way over the bed; if it is not, there is no right of way, and no one can take a boat on such a river without the leave of the owner of one bank at that part.—M.

[56961.]—**Boating.**—Innumerable attempts to propel boats by paddle or screw worked by hand or foot have been made. All have been utter failures as compared with oars.—M.

[56961.]—**Boating.**—There are plenty of water velocipedes on the Thames; but they entail a lot of hard work, and very little speed can be got out of them.—C. D. R.

[56961.]—**Boating.**—I would advise a small screw pinion of, say, 20 teeth on screw shaft, driven by wheel of 60 teeth. Some years ago I saw quite a large boat propelled by an arrangement of this kind, and I believe it answered well.—F. M. Rogers.

[56961.]—**Boating.**—"Aqua" can see a small boat at Blackfriars Bridge fitted with paddle-wheels and worked by hand or foot power, or both; it is adapted for one or two riders, and will go eight miles an hour, with half the labour of rowing.—J. Adams.

[56961.]—**Boating.**—Yes, the plan has been tried many times. If you turn to the *Mechanics' Magazine*, No. 96 for June 25th, 1825, you will find there what is termed a "water horse." In that machine the paddles were driven by a strap put in motion by a drum turned with a winch handle. More recently we have the water velocipede of the "Wheeleries" fame; whilst in the Inventions will be found a tricycle with buoyant wheels for marine propulsion as well as on land. It would be easy for me to give you a plan of a propeller worked by handles and steered by the feet. But it is not possible to do so without you are prepared to put forth a certain amount of labour. I have seen several fairly large canoes or boats driven thus. Whilst the earlier pages of this journal will show that hand levers have been tried with a screw propeller, and with very fair results. I will help you gladly to anything within the range of possibility.—Invicta.

[56963.]—**Engine Flywheel.**—I think you cannot do better than take the dimensions of the flywheel on page 95 of the present volume of the "E. M." for your engine, the capacity of your cylinder being only 4in. less than the one for which that wheel is designed. But, as explained in that article, the particular work the engine has to do governs the dimensions of the flywheel.—J. H.

[56966.]—**Australia.**—I went out to Australia by way of the Cape in August, 1882, and, so far as my experience goes, no great expense need be incurred in outfit. I should advise six woollen shirts (not too thick), twelve pairs socks, four pairs trousers of any dark colour, two of which may be old ones for rough wear, four pairs of pants, two or three ordinary serge jackets, and one or two thin white ones, three waistcoats, and three pairs of stout canvas shoes. Collars and neckties are only in the way, for the weather after you get into the tropics is pretty warm, and trousers, shirt, and jacket are all you want. I did not observe any canvas suits worn by passengers. The great drawback to white clothing seemed to be the continual need for washing, which is generally a troublesome and inconvenient operation on board ship. It is well to be provided with half a dozen towels, a bar of soap, a good stout pocket knife, scissors, needles, threads, tapes, and a bag of odd buttons. These things may appear trifles at home, but they become invaluable when you cannot get them; at any rate, my little collection was always in request by those who had not thought of these things. Your querist signs himself a "Sick Mechanic"; but I fancy that if he answers to this description when he starts, all will be changed before he gets back, for I know of no better cure for ill-health than a voyage to Australia. There were about 200 steerage passengers on the ship I went out in, and when they came on board many of them looked thin and haggard, and showed evident signs of privation; but when they passed the doctor at Melbourne, a finer, fatter, and more healthy body of people I never saw.—C. Grover.

[56969.]—**Hydraulic Ram.**—I presume he refers to the pulse valves, if so, it is not necessary to have these valves weighted: it is only necessary to have them strong enough to stand the constant blows they receive. The reason the valves don't remain closed is as follows: When the water running down the injection pipe has obtained its greatest velocity the pulse valve closes; when this takes place, the water in the ram returns and leaves a space and a vacuum under the pulse valve, when the atmospheric pressure on the outside of the valve allows it to open, when again the water commences to run. The pulse valves must be made stronger for high fall than a low one.—Chas. Hosken.

[56970.]—**To Mr. Bottone.**—Speed, 3,000 revolutions of the armature per minute; No. of volts, about 30. Not dangerous, as such a current will not pass through the human body at all. It will give a shunt shock by the "extra current," if the contact of the brushes with the commutator be suddenly broken by lifting, &c.—S. Bottone.

[56971.]—**Insects in Telescope.**—This is a great nuisance, but may, I believe, be remedied by using a little pyrethrum, in powder. Insects of all kinds seem attracted by this substance, and soon become stupefied and die. It should be scattered sparingly.—F. M. Rogers.

[56973.] — **Dynamo.** — To Mr. Bottone or "W. H. E."—The wire on this dynamo is rather fine. Heating will certainly ensue, when driving to obtain best results. Resistance of fields, about 2 ohms. Resistance of armature, if in four sections as stated (though this is wrong, for the four arms of Walker's armature should constitute but two sections really) will be 1⅜ ohm. I have not much practical experience with F. Walker's armatures; but I should judge you could get an E.M.F. of about 65 volts and about 20 ampères of current if driven at from 2,400 to 3,000 revolutions.—S. Bottone.

[56976.] — **Water-Meter.** — "Anxious" can easily find out how much water is wasted by means of comparison. Observe the meter while the water is using, say for half an hour, counting the "knocks" it gives, and reading the index at the commencement and end of the half-hour. Example: If it consumes 900 gallons and gives 30 knocks, that is equal to 30 gallons per knock, and the waste will be 120 gallons per hour. Or write to "Kennedy's Water-Meter Co. (Limited) Kilmarnock," giving particulars, and they will answer your query.—B.Sc., Plymouth.

[56977.]—**Load on Short Span.**—In solid beams of rectangular section the strength varies as ⅙ area by depth, and of circular section as ⅛ area by depth.

$$\begin{array}{llcl}\text{Then} & (1)\ \tfrac{1}{6} \times 8 \times 4 & = \tfrac{32}{6} = & 5{\cdot}333 \\ & (2)\ \tfrac{1}{8} \times 11{\cdot}3411 \times 3{\cdot}8 & = & 5{\cdot}387 \\ \text{and} & (3)\ \tfrac{1}{6} \times 12\tfrac{1}{4} \times 3\tfrac{1}{2} & = & 7{\cdot}146\end{array}$$

The three results are the relative or proportional strengths of the beams.—J. S. C.

[56977.]—**Load on Short Span.**—Let the strength of the first bar, 4in. deep and 2in. wide, be called 16; then the strength of the second bar, cylindrical and 3·8in. diameter, will be 18·29; the strength of the third bar, 3·5in. square and set with a side uppermost, will be 21·43; and the strength of the same with an edge upppermost will be 20·21.—Dubliniensis.

[56978.]—**Engine Query.**—Give the valve a throw of 4½in., and set the eccentric 124° in advance of the crank. The obliquity of the connecting-rod will upset the accuracy of these proportions; but it might be partially rectified by equalising the lead in the usual manner.—Bacchus.

[56980.]—**Electrical.**—As the current circulates round the iron core, it causes the passive iron to become a magnet, and consequently draws the bobbin towards it, as it would any other iron in its vicinity. All electro-magnets are on the same principle.—C. D. R.

[56981.]—**Preparing and Mounting Small Skeletons.**—Ants are of no use in this country. Maceration and bleaching is the process needed. First clean off all the flesh carefully with a knife, leaving ligaments to hold the bones together where suitable, and bore a hole through to the brain cavity so as to get it emptied, then leave the skeleton in running water if possible till the bones are quite clean, bleach in the sun, and join where necessary with brass wire.—B. Sc., Plymouth.

## UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

Since our last, "A. N. H." has replied to 56600; Percy W. Stanley, 56606, 56626; Ernest Baugh, 56680.

## QUERIES.

[56983.]—**Window Glass.**—When I lived in London some years ago, it was very common to see fixed outside of a window, a contrivance which enabled people inside of the house, to see the passers-by on the outside. Can you or any correspondent favour me with the name of the contrivance, and say how to arrange it?—Clyde.

[56984.]—**Legal.**—I keep a lodging house in Dorset; I supply them occasionally with eatables; if they require ale with them, having no license, I used to ask for the money and send out to the public house for what they wanted; but it not always being convenient to send, I keep it in the house and if ale is wanted, I give them a glass; I make no charge for it. My tariff of prices is shown in the room, and cutomers bills are made from these prices, but ale never, as I give the ale and make no charge. Can I legally do this, or am I liable to be fined for not having a license?—W. H. P.

[56985.]—**Planing Machine.**—Would the author of "Directions how to Make a Planing Machine," before finishing, give directions for making the carriage run in V grooves in top of sides of bed, with dimensions? Is the carriage as described, heavy enough to retain its position in such grooves under heavy cuts? The pinion being above the rack (the most favourable position), would a separate casting, like a flanched sleeve bolted on to side of bed for pinion shaft to come out of, be efficient, as it seems easier to make than that proposed, one bracket only being used inside? Querist thinks that it would be a great boon to many if some known firm advertised the set of castings in your paper, with these grooves planed, and also the V's on underside of carriage to fit them, at a reasonable price, thus determining the truth of the most important part of the machine, and giving a chance to a much larger number of amateurs to finish it truly.—J. C. G.

[56986.]—**Pansies.**—Can any reader who is a pansy grower, say how pansies may be protected from wireworms, &c.? Dressing the bed with petroleum and water was tried last autumn, but the bed is attacked this year, and the plants eaten off.—E. C. J.

[56987.] — **Volvox Globator.** — Will some experienced pond-hunting reader explain how this interesting object may be kept alive, also how it can be killed and mounted whole? My specimens break up into dust-like particles, and leave no trace of the original shape.—E. C. J.

[56988.]—**Siphon.** — To "Invicta" or Others.—Will "Invicta" kindly inform me on the above query? I put a siphon into a tank of water, it will not run out. I take the siphon and fill it full of water, and I put it in the tank again, now it runs out. I would like to know how it is, and if it makes any difference to the length of the pipe outside, I was told the longer the pipe, the faster the water would run.—Young Fiber.

[56989.]—**Willesden Canvas.**—Can anyone inform me what is used in the preparation of Willesden canvas and paper, and also give a description of the process?—R.

[56990.]—**Bell Telephone Circuit.**—To Mr. S. Bottone, "Nun. Dor.," and Others.—Would you kindly inform me how to connect up a pair of telephones, microphone, and one battery and coil if necessary, and using only two line wires and no earth return. Should a battery be required at each microphone, how connected up? A sketch will oblige.—Transmitter.

[56991.]—**Blown Hole.**—In the cylinder of my engine there is a small blown hole. Would any of "ours" kindly say what should be done with it? I have been advised to fill it up with solder.—C. M.

[56992.]—**Hydraulic Ram.**—Would some reader of the "E. M." kindly give me information as to the working of hydraulic rams? The one I saw working was for pumping water to the cistern of a house, situated about 80ft. above the ram, and the water which supplied the ram had a fall of about 9ft.—Cumbrian.

[56993.]—**Water Analysis (Qualitative).**—Would some chemical friend kindly describe a simple process, whereby a sample of water can be tested qualitatively for sewage contamination and other impurities likely to be found in spring or river water? Is there any simple way of estimating the degree of hardness of water?—Cumbrian.

[56994.]—**Lobster Back Cowl.**—Many thanks to "Glatton" for his reply. Will he kindly inform me if he has ever seen one with the laps as he described, and would he answer my query about copper band.—Plate Worker.

[56995.]—**Fixing Boiler.**—Would anyone advise me the best way to fix a plain boiler 3ft. by 2ft., with one 1½ stay, to drive an engine 3in. by 5¼in.? Also, how full to keep it in water, and what pressure to use? It is a ⅜ plate, with single rivets, and appears in good condition.—H. B.

[56996.]—**Melting Points of Gums and Resins.**—I should be glad if someone would kindly give me a list of gums and resins (such as shellac and rosin) which are liquefied by heat, with their melting points?—J. L.

[56997.]—**Hydropathy.**—Having been troubled with nervous headache and depression for a long time, and not receiving much benefit from several doctors whom I have been under, I was induced to try cold water sponging, &c., which is much recommended as a great tonic for the nervous system, but from which I have not derived the benefit I expected. As I am probably wrong in my mode of procedure, having nothing but a tub of water and sponge, possibly some of your numerous readers will be able to give a few simple directions in the "cold water cure" as to the best way to brace up the nervous system and avoid depression after. As this is a subject which will no doubt be of interest and benefit to many readers of the "E.M.," I shall be glad if those who can do so will give us a few wrinkles, for which no doubt they will receive the thanks of many, besides—Quixote.

[56998.]—**Vibration from Steam Hammers.**—Will any reader kindly inform me how to prevent the shaking of the beds in houses situated near to steam hammers.—No Sig.

[56999.] — **Question in Algebra.** — If twelve soldiers and twelve sailors be drawn up in line, in how many different ways can the twenty-four men be arranged so that four soldiers, and not more than four, shall always stand together?—Geo. Smith.

[57000.]—**Spark Coil.**—I have a spark coil in parts, and now wish to put it together. I am puzzled to know how I am to unite the tinfoil of the condenser with the silk-covered wires which come one from the pillar the other from the spring; all seem too delicate for common soldering with a hot iron. Will some expert tell how this is done and oblige?—Young Spark.

[57001.]—**Carbon.**—If I place a large carbon between two plates of zinc like as is done with silver and zinc in a Smee cell, will this simple arrangement, excited with a solution of common salt (chloride of sodium) have power to work a coil, a bell, or a motor of any kind?—E. B. Fennessy.

[57002.]—**Voltaic Cell.**—I find in the syllabus of the science school of Kensington instructions for making a voltaic cell which consists simply of a piece of carbon, such as is ordinarily used for electric purposes, and a length of iron hoop, the exciting liquor being ferric chloride. Will some friend say if such a battery will answer for working coils for bellringing? The carbon and iron are cheap and easily procured, but what about the chloride of iron. Is it an expensive salt? Can I make it from sulphate of iron?—Far Away.

[57003.]—**J. K. P.'s Gas Engine.**—Will "J. K. P." letter No. 24378, page 348, kindly say the quantity of gas consumed in his gas-engine per hour? I have a new gas lamp that gives a pure flame with very great heat—can it be utilised to make the gas as wanted?—T. Woon.

[57004.]—**Grinding Machine for Polishing Sheet Iron and Steel.**—Will some friends kindly inform me a little in making the above machine? I want to grind and polish sheet iron and steel for making stands and fire-irons. I want to know where I can get emery wheels and grindstone for the purpose, and what speed they must turn? Please give me a little help, as I am quite in the dark, and oblige—Tool Maker.

[57005.]—**New Steam Motor.**—To "Invicta."—Might I take the liberty of reminding our kind and instructive friend "Invicta," that his promise relative to the "new steam motor," is still unfulfilled, and of asking him when he intends conferring a great favour, not only on myself, but I am sure on numbers of readers of the "E. M."?—J. Myles, Hanna Mount, View-road, Dalkey, Ireland.

[57003.]—**Unicomb Observatory Hive.**—I am desirous of constructing a beehive, as above, to hold six frames. Will some of "ours" kindly oblige by giving measurements and method of internal construction? Is it necessary, as the hive will be indoors, to have the case double glazed? Any hints will greatly oblige—One in the Wilds of Wales.

[57007.]—**Fishing-Rod Joints.**—Will some reader of the "E M." kindly inform me of the best composition for securing the brass sockets and ferrules of fishing-rod joints? I have tried common glue, but find that after a few weeks' fly-fishing the joints get loose. Also the best varnish or polish to finish the rod with—should it be oiled before varnishing?—Cumbrian.

[57008.]—**Granule Battery.**—Is it possible to make a six-cell granule battery in a deal box with partitions arranged so as to give solid content of 8in. by 5in. by 4in. per cell, of sufficient power to work a 5-c.p. lamp? I suppose it must be coated with marine glue; can this be procured at oilshops, and how is it applied? I hear it has an unpleasant smell. Is there any other substance for coating battery boxes with? What is the E.M.F. of an ordinary granule, charged with sulphuric acid, as a Fuller? I should prefer making above battery in wooden box, as it is very compact, and square stoneware cells too expensive. Is 8 by 5 by 4in. large enough to keep down internal resistance?—it gives nearly the same result (160 cubic inches) as 8 by 5 diameter (157 odd cubic inches) which is the usual size for round cells.—W. Y. K.

[57009.]—**High Speed.**—Will "Meteor," or any of our railway friends give some account of the running of the new Mail Express from Euston without passengers, and of the new fast 8.25 p.m. from St. Pancras; both trains started on the 1st inst.?—Traveller.

[57010.]—**Swan's Studio Plates.**—Will some photographic reader kindly give me a good developer for the above plates? I bought them from Chapman, of Manchester, and on my asking for instructions for developing, &c., his assistant informed me that "any developer would do." This is not true, as I have tried four developers, and none of the resulting plates were presentable. Any hints as to manipulation will be most acceptable.—N.

[57011.]—**Continental Railways.**—What is the composition of the briquettes used as fuel on many Continental lines, and what results do they give compared to coal?—W. B. P.

[57012.]—**S. E. Engines.**—As the Midland 19in. 7-footers are such failures, how have the two S. E. ones answered so far?—W. B. P.

[57013.]—**Boiler.**—To "Invicta."—I thank you for your reply to my query. Before fitting up the boiler mentioned in my last query, I would like to know if the following boiler would give a better supply of steam? Length 20in., diameter 11in., 5 copper tubes 1in. diameter, made from ⅛in. plates.—C. J. F.

[57014.—**Watch Jobbing.**—Will any kind reader inform me of a good watch jobbing tool for turning and other purposes—one that anyone might do nearly all the work in jobbing, as there are so many tools for this kind of work?—Lever.

[57015.]—**Steam Canoe.**—I am desirous of fitting engines into Canadian canoe, 8ft. long and 19in. wide. Would any kind-hearted reader of the "E. M." tell me the size of cylinder, boiler, and propeller required to drive it satisfactorily;—whether the boiler should be horizontal or perpendicular, and the amount of pressure it ought to be able to stand? I have a very good oscillating cylinder, 2in. bore—would this be any good

Any information or advice would be gratefully received by—W. W. Howard, 64, Charlotte-street, Fitzroy-square, London.

[57016.]—**Am-meter and Voltmeter.**—Will any of the electrical readers of this valuable paper kindly give me full descriptions, with sketches, of a simple and good am-meter and voltmeter, to measure currents of about 15 ampères, and 20 volts potential difference?—W. E. H.

[57017.]—**Electric Brake.**—I should be greatly obliged if a reader of the "E.M." would give me a full description of Howard's electric brake for tramcars, of the Automatic Car Brake Company's electric brake, or of any good reliable electric brake, that can be applied to an electric tramcar, using a current of about 20 amperes and 150 volts?—W. E. H.

[57018.]—**Gas Works.**—In the tar well at our gas works, the tar floats on the water, the overflow goes on some land. What must I do with the water—it seems stronger than the tar?—Alps.

[57019.]—**Chemical.**—Can any correspondent inform me of a chemical that will cement pulverised granite? I have tried silicate of soda, but after burning in the kiln the articles are very brittle. Would exposing them to the air for a month or two, before baking them, do? Is there any substance that would answer in place of the silicate and require no firing?—A. J. Sells.

[57020.]—**Piano Repairs.**—To Mr. Davis.—I have a piano in which the holes in the wrestplank have been bored (by mistake) so large that no pins will fit—the plank is not split. Would it answer to plug the holes with beech plugs and rebore them, using small pins? Would it be best to bore in the original holes leaving a crescent-shaped piece of the plug on one side of the pin, or make fresh holes above and below the plugged ones? If a new wrest plank is necessary, would it answer to cut away the old plank above the bridge, chipping out the beech only, leaving the pine plank intact on bracings, and on to this to glue new beech plank, securing it to bracings by bolts.—Cabinet Maker.

[57021.]—**Brush Drilling Machine.**—If some kind reader of your journal would answer me the following inquiries, I should be extremely obliged:—Two automatic brush drilling machines are working at the Inventions Exhibition, both drill, as it is called in the trade "spread work," or drill the holes upon the face of the brush at an angle. The first machine is exhibited by Raper and Co., and works very rapidly; but the principle by which the spread is obtained has been tried years ago, and was not found correct enough to use it to drill hair-brushes. The second machine, exhibited by G. B. Kent and Sons, has struck me the most. The work I have examined while there seemed quite equal to hand drilling, so far as spread and regularity of line; and it is the first machine I have seen and know to drill the centre row of an oval upright. Now, what I want to know practically, if this last machine can be worked quicker? If not, can a machine be made to work quickly, say 110 holes a minute in hard wood? Also, can this machine drill any other set of work or quantity of holes on any other shape than oval.—Brushmaker.

## CHESS.

All Communications for this department must be addressed to J. Pierce, Langley House, Dorking.

### NOTICES TO CORRESPONDENTS.

Correct solutions to 944 by G. T. Stringfellow, A. A. E. Lecluse, and T. L. Robins.

To 945 by G. T. Stringfellow, J. A. Miles (very easy and idea not new; the W B seems to be quite unnecessary), R. A. Bennett, F. O'N. H., N. and F., and E. Stanley Follwell.

To 946 by E. S., Streetgate, and Rev. W. Anderson (Old Romney).

A. A. E. Lecluse.—The list of successful competitors will be given at the close of Tourney, that is in about seven weeks. As you surmise, several are very near together.

## ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

### HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, July 8th, and unacknowledged elsewhere:—

J. Williams.—Cuttriss and Co.—G. Calver.—C. E. Peek.—C. B.—J. B. N. Ashford.—Medical Battery Co.—C. A. W.—E. Pelham.—R. B.—W. W.—Weekly Subscriber.—Morosi.—T. Handel.—Cymro Gwledig.—Jolly Miller on the Dee.—E. B. F.—Pith Ball.—A Beginner.—Montmartre.—R. B. Gant.—M.—A. Atkinson.—W. Bradbury.—Dumbarton.—A Fellow of the Royal Astronomical Society.

An Old Subscriber and Engineer. (You will find as much information on the subject as you can require in your back volumes. We known of no book on the subject. If the vapours of the hydrocarbons are mixed with air in proper proportions, a flame of any kind will explode the mixture.)—Nauticus. (How can anyone answer such a question? What was the length of tube, what eyepiece? or briefly, how did you mount your o g.?)—Bolton. (The best carbon plates are cut out of retort scurf. See p. 166, last volume, for "How to Make Carbon Plates.")—Vibrator. (See the indices for many references to such a subject. The best microphone of the kind you want was illustrated on p. 544, No. 750.)—Watchmaker. (Guthrie's "Electricity and Magnetism," Collins; Thompson's "Elementary Lessons in Electricity and Magnetism," Macmillan; and Sprague's "Electricity: its Theory, Sources, and Applications," Spon—the last-mentioned being the best, if you want to obtain a thorough comprehension of the subject.)—Puzzler. (Of course there is, by going twice over the same line. You have omitted that condition.)—Alps. (The "Gas Manager's Handbook" (London: W. King), may help you.)—H. A. (We do not understand what is meant by "more powerful.")—Igno Porto: (See the "History of the Steam Engine" in No. 828. Many steam-engines were at work before James Watt made his important improvements.)—Herman Wilson. (Tomlinson's "Mechanics," in Weale's series is suitable—Crosby Lockwood and Co., Stationers' Hall-court, E.C., price 1s. 6d.)—Lux. (If the matches will "light only on the box," we do not know how you are to get a light without the box or another light.)—Keeper. (Your query should be sent to the "Wanted" column. See Hints No. 4.)—Blowpipe. (See the indices for both in considerable variety.)—Country Mechanic. (See indices of Vols. XXXVII. and XXXVIII.)—T. C. (We do not know of any books on the subject except the pharmacopeias and similar works, which necessarily contain information of the kind. You will find recipes in back volumes; but a special knowledge is required to produce the essences which remain clear when mixed with water. Most spirituous essences when first made contain gums which are soluble in spirit, but which appear as "clouds" when the spirit is diluted with water. It is necessary to extract these gums and retain only the flavouring ethers.)—John Windsor. (You will find a full account of the "Electric Furnace," in No. 912, p. 80, Vol. XXXVI.)—T. Wood. (Perhaps they think that people would not take to benzoline, or perhaps you have applied to those who make wick lamps. At any rate, the best way will be to let the French firm make them if English firms will not.)—W. Ouin. (Will be noticed when we get round to that group.)—Velocity Ratio. (Why not procure some of the examination papers set in previous years? If you joined one of the science classes, you would be able to obtain all information of the kind.)—V. R. (The Vacuum Brake Co.'s offices are at 32, Queen Victoria-street, E.C. We do not know the price. 2. Maxton's "Engineering Drawing," Lockwood and Co.)—Young Watchjobber. (It is probably not compensated for change of temperature. See the letters on the subject in Vol. XXXVII. and earlier.)—J. E. M. (Possibly an advertisement in the "Address" column might find you a maker. We cannot undertake to do so.)—Libra, J. S. B., D. A. P., C. E. Stretton. (In type.)

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a Pink Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

**Holloway's Pills** are suitable alike for the peer and the peasant; the soldier, sailor, and emigrant may rely on them as the means of banishing sickness in all climates, and under all circumstances. They readily check bilious and feverish attacks, and prevent inflammation of the brain, liver, lungs, and kidneys.—[Advt.]

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words | 2 | 6 |
| Every additional eight words | 0 | 6 |

Front Page Advertisements Five Shillings for the first 40 words, afterwards 9d. per line. Paragraph advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

| | s. | d. |
|---|---|---|
| Twenty-four words | 0 | 3 |
| For every succeeding Eight Words | 0 | 3 |

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. | d. |
|---|---|---|
| Sixteen words | 0 | 6 |
| For every succeeding Eight words | 0 | 6 |

*** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday, to insure insertion in the following Friday's number.

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words, and 3d. for every succeeding 8 words.*

**Good Value Offered** (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—Caplatzi, Science Depot, Chenies-street, near British Museum. Established 1862.

**Telescope,** 2½in. Reflector, two eyepieces, tripod stand, in oak case, for English made Air Gun, with pump complete.—Job Blain, Albert-square, Carlisle.

Patent **Vulcanite Hydrometer,** by Savigny, St. James'-street, in case complete. Will exchange for good long-range Telescope, or Microscope.—Z., 49, High-street, Dingwall, N.B.

**Organ Bellows,** Windchests, or small Harmonium, 5 octaves, double pedal, complete except keys. Exchange for Tricycle, or 40in. Bicycle.—W. Johnson, 12, Moxley, Wednesbury.

Magnificent English Silver Lever, centre seconds, **Chronograph Stop Watch,** full jewelled, gold joints, chronometer balance; exchange £10; offers requested.—E. Pownall, Prescot, Lancs.

A large **Flywheel,** with pulley, on iron stand, steel roller bearings. Will exchange for a small back-geared Lathe.—Wetherilt, West Chapel-street, Mayfair.

New £18 **Operatic Musical Box,** 6 airs, select, richly inlaid Zither, patent winder, inlaid glass lid, all improvements. What exchange?—Seel, George's-road, Bolton.

Iron Grand £60 new **Piano,** by Grunow, all improvements, including voix celeste, treble; bronze medallion front, walnut, £25. What offers?—Seel, George's-road, Bolton.

American walnut 280 dollar new **Organ,** two new swells, 12 stops, &c., all improvements, five years' warranty, £20, part exchange.—Seel, George's-road, Bolton.

Eight Original **Oil Paintings,** signed Slater, artist; grapes, &c. Approval with pleasure. New frames, English gold; choice. What exchange in clothes?—Address above.

"**Knight's Dictionary of Mechanics,**" complete, in parts, and Supplement to date. What offers?—G. Mackie, 2, Collingwood-street, Newcastle-on-Tyne.

Double-action brass **Oscillating Cylinder,** 1in. bore, complete. Exchange offers wanted.—H. S. Scott, Neville-street, Newcastle-on-Tyne.

What offers for small **Lathe,** cash or otherwise? Bicycle preferred; value £4; wood or iron. Will deliver.—Particulars, P. Hurst, 15, Radnor-street, Plymouth.

**Clothing,** new, men and boys'. Exchange broken Bicycle, Tricycle, Lathe, or offers.—M., 14, Church-street, Oldbury.

"**English Mechanic,**" about 250 odd numbers, many consecutive, in Vols. XIII. to XXX. What offers? Whole or part.—Linscott, Ramsgate.

**Dark Slide,** quarter-plate, mahogany, double, for Lancaster's cameras; also ½-plate ditto. What offers?—F. B., 15, Southgate-road, Wood Green.

Strong and superior finished half horse-power **Horizontal Slide-Valve Engine,** cost £8. Wanted, double driving, front steering Tricycle, or horizontal Boiler, internal firebox.—Below.

Will exchange my **Ledger Copying Press** for an electric engine, electric bells, vacuum tubes, or electrical offers.—T. A. Carter, Jun., Wheat Sheaf Hotel, Bridge-street, Uttoxeter.

Pulvermacher's **Galvanic Chain Band,** an effectual cure for various complaints, cost 50s. What offers?—W. F., 5, Brand-street, Greenwich, S.E.

Valuable rosewood inlaid **Spanish Guitar,** in case, cost £21, magnificent instrument, for landscape photographic apparatus (dry plate), back-geared lathe, &c. Offers.—Scriven, Chelmsford.

**Wealden Fossils** (a lot of), comprising 30 varieties. Fish, Crustacia, Molluscs, and Plants. Advertiser requiring room, desires any offers; scientific or philosophical books preferred. See Sale Column.—R., 2, Croft Villas, Hastings.

Horizontal **Engine,** nearly finished, ⅞in. bore, ⅞in. stroke; parts of a Beam Engine, cylinder, 2in. bore, and a small Engine on cast boiler.—64, Ravenscliff-road, Kidsgrove, Staffs.

Two **Lathe Wheels,** 23½in. diameter, and crank-shaft grindstone, &c. Wanted, offers. Stamp for reply.—Apply as above.

Good exchange for ¼ or ½-plate **Camera,** Lancaster's Le Merveilleux.—Roberts, 31, High-street, Mold.

Splendid new Silver Lever **Watch** (Benson, London), compensated balance, jewelled movements, cost £6. Wanted, large portrait lens.—W. J. Brown, 46, Foregate-street, Worcester.

"**Colenso on the Pentateuch,**" 3 vols., published 21s. 6d. "Apocalypse revealed, Swedenborg," 2 Vols., 6s. or offers.—F., 60, Plimsoll-road, Finsbury Park, N.

Handsome **Micro. Slide Cabinet,** holds 1,000 flat, solid mahogany, glass door, equal to new, 84s., or part exchange.—F., 60, Plimsoll-road, Finsbury Park, N.

Compound **Slide-Rests,** Jaw, Drill, and Bell Chucks, Eccentric Rests, Headstocks. Offers.—W. Bundy, 62, Holborn Viaduct, London.

**OFFICES:**

No. 54, CHEAPSIDE, LONDON, E.C.

## PROSPECTUS.

This Company is formed for the purpose of taking over and carrying on the well-known business of the London Stereoscopic and Photographic Company, which was founded by the late Lord Mayor (Mr. Alderman Nottage) and since carried on for upwards of 23 years with great success at 54, Cheapside, and 108 and 110, Regent-street, in co-partnership with Mr. Howard John Kennard, and latterly with Mr. C. G. Nottage also. The death of the Lord Mayor renders it desirable to provide for the continued conduct of the business under the facilities provided by the Joint Stock Companies Acts, but Mr. Nottage will continue to direct the management of the Company as Managing Director, while Mr. Kennard will act as Chairman.

The Company will acquire the Firm's Freehold Manufactory and Works at Southgate (erected in 1881), as well as the Leasehold Premises of the Firm at 54, Cheapside, E.C., and Regent-street W., together with the Machinery,. Plant, and Stock-in-Trade. The Cheapside Premises are held on a Lease, of which 22 years are unexpired, at the nominal rent of £400, which was accepted in consideration of the premises being pulled down and rebuilt in 1874. The Regent-street Premises are held on Leases, of which 5¾ and 13 years are unexpired, at rentals of £350 and £450 respectively.

The Vendors agree to accept for the Works, Leases, Plant, Stock-in-Trade, and Goodwill, the sum of £90,000, one-third of which they will take in 6,000 fully paid-up Shares of £5 each.

The Business will be taken over by the Company as from the 31st December, 1884, the profits for the present year, when ascertained, being divided between the Firm and the Company in equal shares. The Vendors, however, agree that the expenses connected with the recent Amateur Photographic Exhibition shall be borne by them exclusively.

The profits of the Business for the last 23 years (as certified by Messrs. R. MACKAY and Co.) have averaged £6,280 per annum, and for the year 1884 they exceeded £6,700.

The existing net income of the Company is therefore sufficient to pay Seven per cent. on the Capital (or £6,300), leaving a surplus for the expenses of the Board. The Directors will not receive any remuneration until Seven per cent. has been paid on the Ordinary Shares, but they will then be entitled to £700 per annum. During the present year the sales have largely increased, especially in connection with the Amateur Photographic Business, and from an examination of the accounts, there is every reason to anticipate that the profits for the present year will exceed those of last year.

All expenses of and incidental to the formation of the Company are borne by the Vendors, so that the Company will commence business without any outlay for preliminary expenses.

A contract has been entered into, dated 1st July, 1885, and made between CHARLES GEORGE NOTTAGE and HOWARD JOHN KENNARD of the one part, and SAMUEL MARK CLARK as Trustee on behalf of the Company of the other part. There are in addition other Contracts that have been entered into in the ordinary course of the business of the old Partnership, which it is impossible to specify in this Prospectus, and reference to which must be considered as waived.

Of the 12,000 Shares now offered for subscription 1,000 will be reserved for preferential allotment to amateur photographers or customers of the Firm.

Applications, accompanied by a deposit of 10s. per Share, should be made on the accompanying Form. The balance of £4 10s. per Share will be payable on Allotment.

The Memorandum and Articles of Association of the Company, and the above mentioned Contract, may be inspected at the Offices of the Solicitors of the Company.

Prospectuses and Forms of Application for Shares may be obtained from the Bankers and Solicitors, or at the Company's Offices, No. 54, Cheapside, E.C., and 108 and 110, Regent-street, W.

In the event of no Allotment being made, the deposit will be returned in full. If a smaller number of Shares are allotted than applied for, the surplus will be credited towards the amount payable upon Allotment.

## THE LONDON STEREOSCOPIC AND PHOTOGRAPHIC COMPANY, Limited.

## FORM OF APPLICATION FOR SHARES.

To the Directors of the LONDON STEREOSCOPIC & PHOTOGRAPHIC COMPANY, Limited.

GENTLEMEN,—Having paid to your Bankers the sum of £ .................................. being a deposit of 10s. per Share on .................................. Shares, I request you to allot me that number of Shares, and I agree to accept the same, or any less number that may be allotted to me, and to pay the balance in terms of the Prospectus, and I authorise you to insert my name on the Register of Members for the number of Shares allotted to me.

Usual Signature ..................................................
Name in full ..................................................
Residence..................................................
Profession ..................................................

Date ..................................1885.

## THE SIXPENNY SALE COLUMN.

*Advertisements are inserted in this column at the rate of 6d. for the first 16 words, and 6d. for every succeeding 8 words.*

**Motor Castings,** materials for Electric Bells, Batteries, Galvanometers, Intensity Coils, Microphones.—King Mendham, and Co., Bristol.

**Insulated Wire Table,** showing size, weight, resistance per foot, feet per ohm, &c., price 3d.—King, Mendham, and Co., Bristol.

**Standard Ohm,** in box, copper poles, guaranteed correct to ten thousandth of ohm, 21s.—King, Mendham, and Co., Bristol.

**Wimshurst Influence Machine.**—Sole Manufacturers of Improved Pattern. Numerous testimonials as to thorough efficiency.—King, Mendham, and Co., Bristol.

**Galvanometer Cards,** improved for tangent and ordinary combined, 2½in., 8d.; 4in., 10d.; 6in., 1s.; post free.—As above.

Write for **King, Mendham, and Co.'s** large new and reduced Price List, post free 4 stamps.

**Trouser Lengths,** 5s. each. Cheap Cloth for Ladies' Dresses, Mantles, Boys' Suits.—Hewitt, 27, Winfield Mount, Leeds. Patterns free.

**Electric Depot,** 10, Deansgate, Manchester.—Electric Breast Pins, 25s. Electric Bells, 4s. Induction Coils, 8s.—Millar, Proprietor.

Hard **Vulcanised Fibre** for Magnet Heads.—Mosses and Mitchell, 68a, Chiswell-street, London, E C

Hard **Vulcanised Fibre** for all kinds of insulation.—Mosses and Mitchell, 68a, Chiswell-street, London, E.C.

**International Inventions Exhibition,** East Avenue, Group 21, Stand 1683.—Mosses and Mitchell, 65a, Chiswell-street, London, E.C.

**Chemical Apparatus.** — Catalogue, 90pp., 500 illustrations, posted 2d.—W. Hume, Lothian street, Edinburgh.

**Photographic Apparatus and Chemicals** for professionals and amateurs. See new illustrated catalogue, post free.—Hume, Lothian street, Edinburgh.

**Mica,** otherwise Talc.—RICHARD BAKER & Co., 9, Mincing-lane, London.

**Vermilion,** best, 2s. 4d. lb.—PINNELL BROTHERS, 214, Whitechapel-road, London, E.

**French Polishing,** Staining, Painting, and Varnishing. 192 Recipes or Trade Secrets, with full instructions and details, post free, 1s.—I. Tomlin, 28, Highfield-terrace, Barnsley, Yorkshire.

**Castings.**—Half horse-power Horizontal, Vertical, or Launch Engine Castings, complete, with brass work and forgings, 12s 6d One horse-power, 25s.—Tomlin, Highfield-terrace, Barnsley, Yorkshire.

**Castings.**—Bench Drilling Machine Castings, complete, 3s. 6d.—I. Tomlin, Highfield-terrace, Barnsley, Yorkshire.

**Castings.**—All Brass Engine Castings, horizontal or vertical, suitable for model work, 2s. 6d. set.

**New Designs and Price List** of Perfected Engines and Castings, post free.—I. Tomlin, Engineer, 28, Highfield-terrace, Barnsley, Yorkshire.

New Illustrated Price List of **Screws, Bolts, and Nuts** for Model Work, drawn to actual size, sent on receipt of stamp.—Morris Cohen, 132, Kirkgate, Leeds.

**Oxygen Gas,** compressed in cylinders, handiest and safest for limelight.—Clarkson, Compressed Gas Chemist, Bartlett's-buildings, E.C.

**Oxygen Gas,** compressed into iron bottles, liquid nitrous oxide and carbonic acid.—Clarkson, Compressed Gas Chemist.

**Oxygen Gas,** compressed into iron bottles: prices on application.—Clarkson, 28, Bartlett's-buildings, Holborn, E.C.

Astronomical **Telescopes** of all kinds and Apparatus or Fittings made by A. Clarkson, 28, Bartlett's-buildings.

**Eyepieces.**—Huyghenian of any power to fit any telescope, 15s. each. Sun Diagonals, £1. Star Diagonals, 30s.

Astronomical **Telescopes,** second-hand, by best makers.—Clarkson, 28, Bartlett's-buildings, Holborn, E.C.

Marvels.—Double **Opera and Field Glasses** from 5s. 6d. Lists, with engravings, one stamp.—J. B. Dancer's Opera Glass Depot, 53, Hamstead-road, Handsworth, Birmingham.

**Stammering Cured by Correspondence.**—"Practical Guide," and 600 Cases, 1s. 4d. Books of testimony (1s., or returned).—N. H. Mason (B 40), 10, Stavordale-road, Highbury, London.

**Gas Governors,** reliable and durable, half inch, 7s Illustrated list free.—Caldow and Burnett, Kilmarnock, N.B.

"**Warne's Sheet Metal Worker**" to be sold, cheap, covers soiled.—94, St. Augustine's-road, Camden-square.

**Piles.**—Worst cases cured first application. Indian Ointment, sent 13 stamps.—Thomas Palmer, St. Helen's, Auckland, Durham.

**Harness Oil,** or for Caps of Wheels, 3s. 6d. per gallon.—Pinnel Brothers, 214, Whitechapel-road, London.

**How to Preserve Eggs,** and keep them fresh for twelve months. Recipe, post free, 7 stamps.—J. Wood, Booth-street, Burley-Wharfedale, Leeds.

**Cat Gut.**—Gut Hooks and Eyes for lathes and machinery.—James Bellaers, Regent-street, Leicester.

**Bellaers' Gas Stoves,** 1s. 3d., 2s. 3d., 3s. 3d., for oiling. Breakfast Stoves, 8s., 11s., 14s. 6d. Send for lists.

**Model Steam Engines,** made or repaired, separate parts fitted up, boilers made to order; sets of castings of every description.—Lucas and Davies, 21, Charles-street, Hatton Garden, London.

**Bamboo Fishing Rods,** 10 or 6-joint, 1s., 15 feet; 5-joint, 9½d., carriage 3d —Bristow and Co., Hull.

**Gas Engine,** bargain, 1-man, off Dorrington's castings, built for exhibition, no further use for it, cylinder, 4½ dia.—Wm. Ainsworth, *Gazette* Office, Accrington.

**Tic.**-This excruciating agony completely cured by Thomas Palmer's new remedy, and health and strength restored, 13 stamps.—St. Helen's, Auckland, Durham.

**Engine,** Vertical, 2-horse, £6. Semi-portable Boiler, 3-horse, £9.—79, Dudley-road, West Bromwich.

**Electro Motor,** free, 2s. 6d., with Battery 3s. 6d. Model Engine, 1s., fee. Not approved, money returned.—Below.

**Batteries.**—Bunsen's, Daniell's, Bichromate, 1s. each, in box 1s. 6d., post free.—G. Hailey, Novelty Stores, Seaforth, Liverpool.

**Launch** and other Steam Engines, Boilers, Lathes, and all kinds of machinery at reduced prices.—S. Smith.

**Propellers,** improved pattern, from 12in., to 30in., in stock.—S. Smith, Engineer, 11, West-street, Soho, W.C.

**Swan Holders,** 5s. dozen. Switches, Machines, Lamps, at large discounts.—Nicholson, 5, Rumford-place, Liverpool.

**Glass Blowing.**—Instruction given. Special apparatus, pumps for high vacua; instruments repaired.—H. Newbold, 25, Calthorpe-street, W.C

**Fishing Bait.**—"Red Ching."—This celebrated Chinese bait received first prize in Fisheries Exhibition. Will keep for years. Salt and fresh water fish attracted from a long distance in large numbers by its peculiar odour and colour, take the bait voraciously. One packet will take bushels of fish.—Post paid, 1s. 2d.—Address, Dr, Evans, Importer, Shirley, Southampton.

**American Organ,** wonderful bargain, in solid walnut wood, 9 stops, knee swell and grand organ, two couplers, rich and pipe like tone, would suit small church; owner having no use for it. Cost 35 guineas; for cash, 15 guineas. Approval, carriage paid.—G., 17, Sherbourne-street, Islington, N.

**Piano-Making.** — Instruments supplied at trade prices. Photo. and List post free. Also Piano Fittings.—W. G. Whittingham's Piano Factory, North-street, Clapham, London, S.W.

4¼in. With-Browning **Reflector,** altazimuth mounting, on angle block for equatorial motion, with screw motion, perfect condition.—Further particulars from J. Dixon, Postmaster, Kendal.

Watchmakers and Jewellers.—**Remains of Stock,** consisting of silver and jet goods, and American clocks. Exchange for good bicycle or tricycle, or offers. Invoice price about £11. Will take 20 per cent. off for cash.—Rowland, 45, Bellenden-road, Peckham.

**Do we get Heat from the Sun?** No! Every one interested in science should read this little work. By R. Humphreys. Post free, 1½ stamps.—11, Cambria-street, Fulham, S.W.

**Batteries** (to the trade). — Pint Bunsens, Daniells, Bichromates Other sizes in proportion. List free.—Below.

Small **Electro-Motors,** 14s., 24s., 78s. per dozen.—J. Hanks and Son, Seaforth, Liverpool.

**Study Chiromancy.**—Chart of the hand, with full explanation, 7d. — H. Dyke, 21, North-street, Taunton.

Three-horse **Boiler,** £4. 7in. Lathe, all iron, £3 10s. Photo 3 stamps.—M., 14, Church-street, Oldbury

**Boiler,** horizontal, all fittings, 12ft. by 2ft., £6 10s. Chaff Cutter, 30s.—M., 14, Church-street, Oldbury.

**Oils.**—Lard and Olive Oils (substitute for). Reliable information. Stamp for reply.—J. M., 6, Hamlet-street, Bootle, Liverpool.

**Ash-pan,** steel, brass-mounted, double sliding action, with under pan, 3ft. by 11in., cost £5 5s. Price 30s. or offers.—Braun, 1, Kilburn-square, N.W.

**Patents, Designs, and Trade Marks** procured at moderate rates by F. M. Rogers, 21, Finsbury pavement.

**Engine** (2 H.-P. Horizontal) and Boiler (Vertical, 4ft., 2ft., 12 tubes), good as new, £22.—G. H., 36, Hayles-street, St. George's-road, London, S.E.

**Gas Engine,** half H.-P. Otto, by Crossley Bros.; can be seen at work.—98, King's-road, Camden road, N.W.

**Type,** Cases, Leads, Ink, Rollers, Brass Rule, &c., to be sold cheap.—Stationers, 55, Rhodeswell-road, Limehouse.

**Dynamo Castings,** laminated armature, 30 candle-power, partly finished, price 12s.—R. G., Hendall House Redhill.

**Inventions Exhibition.**—Hot-Air Engines, small size, for driving models in shop windows, or for driving sewing machine or light lathes, price £9.—Britannia.

**Hot-Air Engines,** larger size, suitable for 4ft. lathe, £27.

These are both **Heated by Gas.** That at £9 cost about 1½d per day. A lady can manage it. No risk, no noise —Britannia.

**Prize Medals**—We have obtained Six Prize Medals for Lathes and Tools.—Britannia Co, Colchester.

**Lathes.**—Nearly 200 varieties. Hundreds of Parts, rough or finished. Catalogue, 6d.—Britannia.

**Model Engine Castings,** best and cheapest. See list (stamp) and compare.—Wood, Dalley-street, Broughton, Manchester.

**Read and Study** Stanley's announcements, each Sale Column from May 8. Terms last week.—Write at once.

Capital **Gas Engine,** 1½ man-power, Turner's patent, cost £30; sacrifice for £17.—Hughes, Engineer, Ross, Hereford.

**Standard Ohms,** 2s. 6d. each. Delicate Galvanometers, astatic, 5s.—S. Bottone has a few for Sale.

**Am-meters,** indicating up to 8 ampères, 5s. Voltmeters, 5s. Model Electro-Motors, 5s.—S. Bottone.

**Wheatstone's Bridges,** 5s. each. 6in. Tangent Galvanometers, glass shades, 10s.—S. Bottone, Stanley-road, Carshalton.

**New Time.**—Alter your Clocks and Watches. Twelve Sets of figures, with instructions, 6d.—Wheeler, Preston.

**Water Motors,** for sewing machines, organettes, window advertisements, 32s., 42s. List one stamp.—Wheeler.

**Fan Castings.**—Improved Registered Designs; sets 4in., 3s.; 6in., 4s.; 8in., 5s. Drawings, 4d.—Wheeler, Engineer.

**Water Motors.**—Complete one horse-power, £9. Half, £6; Quarter, £4; Eighth, £3.—Thomas Wheeler, Preston.

For sale, 48in. **Bicycle,** with bent handle, bright, with lamp, bell, keys, oilcan, &c. tyres good as new, £3 3s.—E. Boyce, Flanshaw, near Wakefield.

Hardy British **Ferns.**—Lastrea Æmula (hay scented) Oreopteris (lemon scented), Rigida, Thelyopteris, Colina, Dilitata, Asplenium, Marinum, Viride, Crenatum, Trichomanes, Parsley, &c. 15, 1s. 6d. 20 large Rockery Roots, 2s. 6d.; 50, 5s., botanically named, carriage paid.—John Burns, Fellside, Kendal.

**Old Scientific Instruments,** Broken Model Engines, &c. For estimate of cost for repairing, relacquering, &c., send particulars to H. F. Lovegrove, Optical Works, Slough, who makes this class of work a speciality.

Last 87 numbers of the "**English Mechanic,**" quite clean, for half price. — James Gibson, South Queensferry, N. B.

"**Engineer,**" 16 Vols., from 1869: "**English Mechanic,**" 1881-1885; "Science for All," first two vols.; 1 cwt. Gas Carbon. Offers.—F. Ball, Milford Works, Queen's-road, Battersea.

**Dorrington's Engine, Machine Castings** and Working Drawings. List, 1 stamp.—A. Dorrington, West Gorton, Manchester.

**Wealden Fossils,** 30 varieties, 3s., including Lepidotus and some rare Plants and Cones.—See Exchange Column.

Odd **Spiral Springs** made to order. Mattress Springs, 9d. per dozen.—James Parish, 52, Bard-street, Park, Sheffield.

**Piles cured at once** by using Dr. Farquharson's Remedy, free by post for 2s.—2, Standish-street, Burnley.

**Steam Canoes** from £30 upwards. Engines, Boilers, and Propellers for Launches. State requirements.—Cashnall, Eastville, Bristol.

**Boiler,** 5ft. 2in. diam., sound, £3.—Tom Brown, Whitfield-street, Workington.

**Gas Engines,** 1, 2, and 4 man-power, cheap and good; numerous references; guaranteed.—Ellis Butterworth, Rochdale.

For sale, **Tricycle,** back-steerer, in capital order, price £3 10s.; a bargain.—11, Regis-place, Wrexham.

For sale, Coventry Rotary **Tricycle,** balls to cranks and small wheels; perfect condition, guaranteed; only £9, cash.—11, Regis-place, Wrexham.

For sale, **Bench Lathe,** back-geared, bench and all fittings, complete. Price £5 10s.—As above.

**Sheet of Zinc,** weight about 80lb., ¼in. thick, for Batteries. Price 3d. per lb.—As above.

For sale, **Lime Jets,** Gas Bags, Slides, Retort, and other Appliances, cheap.—As above.

Whole-plate **Lens,** good condition, rackwork, diaphragms, £2.—Hennis, Houghton-le-Spring, Fencehouses.

**Photographs,** Scottish Scenery, cabinet size, extra ordinary value, 4d. each.—Address, Photo, 183, Trongate, Glasgow.

For sale, three gallons rich **Silver-plating Solution,** 21s. Instruction given.—Rousseau, Clarendon-road, Walthamstow.

For sale, six-cell **Battery,** carbons 9 by 5, mechanically worked, constant action. £2 2s. Instruction given.—Rousseau, Clarendon-road, Walthamstow.

**Incandescent Carbon Lamps,** low resistance, 3s. each. Fairy Lamps, 3s. 6d. Platinum Lamps, 1s. 3d., post free.—Todd, 14, Wentworth-road, Manor Park, Essex.

**Incandescent Lamp Holders,** new pattern, best in the Trade, 12s. dozen. Sample, post free, 1s. 3d.—Todd, as above.

£20 **Astro. Telescope** for £12 10s., party ordering having forfeited deposit paid.—Theobald, South street, Greenwich.

Brass **Slide-Valve Cylinder,** 1in. bore by 1¼in stroke, 7s. 6d.—Edward Dyson, 28, John William-street, Huddersfield.

100-light **Dynamo**; several smaller ones; Arc and Incandescent Lamps. Inquiries invited.—Warne, 39, St. John-street-road, E.C.

Powerful **Field Glass,** nearly new, in case; wanting cash, take 15s. 6d.—Foreman, 17, Albion-grove, Lewisham, London.

Steel **Name Stamps,** 3d. per letter. Figures (set), 3s. 4d Letters, 6s. 4d. per post.—R. F. Baldwin, Robinswood-hill, Gloucester.

Watchmaker's **Jacot Tool for Pivoting,** in morocco case, as good as new; cost 18s. 6d.; will take 14s.—W.C., 169, High-street, Deptford, S.E.

**100ft. Glass,** cut sizes, packed, 12s. 6d. Pamphlet, "Polarised Light as Applied to the Microscope," 3 stamps.—Holmes, Essex-road.

**Lawn Mower,** Shanks' 16in. roller, good condition, but wants sharpening, cheap.—53, Oseney-crescent, Camden-road, N.W.

**A Treatise** on the Manufacture and Medical Value of Koumiss, 12 stamps. — R. Lawrence, 63, Aitkenhead-road, Glasgow.

**Microscopic Slides,** well mounted, stem sections, double stained, 5s. doz. Sample, 8 stamps.—Balmford, 12, Bessborough-street, London, S.W.

**Lathe,** 3½ centre, planed iron gap bed, iron standards, gunmetal riggers, 7-speed wheel, double crank, slide-rest, no chucks, £4.—R. Singleton, Clifford-road, Hermit-road, Plaistow, E.

**Taper Screw Chuck,** new, fits ½in. Whitworth mandrel, 4s. free.—Franks, 21, Conduit-place, W.

43 **Photographs** finest Express Locomotives in Great Britain. Caledonian 8ft. 6in., L. and N. W. 8ft. 6in., G. W. R. Broad Gauge, &c., cost £6 once; £3.—B. Webb, Kirby-street, Ancoats, Manchester.

Two **Lanterns** for Photographic Enlarging, 15s. and 25s Splendid value.—Dyson, 28, John William-street, Huddersfield.

**Electric Indicators,** Bell, &c., royal letters patent.—Halbert Marks, 27, Penton-place, Pentonville hill. Price list trade.

A hollow mandrel **Lathe** for sale, with slide-rest and stand, complete.—M., 58, Dean-street, Soho, London.

**Gramme Dynamo,** 120 c.-p., new, made by Dale, for working with hand or power. Price £7.—H. Jones.

**Formulas Worked Out** for winding Dynamos from 10 c.-p. to 500 c.-p., 8 stamps each.—H. Jones.

**Dynamo Castings,** Jones's patent H: 8 c.-p., 5s.; 16, 5s. 6d.; 20, 6s. 6d.; 30, 7s.; 70, 16s. a set.—H. Jones.

**Dynamos,** finished: 8 c.-p., 30s.; 16, 36s.; 20, 40s.; 30, 50s.; 70, 100s. each.—H. Jones.

**Dynamos** for house lighting. — Jones's Patent Laminated Fields and Armatures, 5, 6, and 7 lights, £6, £7, and £8 each.—H. Jones.

**Dynamo Machines Repaired.** Motors, with wire, 5s. 6d.—H. Jones, 48, High-street, Lambeth, S.E.

**French Polish.**—Brown and White Hard Varnish, 4s. 6d., 5s. per gallon. Cheaper kind, 4s. 3d.

**Methylated Spirit,** 3s. 4d. All kinds of Glues, Nails, Varnishes, &c.

**Virgin Cork,** 28lb., 4s. 6d. Finest Citrate of Magnesia, 11½d. per lb.

Finest **Oil** for stoves or lamps, 6½d. Finest Kerosene 8½d. per gallon.—H. Jones and Co., Viaduct-street, near Bethnal-green Junction, G. E. Ry.

3½in. back-geared **Foot Lathe,** slide-rest and chucks, scarcely used, £7. Lot of tools and chucks, £2. Photo.—Smelt.

Geared hand **Shearing Machine** for bench, equal to new, £4 5s. Photo and metal cut, 2 stamps.—Smelt.

Enlarged Lathe and Tool **List,** 1 stamp.—W. R. Smelt, 7, Goldsmith's-row, Gough-square, E.C.

Bisschopp 1½-man **Engine**; also 2-man and 1½-horse, cheap.—Smith, Post Office, Higgenshaw, Oldham.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
*FRIDAY, JULY* 17, 1885.

## HISTORICAL NOTES ON THE CASSEGRAIN.

By DR. ROYSTON-PIGOTT, F.R.S.

THE subject takes a much wider range than I at first surmised. Owing to severe, and, I may say, long-continued and dangerous illness in my family (eleven weeks), I have found myself utterly incapacitated from writing scientific papers. "The breaking down," alluded to by A. S. L.," is thus to be explained.

With respect to curvatures for the Cassegrain, I am perfectly sure of one thing: there exists no possible method of testing the curvature of the convex mirror except by experimentally marrying it to the parabolic mirror. A rough correction may be obtained by making both mirrors spherical. In the case of the Gregorian, which has a slight disadvantage of requiring a longer tube or shorter focal length for the parabolic mirror, the convex must be hyperbolic; whilst for the Gregoriam form it must be accurately elliptical: a curve which can readily be tested without the use of the parabolic mirror at all. As already before stated, in my Cassegrain Mr. Calver, in the most praiseworthy manner, patiently figured many convexes, alternately grinding and polishing them to produce either over-correction or under-correction — or balance.

It is now time that I should say something of my experience as to its performance. My parabolic was 129in. focus; with an eyepiece of 1in. focus it magnified 129 times as a Newtonian (to which form I also fitted it); with a convex increasing the power six times the virtual focal length became 774in., or 65ft. nearly, and multiplying this by the sine of 32′ the diameter of the moon, the moon's image was, in this case, nearly 7in. diameter. I was greatly impressed with the delightful flatness of the field of view in an eyepiece having a 3in. field-glass. It presented a sharpness of definition and brilliance of detail never to be forgotten, the various terraces deepening and glistening in the abysses of the most interesting craters seemed to leave nothing further to be desired for lunar observation. The Cassegrain seemed eminently to distance the Newtonian in magnifying power: six-fold for the same eyepiece.

I have not hitherto been able to find any description of Mr. Nasmyth's 18in. reflector sufficiently detailed to show the arrangement of his mirrors; but I imagine he must have had a flat, a convex, and a parabolic. He accomplished the desideratum of a fixed horizontal eye-tube by a turn-table which could be made to rotate both telescope, stand, and observer, whilst drawing-board and eye were in one constant position. This necessitated the altazimuth form of stand, and precluded the refined adjustments of an equatorial for finding objects invisible to the naked eye. His drawings of lunar details are not soon likely to be surpassed; to wit, the minate craters visible at times at the eastern base of Pico. The form used must either have been Gregorian or Cassegrainian, with a flat at 45° interposed.

The history of this telescope is well worth writing. M. Cassegrain is thought to have invented a better form than the great Sir Isaac. Mr. Gregory, in his "Optica Promota," described a reflecting telescope very similar to Cassegrain's in 1663. Newton used a plane at 45° as small as possible, the eyeglass to which was fastened in the side of the tube as closely as possible, and the focussing was done with a screw attached to the big concave. Cassegrain's alteration was merely the substitution for Gregory's concave of a convex speculum, Gregory having already conceived the idea of piercing the large mirror for insertion of the eyeglass. Cassegrain evidently adopted the English invention. This, however, magnified much more than either Gregory's or Newton's, and on that account Sir Isaac strongly objected to the arrangement; for it was impossible in those days to execute the proper curves, and he declared this excessive amplification would render the errors intolerable.

Although correct in theory, and assisted assiduously by the optician Rieve, Gregory died without having obtained any satisfactory results. We now know that had he been able to obtain a parabolic figure for the large mirror, an elliptical figure for the smaller mirror would have obtained a final success. Newton was fully alive to the enormous advantages of a parabolic mirror, and, had means been at hand, he would have produced it. In Gregory's concaves the spherical aberrations of each tended to compensate each other. Sir Isaac says: "When I first set myself to try the effects of reflexions, Mr. Gregory's *Optica Promota* (printed in the year 1663) being fallen into my hands, where there is an instrument (described p. 94) like that of Mr. Cassegrain's, with a hole in the middle of the object-metal to transmit the light to an eyeglass placed behind it; I thence had occasion of considering that sort of construction. . . ." In the convex of Mr. Cassegrain an extraordinary degree of exactness is required in its figure, and the errors of the perimeter of the concave object-metal, caused by the sphericalness of its figure, are much augmented by the convex, whilst at the same time, it must render objects dark and confused by reason of its being overcharged with magnifying power. Nor is there any convenient remedy for this. For if the little convex be made of a larger sphere, that will cause a greater inconvenience by intercepting too many of the best rays, and if the eyeglass be made so much shallower as is necessary, the angle of vision will thereby become so little that of the object when found there will be but a very small part seen at once."

Cassegrain's invention was given to the Royal Society in 1672. M. Salvetti constructed this instrument the same year, but declares he believes the Frenchman "only devised it to disguise as much as possible his pretended new invention, which he endeavours to make anterior to Mr. Newton's most noble one" (No. 87, p. 5069). The first Newtonian was presented to the Royal Society in March, 1672; but Newton had been driven from Cambridge by the plague in 1666, when he was then busily engaged constructing these telescopes. As Cassegrain's paper was dated or received in May, 1672, he had abundant time to re-invent almost the Gregorian mentioned by Newton, substituting a convex for the little concave mirror.

In studying these records, the extreme sagacity of Newton is interesting. His objections to the French form are cogent and hold good now. The small field if viewed[*] with the lowest power of the great Melbourne telescope is apparently hardly suitable for the delineation of nebulæ for which it was specially constructed.

I shall allude more minutely to these matters further on.

(*To be continued.*)

## THE INTERNATIONAL INVENTIONS EXHIBITION. — XI.

### Clocks and Watches.

THE group devoted to clocks, watches, and other timekeepers contains a number of interesting exhibits, and is fairly representative of the trade. Some of the stands are, no doubt, little more than shops; but the majority contain one or more exhibits which are really inventions or improvements since 1862. For several reasons the stand of the American Watch Company, of Waltham, Mass., is the leading feature amongst the exhibits connected with the watch and clock industry; but it is especially interesting to those who have the mechanical turn of mind, because several of the more ingenious automatic machines employed by the company in the manufacture of watches are shown in working order. Altogether there are twelve machines in operation; but they represent only a percentage of the actual number of different machines employed to make and finish a watch, and are engaged in the manufacture of screws, escape wheels, train wheels, crown wheels, pinions, dial feet, &c. To the practical horologist, the pinion-making machines will probably be of most interest; but the general mechanic will be attracted more by the wonderfully ingenious screw-cutting machine. This machine makes jewel screws at the rate of 400 an hour, and it is so independent of human care that one attendant is sufficient in practice to look after seven machines. His principal work is to supply the hollow mandrel with a suitable piece of wire, which is fed forward through a split chuck, and is reduced to the rough shape by a cutter; then the mandrel stops for an instant or so, and a live spindle carrying the die advances and cuts the thread. The motion of the die is reversed, it is run off the screw, and the spindle retires, while the wire is advanced a sufficient length for another screw. Meantime, however, the portion of wire already threaded has been severed from the length, and is seized by a rocking arm, which carries it to a cutter situated at the back and parallel to the mandrel, which cutter, a little circular saw, slits the head, and a needle rod pushes the finished screw into the shoot leading to the receptacle. The admirable lubricating arrangements can be well seen in connection with this machine; for wherever steel has to be cut, a constant, if minute, stream of oil is supplied at the working face, which oil is taken by small gutters to a filter beneath the bench, whence it is constantly pumped to the supply pipes. In some cases, however, the oil has to be applied by an attendant. The pinions are roughed out in a machine which consists of two small lathes on the same bed; one of these is fed with the wire and cuts the staff, and also measures off the length, at the same instant forming a portion of the pinion that is to follow. The partially roughed-out pinion, when cut off, is seized by a carrier or rocking arm, which takes it over to the other lathe, where the point at the short end is cut, and the pinion has thus taken its first rough shape. This "blank," as it is termed, is then taken to another machine, where by sundry operations it is reduced to accurate gauge, and has a finishing cut taken all over it. The leaves are cut in the pinion by means of a milling-machine, which carries three distinct and different cutters in one head. This head revolves step by step as required, and rotary motion is imparted to the cutter which happens to be lowest, whilst a reciprocating movement is given to the pinion, and also a step-by-step rotating movement according to the number of leaves. The first cutter is a small circular saw, and underneath that the pinion passes as many times as there are leaves to be cut; then the head makes the third of a turn, and brings another cutter into play which forms the leaves, while the third takes a light finishing cut. These little milling tools are made of discs of steel with ten slits at equal distances around the periphery, and in order to give clearance for the rear of the teeth, a saw-cut is made from one corner of the slit at an obtuse angle. Pressure being applied round the periphery, the saw-cuts are closed, and the disc becomes a milling tool with ten teeth, which are well supported and have ample clearance. The escape wheels are made in a similar manner, except that in their case 50 are threaded on a mandrel or quill, and are cut at the same time. This quill has slits into which the arms of the wheel blanks pass, and the latter are held quite firm, while they are perfectly supported. Fifteen spaces have to be cut in the rims of these wheels, for which purpose six tools are employed, two of steel and four of sapphire. These tools are carried by a head which revolves as required, a rotary motion being imparted to the spindle of the tool which is lowest, or, in other words, nearest to the work. The 50 blanks have a reciprocating motion imparted to them, and after every "retreat" a slight rotary motion of the quill presents a fresh surface to the milling tool. Fifteen cuts having thus been made by the first tool, the head makes a sixth of a revolution, and another tool is presented to the work, an operation repeated six times, the last four tools having cutters of sapphire, which are shaped and sharpened as required by grinding them with four grades of diamond dust. The cutters in this machine run at a very high speed—in the factory at more than 8,000 revolutions per minute; but the constant stream of lubricant is found to give excellent results, and is really very economical. The Waltham Watch Company's exhibit will be found in the court devoted to America, and it is sufficiently near to Group 27 to be considered in this notice, as also are those which have stands in the Swiss Court. In walking through the group itself, we come first to the stand of Messrs. Frodsham and Co., of Gracechurch-street, who, besides a collection of chronometers and watches, show their non-magnetic compensated gold and palladium balances, working in close proximity to a permanent magnet. A curiosity at this stand is shown in the shape of several watch movements without balance springs, the motion being kept up solely by the impulse of the mainspring on the lever and the heavily-weighted balance. When finished, these watches will, of course, be fitted with springs, and they are shown to illustrate the accuracy of workmanship.

Mr. J. W. Benson, of Ludgate-hill, makes a specialty of his three-quarter plate going-barrel English lever at a low price. The advantages of the three-quarter plate, as compared with the whole plate, are not unknown to our readers; but the "Ludgate" watch is also supplied with the patent ring-band, fitted round the movement, between it and the case, which, while excluding dust, permits the employment of a larger barrel, containing a 60-hour spring instead of the usual 30-hour. By this arrangement, as only one-half of the spring is used, a fairly constant and equal power is applied to the movement, and a steadier rate of time is obtained. The maker, in fact, appears to have substantiated his claim to combine the merits of both the fusee and the going barrel without the defects of either. Amongst the elaborate specimens of the watchmaker's art shown by Mr. Benson, the visitor will be attracted by a watch which gives the time at two different longitudes, strikes the hours and quarters, and repeats them if desired. It also indicates leap year, the month, day of month, day of week, and phase of the moon. As if that were not enough for one instrument, this watch has a treble chronograph action, with "fly-back" minute and split seconds hands, so that the time of the winner and the second in a race can be taken; an alarum that can be set to any time, a thermometer, and an "up and down" hand to indicate the state of the winding action. Some of the visitors will doubtless consider a greater marvel the miniature watch, no larger in diameter than a shilling, which shows the month and day, and repeats the hours, quarters, and minutes—altogether a unique specimen of skilful workmanship. E. Dent and Co., of the Strand, besides watches and parts, exhibit their galvanic contact apparatus for dropping a time-ball, and detached pieces of machine-made clockwork; Bailey and Co., Salford, show an improved turret clock for four 6ft. dials, and a "universal clock dial," made for the Jesuit Church, Manila. It is impossible in the available space to notice all the exhibits of the different firms; but it may interest some of our readers to learn that there are not many signs of 24-hour dials, nor any great endeavour to induce the public to take up the "new time." J. Smith and Sons, of St. John's-square, E.C., show clock dials of various patterns with the 24 hours arranged on them, and their improvements in electric time bells, &c. Kendall and Dent, of Cheapside, exhibit watches with dials having two sets of figures. Two separate dials placed back to back show both old and new time. A patent clock has two dials, placed either at an angle or on a plane, showing 1 to 12 and 1 to 24 respectively, while the other has a self-changing dial—a principle applied to a watch (but without hands), in which two figures are exhibited, the one indicating the hour, the other the minutes past. A "touch" watch for the blind has a metal dial with raised Arabic figures and strong hands. Mr. R. G. Webster, of Queen Victoria-street, shows the improved gravity escapement, watch balances affected and unaffected by a magnet, a 24-hour clock with shifting dial figures seen through orifices, and a marine chronometer with improved balance. At the adjoining stand the Standard Time and Telephone Co., of Queen Victoria-street, exhibit Lund's system of synchronising by altering whan necessary the position of the minute hand at each hour by sending an electric current to all the clocks on the circuit. At this stand is a 24-hour clock dial, with the figures alternately black and red; but this is not an outcome of the "new time" scheme: it is a clock for ringing bells at any five minutes in the twenty-four hours, and is fitted with contact springs to complete the electric circuit. Twenty-four hours are necessary in this case, because otherwise if the clock were set to ring at 12 noon, it would also ring the bells at midnight. In the collection of the British Horological Institute, Mr. Whipple shows his patent watch-glasses, in which the hours from 13 to 24 are marked in red on the glass, which is an ingenious way of meeting the wishes of those who desire to read time to 24 hours. We have thus specially alluded to the "new time" scheme in order to show that, so far as the exhibitors in this group are concerned, there are few who pay any attention to it. If a demand should arise, as business men they are prepared to meet the wishes of the public; but the paucity of designs shows that they have little faith in it. As we are at the stand of the British Horological Institute, we may mention that it contains a collection of special interest to watchmakers, and at the risk of being invidious, we would call attention to Mr. Curzon's models of escapements as a notable item in the collection. For some reason or other, which we cannot attempt to fathom, the exhibits of the Polytechnic School of Practical Watch and Clockmaking have been placed in the adjoining group—that devoted to Philosophical Instruments—although Mr. Herrmann's patent trinograph (for setting off angles and distances) and the other exhibits are directly connected with the watch and clock industries.

Grimshaw and Baxter, of Goswell-road, have a splendid collection of tools and appliances, including the "Boley" designs, which have recently attracted the attention of English watchmakers. Haswell and Sons, of Spencer-street, E.C., also exhibit a collection of tools and materials, including balance springs of a palladium alloy, which are proof against rust and the effects of magnetism. These springs are also said to obviate the middle temperature error, for experiments show that whereas steel springs have an ascensional error from the extremes of heat and cold, the palladium alloy gives a small ascensional difference from the extremes and a remarkable depression in the middle. At the stand of Messrs. A. and H. Rowley, of Gray's Inn-road, we find a splendid collection of clocks, including as a centre-piece a large chiming clock with new figure work and perpetual calendar. The curtain at the top rises 1½ minute before the quarters and discloses the bell-ringers, with another figure to strike the hours. The principal exhibit of Messrs. Rowley, from our point of view, is the movement of a fine modern quarter clock, which strikes on eight bells or four gongs, has a 15lb. pendulum, and a lifting power in the going mainspring of only 4¼lb. This clock is wound and regulated entirely from the front, and as the latest specimen of the English clock manufacture is worth special attention. As our readers are aware, the so-called cheap clocks are not made in this country, the lowest-priced specimens of the horological art being the familiar 8-day clocks; but as a really good clock chiming the quarters is a desideratum in many houses, we have taken the trouble to ascertain the price, and find that it is as near as possible five guineas for the movement; or, as in a specimen shown by Messrs. Rowley, in a polished mahogany ornamental case, £6 10s. A clock like that is not to be compared to a regulator for accuracy; but it will keep time to within, say, a minute in a month (probably better than that), and, allowing for the chiming movement, is no doubt the cheapest really good clock in the market.

At the stand of A. Légé and Co., of Turnmill-street, which is in the group devoted to Philosophical Instruments, the parts of clocks are shown, including a mercurial pendulum, in which the mercury is contained in a number of tubes inclosed by a perforated cylinder, in order that the temperature of the air may more readily exercise its effects. Messrs. Wycherley, Hewitt, and Co., of Prescot, have a fine show of tools and parts of watches as made by machinery. It was the intention of the firm to exhibit some of their machines at work; but as they would have had to provide motive power themselves, they abandoned the idea, and it remains with the council to explain why an exhibit which would have been of at least as much interest as that of the Waltham Watch Company is thus put, as it were, in the background, for the Messrs. Wycherley are the representatives of the original inventors of machinery for making watches. The English Watch Company, Birmingham, show a number of their watches, but do not exhibit their methods of manufacture — perhaps for the same reason that has made the Wycherley stand a "dead" instead of a "live" one, in the mechanical sense. Postmasters and telegraphists will find a watch that will appeal to them in the exhibit of Mr. J. F. Hills, postmaster, Sudbury, Suffolk, consisting of watches with dials carrying the code letters besides the ordinary figures. Perry and Co., Holborn Viaduct, exhibit in their collection Mr. C. Lange's device for use with stem-winding watches. In the new keyless action watches the bow cannot be fastened to the pendant by a screw for obvious reasons, and in many cases the ends are simply pressed into sockets from which they are liable to escape. In Lange's patent the bow is reduced to a ring of small size, which has a stem inserted in the pendant in such a manner as to swivel within the stem and not to interfere with the winding of the watch. There are several other exhibits of more or less interest in this group, but considerations of space prevent us from naming all the firms. Those interested in horology will, however, not need to be told that they should examine closely the stand of Mr. V. Kullberg, of Liverpool-road, N., for there they will find some of the most important of recent inventions, though it is rather puzzling to account for the fact that, while some firms have large stands which are little more than shops, Kullberg's collection of high-class chronometers, &c., is rather cramped for space.

Mr. Squire, of Myddelton-square, shows a watertight watch, and his removable barrel and adjustable isochronal balance spring stud, which is intended to avoid the risk of forcing or straining the spring. Camerer, Kuss, and Co., New Oxford-street, have a collection of cuckoo and trumpeter clocks, which naturally attract the attention of visitors generally; while G. Bendon and Co., of Ely-place, show a practical improvement in their keyless clocks, which are wound by a jointed winding stem sliding in the canon or pipe carrying the minute and hour hands. A button enables the operator to pull out the stem, which, being jointed, then forms a crank by which the clock is wound as by an ordinary key. This arrangement, at all events, obviates the annoyance of a "lost key." Mr. F. Sage, of Gray's Inn-road, and Mr. N. C. Firth, of Chester, exhibit workmen's time checks which are ingenious arrangements, but are of interest only to a limited class from the practical point of view. The De Gruyter Clock Manufacturing Co., of Aldersgate-street, E.C., exhibit Warder's patent torsion pendulum clock, which is said to require winding only once a year, and there are some other exhibits which may attract attention; but we believe we have now mentioned all that are likely to interest the public, while the profession will scarcely need to be told that in the exhibit of the British Horological Institute, which includes most of our foremost horologists, they have a perfect feast, and a variety of subjects to argue about for a whole twelvemonth and longer. The exhibit of the Kew Committee will attract both the public and the profession, for the certificates are already being utilised quite outside the trade, and possibly the question in the future will be not whether a watch is a lever, a chronometer, or what not, but what certificate it obtained at Kew.

CENTRE OF ATTRACTION AND REPULSION
CENTRE OF REPULSION AND ATTRACTION

## GANT'S PATENT ELECTRO-MOTOR.

THIS motor differs from any previous type; the central part is a drum constructed of metal or wood, with as little weight as possible. The conducting wires from the pole reverser to the armature magnets are inside the drum. The armature magnets are bar electro-magnets laid parallel with the axis and connected throughout. The construction gives, with the same weight as former ones, increased leverage and momentum.

It will be seen by inspection of the sketch that by the letters N and S on the armature magnets and on the field magnets F, that the magnetic influence causes the armature to revolve in the direction of the arrows; increase of diameter giving increased power, and weight on the periphery giving momentum to its utmost value. As the two opposite plates of the pole-reverser come in contact with the springs or brushes, the polarity of the magnets immediately connected with them is reversed, without changing the others, so that the top and bottom sets of magnets continue of the same name, unless the current is reversed by a reverse connection with the battery. The armature above carries eight electro-magnets, but any even number to sixteen may be employed if requisite.

## ON SOME MATTERS IN THE THEORY OF MIRRORS.—III.

By W. BRADBURY.

THE last term, or coefficient of $y^2$, is the increment of $1/v$, or the alteration in the value of $1/v$ due to the extent of aperture. To find the increment of $v$, this small quantity is treated as a differential, and using the notation of the calculus, we have—

$$d\left(\frac{1}{v}\right) = -\frac{dv}{v^2} \text{ or } dv = -v^2\, d\left(\frac{1}{v}\right).$$

Hence, to find the aberration or change in the value of $v$, the coefficient of $y^2$ in equation (26) must be multiplied by $v^2$. It must also be noticed that whenever the sign of the reciprocal increment is positive, the focal increment itself is negative, and shows that the aberration shortens the focus. In equation (26) it will be seen that the error is negative and shortens the focus, and is unaffected by the signs of the quantities within the brackets.

Hence, the aberration for diverging rays on a concave mirror is—

$$-\frac{v^2}{2f}\left(\frac{1}{2f} - \frac{1}{u}\right)^2 y^2$$

or, in another form, without the value of $u$—

$$-\frac{v^2}{2f}\left(\frac{1}{v} - \frac{1}{2f}\right)^2 y^2 \dots\dots\dots\dots (27)$$

When the rays are parallel $v$ and $f$ are equal, and we get for the aberration for parallel rays—

$$-\frac{y^2}{8f} \dots\dots\dots\dots (28)$$

which is the common rule for spheric concave mirrors.

Equation (27) may be put in a simpler form by employing the auxiliary quantity $a$. For since

$$\frac{1}{v} = \frac{1-a}{2f}$$

we find—

$$\frac{v^2}{2f} = \frac{2f}{(1-a)^2};\ \left(\frac{1}{v} - \frac{1}{2f}\right)^2 = \frac{a^2}{4f^2}$$

so that the whole coefficient of $y^2$ is—

$$-\left(\frac{a}{1-a}\right)^2 \cdot \frac{y^2}{2f} \dots\dots\dots\dots (29)$$

This formula is applicable only to a concave mirror.

It may be useful to exhibit in a tabular form the aberration values for different focal positions.

TABLE OF FOCAL AND ABERRATIONAL VALUES.

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| $u$ | $\frac{f}{2}$ | $f$ | $\frac{3}{2}f$ | $r$ | $3f$ | $\infty$ | $-\frac{f}{2}$ |
| $v$ | $-\frac{2}{f}$ | $\infty$ | $3f$ | $r$ | $\frac{3}{2}f$ | $f$ | $\frac{f}{2}$ |
| $a$ | $3$ | $1$ | $\frac{1}{3}$ | $0$ | $-\frac{1}{3}$ | $-1$ | $-5$ |
| $\left(\frac{a}{1-a}\right)^2 \frac{y^2}{2f}$ | $\frac{9}{8}\frac{y^2}{f}$ | $\frac{y^2}{2f}$ | $\frac{y^2}{8f}$ | $0$ | $\frac{y^2}{32f}$ | $\frac{y^2}{8f}$ | $\frac{25}{72}\frac{y^2}{f}$ |
| Ratio to parallel aberration. | 9 | 4 | 1 | 0 | $\frac{1}{4}$ | 1 | $2\frac{7}{9}$ |

The last horizontal row gives the ratio of the vergent to the parallel aberration. Thus, when the radiant point is at half the focal distance in front of the mirror, the conjugate focus is at the same distance behind the mirror virtually; and the spheric error is nine times that of the same mirror for parallel rays. The second ratio 4 is meaningless, except as a quantitative result, for the reflected rays, issuing parallel from the mirror, come to no focus; but a spheric error must necessarily exist among them, and the term parallel is only applicable to a certain part of reflected rays, the vergency showing itself more and more as the aperture becomes increased.

It will be noticed that the ratios on each side of the column headed $r$ are the least, as would naturally be excepted, because the nearer the two conjugate foci approach the centre of curvature, the less becomes the spheric error.

(*To be continued.*)

## GLYCERINE AND ITS USES.*

GLYCERINE is perhaps well known to be a useful addition to the sulphur type of lotions for the hair, as the sulphide of lead which is supposed to be formed renders the hair almost as stiff as a board without some such addition.

A very recent hair dye, and one which is said to be good, may be made by dissolving freshly-prepared ammonio-tartrate of bismuth, or the ordinary scale citrate of bismuth and ammonia, in weak glycerine, and mixing this with a solution of hyposulphite of sodium in glycerine and water, and finally diluting with more water.

Teeth lotions have also come much into use, and of the many formulæ published the following is a type:—Tincture of quillaia, eau-de-Cologne, water, borax, glycerine, with colouring. Such a combination is as excellent for its purpose as it is elegant in appearance.

Almost all cosmetic solutions are greatly improved by the addition of a little glycerine. Of these we may name freckle lotions, zinc oxide and rose water lotions, calamine lotions, &c.

Liquid starch glosses and finishes have glycerine in them as a *sine quâ non*. Here is an example from *Popular Science News*:—Spermaceti, 1oz.; gum arabic, 1; borax, 1; glycerine, 2½; water, 14½; perfume, q. s. Three spoonfuls added to about 4oz. of boiling water.

Lime juice and glycerine inseparable may easily be made by the subjoined formulæ, but I cannot say how much will be the percentage of glycerine. A saturated solution of borax should first be prepared. Here is a note I made a long time ago:—"One drachm of powdered borax to be dissolved in 21½ drachms distilled water, and during solution warmed slightly to keep the temperature just a few degrees above that of a summer's day, and to insure accuracy it is perhaps better to weigh the materials into a large-size 3oz. bottle. The oily material consisted of 14 parts of oil of almond and 2 parts of castor oil, thoroughly mixed. To this quantity of mixed oil was added, all at once, 4 parts of the solution of borax as named (each being accurately measured). On being well shaken a very white uniform emulsion which did not separate resulted. I believe soap is sometimes added to this preparation to increase its white appearance and to prevent separation, but I do not know that it is a desirable addition, or that it is effectual in preventing separation." I have, up to this period, had no fault to find with my note.

*Glycerine Jelly.*—This combination may be made opaque or transparent. For the former, soap, glycerine, almond oil, and perfume are used; for the latter, isinglass, gelatine, or transparent soap, 1oz., dissolved in glycerine and a little added water, this usually being a perfumed water.

I hope, by the introduction of a few brief notes under this head, that we shall not be doing any serious injustice to the medical profession. Glycerine is reputed to be a safe and very effectual emetic for infants. As a substitute for cod liver oil, iodised glycerine with iodide of potassium forms a good tonic, &c., for phthisical patients whose stomachs are unable to bear this oil. A combination of a fluid extract of *Cascara Sagrada*, glycerine, and a little tincture of nux vomica is highly praised as a tonic laxative. Ferric chloride and its preparations are very astringent, and hence, when taken internally for some time as a tonic, are liable to do harm. This astringent effect is greatly counterbalanced by the addition of glycerine, with which this chalybeate is perfectly compatible. An excellent simple remedy, in place of the old-fashioned rum and figs, for tightness of the chest and the cough of old people, is a mixture of 40 fluid drachms of glycerine, 10 of rum, with 1 minim of oil of anise or peppermint. The combination, as an aperient, in doses of 1 drachm, of glycerine and castor oil in equal parts, is now so old that it has almost sunk into oblivion, but it is undoubtedly, when prepared *secundum artem* and with a little flavouring agent, a valuable and highly efficacious, elegant preparation. The activity of the oil is said to be increased.

An excellent application for scalds and burns is composed of equal parts of glycerine and oil of peppermint. Glycerine, as an external application, is said not to be absorbed by the skin, hence it is of especial value as a basis when such agents as a mercuric chloride, iodoform, &c., have to be superficially applied in cases of certain skin diseases, as scabies, &c. 1½ drachm, dissolved in 3 fl. oz. of glycerine, is reported to possess valuable powers in the treatment of scabies, &c.

Iodised glycerine prevents the pitting which may result after an attack of small-pox. As a liniment, in combination with chloral hydrate, camphor, &c., it receives the commendation of sufferers of rheumatism. When vaporised in a suitable apparatus, and its fumes inhaled, glycerine is a simple expedient in cases of bronchial affections and distressing coughs; and here we may remark that many eminent vocalists are fully alive to the value of this substance as a voice strengthener and throat invigorator.

Salicylate of sodium, dissolved in glycerine, has its medicinal effects greatly enhanced. A good remedy for dyspepsia consists of pepsine, sherry, glycerine, and tartaric acid.

Naphthaline, recommended as an antiseptic agent with a view to checking diarrhœa, and said to be efficacious in cases of intestinal catarrh even when chronic, may be administered in glycerine, in which it is soluble when the solvent is slightly warmed. Indirectly connected with glycerine is the use of nitro-glycerine, as a 1 per cent. solution in diluted alcohol, for neuralgia, &c.

Mercuric iodide, with glycerine, is a good paint for corns.

An excellent simple febrifuge drink is thus made:—Glycerine, 1oz., citric acid, ½ drachm; water, 6oz. Dose, one to two tablespoonfuls every hour for an adult.

Glycerine is very largely used in the manufacture of printing, stamping, and letterpress inks, as also in the preparation of inks for the numerous forms of "graphs." The following is an example of an indelible stamp ink taken from the *Pharmaceutical Record*:—Sodium bicarbonate, 22; glycerine, 85; gum arabic, 20; nitric silver, 11; solution of ammonia, 20; Venice turpentine, 10; mix according to art. For ribbon ink:—Concentrated glycerine and alcohol, of each 15; aniline ½oz. Blacking of excellent quality can be made by means of a judicious combination of soot, glycerine, oils, &c.

---

* By F. H. ALCOCK, in the *Chemist and Druggist*.

A good "graph" is readily made from Russian glue, 2; water, 1½; glycerine (1·260), 5 parts by weight. As these sometimes go mouldy, we may mention a wrinkle which will prevent the proneness of gelatine to this trouble. It is simply to dissolve a few grains of boracic acid in the glycerine before incorporating with the other materials.

In the process of vulcanising indiarubber glycerine is found to be of service. It appears that the indiarubber acquires properties which protect it from oils and fats without interfering with its other properties.

For silvering and gilding glass we find our subject again in request by reason of its reducing action on the salts of silver and gold, and also because the deposit thus produced is of a brilliant metallic lustre. An ammoniacal solution of nitrate of silver is first prepared, and in it is poured a little of caustic potash, and then a few drops of glycerine. It is then ready for immediate use, since reduction begins at once, which process is accelerated if a little ether or alcohol be also added to the mixture. The result is said to be most brilliant when a moderate heat is used, and darkness is said to favour the adhesion of the deposit to the mirror.

A polish for leather is thus made:—Shellac, 200; spirit, 1,000; Marseilles soap, 25; spirit, 25 per cent., to dissolve soap, 375; glycerine, 40; to which is finally added 5 nigrosin in 125 spirit.

Mineral water manufacturers are now availing themselves of the advantages to be derived from the use of glycerine in the preparation of the liquors and flavours, &c., which are much in request as beverages.

Glovers use large quantities of yolks of eggs in certain processes involved in the manufacture of kid gloves. An addition of a few per centums of glycerine is said to be a decided advantage. Glycerine preserves the yolks for a long time.

In the preservation of anatomical and other specimens its value is well established, but a little point will perhaps be useful to bear in mind. About six years ago a friend presented me with a nice specimen of the ripe fruit and fresh leaf, with tendrils, of the *Bryonia dioica* which I placed in a bottle with some glycerine and water, but now, although in good condition as far as preservation goes, I find the berries have become wrinkled and some have collapsed, which, I believe, is probably due to a process of osmosis, the liquid within the fruit being of a different gravity from the preservative fluid. If I had first ascertained the gravity of the juice, and made my glycerine solution of a similar gravity, if such had been possible, I think the shape of the fruit would have been retained.

For the preservation of cider, glycerine of salicylic acid is admirable, a very small quantity keeping it good for over twelve months.

A solution of alum, arsenic, and nitre in glycerine is said to be an admirable preparation for "curing" animals' skins. I have a cat's skin which has been successfully prepared with this combination.

To render corks impervious, soak them several hours in a solution composed of ¼oz. glue or gelatine, ¼oz. glycerine, and a pint of water heated to 50° C. After such a treatment they are nearly proof against many corrosive liquids, but are more competely so if they are at first well dried and then dipped in a mixture of 4 parts of paraffin and 1 of petrolatum, or simply ordinary petroleum oil.

The easiest and safest method of preparing this explosive is that which was first introduced by Messrs. Boutmy and Foucher, and which, as a new and safe method, obtained the prize of 2,500f. offered by the French Academy of Sciences. First by converting the glycerine into sulpho-glyceric acid, and in this form bringing it into contact with the nitric acid, to which an equal weight of sulphuric acid has been previously added.

The details of the process are as follows:—

One part by weight of pure glycerine (1·260) is thoroughly mixed with 3 parts of strong sulphuric acid (1·842); there is at once a considerable evolution of heat, and the glycerine is slightly discoloured. In a separate vessel a mixture 3 parts (also by weight) of sulphuric acid and 3 parts of nitric acid (1·4) is made, and both mixtures are then allowed to cool down to about 15° C. The next step is to transfer the two cooled liquids to a tall cylinder, and well stir them together, when a slight rise in temperature (to about 20° or 25°) takes place, followed, after the lapse of half an hour or so by a cloudiness of the acids, due to the separation of minute drops of nitro-glycerine. After standing for about twenty hours the formation of the oil is complete, the whole of it having risen to the surface of the acid mixture; it may then be siphoned off, dissolved in an equal volume of ether, to facilitate its separation, shaken up with successive portions of water until the washings fail to redden blue litmus, and finally heated on a water-bath until its weight remains constant. The nitro-glycerine will now be light-brown in colour, and should have a specific gravity of 1·6, and should detonate readily and powerfully when fired by percussion or by means of a fulminating charge. This substance may be easily recognised by the violent but transitory headache which is experienced on placing an exceedingly small quantity (1-1,000th of a grain or thereabouts) on the tongue.

In the old processes the nitro-glycerine separates almost instantaneously, and rises in part to the surface, thus rendering washing difficult. In the process above described its formation is gradual and extends over a long period of time.

The barometric records made for the *Times* newspaper are from a glycerine barometer. In place of the column of mercury of about 30in. length, a tube about 27ft. long is used containing ¾ of a gallon of glycerine coloured red with aniline. The great advantage of this fluid is that readings can be taken more accurately, for, when subjected to the weight of the atmosphere, while mercury would move 1-10in., the height of the glycerine column would be moved through a space of 1in. One objection has to be provided against, i.e., the hygroscopic nature of glycerine, its powers of absorbing water from the air being very great. This is remedied, however, by putting a layer of heavy petroleum oil in the cistern of the barometer. There is a glycerine barometer at the Kew Observatory which also required for its construction ¾ of a gallon of glycerine, and, in order to obtain the correct height, the tube passes through two rooms, the cistern being in one and the column read off in the one above. This fluid, on account of its high boiling point and low freezing point, is of constant use in scientific experiments. Carbolic acid is said to be an adulterant of ordinary or wood-tar creasote. The former is well known to be soluble in glycerine (glycerinum acidi carbolici), and on the addition of water forms a clear solution. Creasote forms a nearly clear solution with this liquid when of sp. gr. 1·260, but on dilution with water it separates out again.

When gallic acid is warmed for a long time with glycerine, even at a low temperature, pyrogallol results, and this process is taken advantage of by photographers, who use a combination of glycerine and pyrogallol, or pyrogallic acid, in some of their operations.

A delicate test for glycerine is to take two drops of carbolic acids with 3,000 to 5,000 drops of water, and add one drop of solution of ferric chloride; in the absence of glycerine a blue colour results, but if it be present the colour does not form. If colouring matters or sugar are present in the suspected liquid they must first be removed. To do this calcic hydrate is added to the liquid to be tested, with some powdered marble, and evaporated, and the mass then exhausted with a mixture of alcohol and ether; the alcoholic solution evaporated to remove ether and alcohol, and the residue mixed with water, and the test applied, first neutralising any alkali, should any be present. This may be available as a qualitative test for the presence of glycerine in beers, wines, beverages, &c.

The value of glycerine jelly for mounting microscopic objects needs only a passing comment; its manipulation is very easy, and well suited to the tyro embarking in the study of histology of animals and plants.

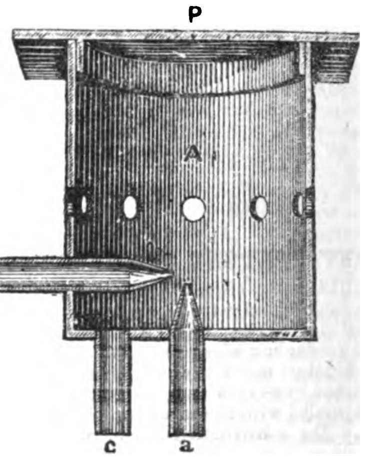
The fact that glycerine when present in a solution often greatly interferes with the usual chemical reactions should always be borne in mind. Thus ferric bromide mixed with glycerine, and then sulphocyanide of potassium added, gives the usual red colour, but ether does not remove that colour and impart it to itself. Again, if ferric bromide be added to sulphocyanide of potassium, and then ether added, we get all that we expect, but on the addition of glycerine the ether becomes colourless again. Glycerine also removes auric chloride and uranium nitrate from their etheral solutions; so, too, an etheral solution of mercuric chloride, when agitated with glycerine, is found to hand over the greater part of its solvent to the latter solvent.

Glycerine has very recently been used in a process for the preparation of chemically pure metallic bismuth. Ordinary commercial bismuth is dissolved in dilute nitric acid, and the solution mixed with water until turbidity begins to appear; then a sufficient quantity of fixed alkali is added in solution to precipitate the bismuth and render the solution alkaline; twice the volume of the alkaline solution is now added, and glycerine in sufficient quantity stirred in to redissolve the precipitate; filter if necessary. The filtrate is now mixed with a solution of blue glucose (1 : 6 or 8) and laid aside for some time in the dark; filter again. The filtrate is now boiled and well stirred, when finely-divided bismuth is deposited, which must be filtered away, washed, and dried as rapidly as possible.

## ETHER FREEZING APPARATUS.

A SIMPLE and convenient ether freezing apparatus for microscopists has been described recently by W. Emil Boecker in the *Zeitschrift für Instrumentenkunde.* Following the principle of the Lewes and the Roy instruments, the ether spray is thrown on the under side of the object-plate instead of on the object itself.

The apparatus consists of a short cylinder (Fig. 1, A), closed by the plate (P), on which the object is placed for freezing. A metallic tube (*a*) drawn to a fine point penetrates the base of the cylinder, and another (*b*) its side. The vertical tube (*a*) is connected by rubber tubing with a small bellows, while the horizontal tube (*b*) is similarly connected with a glass tube which passes through the stopper of a bottle containing ether, reaching nearly to the bottom. When the bellows is set in motion, the current of air throws the ether spray against the plate (P), and the rapid evaporation thus produced soon lowers the temperature sufficiently to freeze the object. The ether vapor and the air escape through a series of holes in the side of the cylinder. A third tube (*c*) connects with a second glass tube that extends barely through the stopper of the bottle of ether, and thus provides for the admission of air into the bottle and for the escape of the excess of condensed ether. The cylinder is small enough to be received by the holder of the microtome.



## AMATEUR LENS MAKING.*

TO make an ordinary lens requires a certain degree of manipulative skill, but when compared with a fine job of filing, fitting, or even turning, it is easy, and there is a charm about making a nicely polished lens which is not found in metal working. The tyro should commence with small plano and double convex lenses, which he may mount singly or in pairs. After attaining a fair proficiency in making these, he may proceed to larger work, and afterwards, by coupling study with practice, he will be able to make fine work, such as the achromatic objectives of microscopes and telescopes, eyepieces, lantern objectives, &c.

The first thing to be done in the way of the preparation of tools for lens grinding is to make gauges or patterns with which to gauge the convexity of the grinding tools. These may be made from pieces of sheet brass, about $\frac{1}{32}$in. in thickness, the plates for gauges for convex tools being chucked on a plane board secured to the face-plate of the lathe, and the circular aperture turned out. The plate should be bevelled each way from the aperture, forming a knife edge, and it should be separated by a saw into two or four parts, according to the size of the lenses to be ground, as shown in Fig. 1. The radius of the circle so formed will be approximately the focus of a double convex of this curvature, and the diameter of the circle is approximately the focus of a plano-convex lens of the same curvature.

Gauges for concave tools or concave lenses are made by turning discs of brass with V-shaped edges, as shown in Fig. 2, and an instrument for shaping small concave grinding tools is shown in Fig. 3. It consists of a sharpened steel disc attached to or formed upon the end of a bar, and used as a scraper, for giving the final shape to the concave grinding tools. For grinding convex lenses it is well to have two concave tools like that shown in Fig. 4. This, as well as other grinding tools for small work, should be made of brass. Drawn brass is preferable, as it is usually better metal, and more homogenous than castings, and needs no external turning.

Having determined on the focus of the lens to be ground, the brass is chucked in the lathe, and hollowed out as nearly to the correct form as possible, the gauge shown in Fig. 2 being used from time to time to determine when the proper concavity is reached. The grinding tool is finally scraped with the cutter shown in Fig. 3. The counterpart of the concave tool shown in Fig. 5 is now turned as nearly to the gauge shown in Fig. 1 as possible,

---

and is finally ground into the concave tool with washed flour emery and water.

A tool like that shown in Fig. 6 is necessary for finishing small lenses. It consists of a cylindrical piece of brass, having a chamber turned in the end for the reception of a mixture of pure hard beeswax and fine rouge. This mixture should contain sufficient rouge to make it rather hard, but not so hard as not to yield under strong pressure.

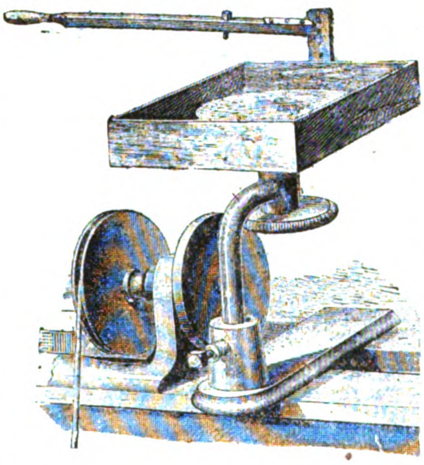
The glass for small lenses may be clipped from bits of plate (crown) glass and roughly shaped by means of an ordinary pair of pliers. It may then be cemented with pitch to the end of a round stick, as shown in Fig. 7. The glass is then ground on a common grindstone until it approximates the required shape. It is then polished with fine emery and water in one of the concave brass tools until a truly spherical surface is secured. It is then transferred to the other brass tool, and ground with fine washed flour emery until the surface is fine and entirely free from scratches. During the grinding, as well as polishing, the stick to which the glass is cemented must be turned axially, and at the same time its outer end must be moved about the prolongation of the axis of the grinding tool so as to present the glass to every portion of the grinding tool as nearly as possible.

The final polish is secured by pressing the smoothed glass into the wax in the end of the tool shown in Fig. 6, as the tool is revolved, and at the same time applying fine rouge and water from time to time. When the polish is nearly perfect the tool should be allowed to work nearly dry.

For a plano-convex lens the plane surface of the plate glass will answer very well for the plane surface of the lens, and the glass will be ground down as shown in Fig. 8. If the lens is to be double convex, the finished spherical surface should be cemented to the end of the stick, and the opposite side proceeded with as before described. There are two methods of finishing the edges of plano-convex lenses: first, by holding the plane surface in a concave tool charged with emery and water until the edge is bevelled to the required degree; and, second, by chucking the lens on the end of a spindle projecting from the lathe mandrel, and centring it while the pitch or cement which holds it is still warm. Then a piece of brass, which is concaved to conform nearly to the periphery of the lens, and charged with emery and water. This tool is held against the edge of the lens after the manner of turning. The lens will soon assume a perfectly circular shape, and may be readily reduced to any desired size. In making concave lenses the convex tools will be used, and the final finish will be given by a piece of silk cemented to the tool with pitch and charged with rouge and water.

For grinding larger lenses of longer focus an attachment like that shown in Fig. 10 will be required. It consists of a wooden box supported by a curved arm inserted in the tool-rest support. A vertical journal box passes through the bottom of the box, and contains a shaft, having upon its upper end a socket for receiving the grinding tool, and on the lower end a grooved wheel surrounded by a rubber friction band, which is revolved by contact with the face plate of the lathe. The speed of the wheel relatively to that of the lathe may be varied by raising or lowering the box support in the tool port.

The glass to be ground is cemented to the face of a flanged casting as shown in Fig. 9, and is held down to the grinding tool by the lever attached to the box. The tool for large work may be made of cast iron. The centre of the lens should be eccentric to the centre of the grinding tool, so that the lens will be revolved on the face of the tool. The point projecting from the lever enters a small cavity in the centre of the casting, to which the lens is attached, and insures an equal distribution of pressure over the entire surface of the lens.



Grinding and finishing a large lens is substantially the same as in the case of the smaller ones, the only difference being in the method of giving the final polish. In the case of a large lens, after the fine grinding, the tool is heated, covered with a thin coating of pitch, and a piece of thin broadcloth is pressed down on the pitch. The broadcloth surface is charged with fine rouge and water, and the lens is pressed down on it with considerable force as the tool is revolved. The cloth should be worked rather dry, and so much so at the end of the process as to offer considerable resistance to the rotation of the tool.

## THE ELECTRIC RAILWAY IN PHILADELPHIA.

THE electric railway soon to be constructed along Belmont Avenue, Philadelphia, will present the novel sight of cars running without any apparent propelling force, free from annoyance of noise, smoke, and dust. The motive power for the cars, which are to be run according to the Bidwell system, will be furnished from a station located somewhere on Belmont Avenue, outside the park. It could, if necessary, be carried over an indefinite distance. This system differs from other systems of electric railways in not passing the current through the rails. Guards made of lumber run along the inner side of the rails, and a broad covering projects toward the centre, leaving a narrow slot in the middle of the track. Beneath this cover, and parallel with the rails, properly insulated copper conductors of a semitubular shape are placed. The current is conveyed from the dynamos supplying the power through wires to the terminus of the railway, where connection is made with the copper tubes, and a current is thus sent through the whole length of the road.

To propel the car, a receiving dynamo or electromotor is placed in the centre of the car. Connection with the current is made by means of an iron tube passing down through the slot, with branches in either direction in the form of an inverted T. On the end of each branch a small wheel, so placed as to run against the copper conductors, completes the connection, wires being run through the tube from the electromotor in the car to the wheels. The electricity being passed through the circuit of the track, the operator has but to turn a lever to receive the current in the motor, which immediately revolves, and by an attachment with the wheels of the car propels it in either direction, according as the current is reversed or not. Through the reversal of currents the need of brakes is dispensed with. If necessary, the car can be brought to a sudden standstill, but the change can be effected as gradually as may be desired. There will, therefore, be no danger of running over persons on the track.

The avenue will be lighted with the same current by running wires from the tubes to the lamps, as in ordinary street lighting, while the cars will be illuminated by running a wire from the motor to the incandescent lamps in the interior of the car, the whole power coming from the single current supplied by the stationary engines some distance away from the track. If it is desired to heat the cars, another draught is made on the current by passing the electricity through some poorly conducting substance, as German silver, the electrical energy being thereby dissipated in the form of heat. These connections are made by means of switches, so that no current may be made through the branch wires when the light or heat is not wanted.

An important feature of this railway for the park is the utter impossibility of trifling with the conductors and receiving injury from a shock. They are placed beneath the board flooring near the rails, and the only opening is the narrow slot, more than a foot distant, the whole being concealed from view. The road will be about a mile and a quarter long, and ten cars, carrying from fifty to sixty passengers, will be run. To furnish the power for these, and to light both the avenue and the cars, about 100-horse will be required. — *Scientific American.*

## HERZOG'S PROCESS OF RAPID OIL BLEACHING.

THE *Organ für Oelhandel* describes the following process, invented by Dr. Herzog, for the bleaching and clarifying of oils and fats, both for domestic and industrial purposes. The solid fatty substances are treated in the same manner as those which are liquid. In order to prepare cottonseed oil, rape oil, as well as all fatty oils, for ulterior treatment, they are first mixed in large receivers with 2 to 3 per cent. of common salt, and then thoroughly stirred for five or ten minutes with 25 to 30 per cent. of cold water. After a rest of twenty-four to forty-eight hours a part of the impurities have been deposited at the bottom with the water and salt. The oil on the top is then drawn off and is thoroughly washed in another vessel with cold water by means of crank-shovels. After six to twelve hours the oil has again accumulated on the top and is drawn off for further treatment. This treatment with common salt is particularly useful in the preparation of fine culinary oils, but can also be employed with linseed oil, fish oil, &c. If an electric stream be conducted through the mixture during the mechanical treatment, the oil is at the same time bleached as the salt becomes decomposed under the influence of the electric current, and secondary combinations effect marked bleaching results. For many oils and fats which would otherwise become rancid and be spoilt, it is recommended in the above process to add 2 or 3 per cent. of bicarbonate of soda, which exercises a preservative influence.

In addition to the second washing with cold water in the second vessel, the oil can likewise be treated with steam, which is conveyed through the oil in a fine state of division. For cottonseed oil it is recommended for the process to be continued for five or ten minutes. By this treatment the rancid particles are removed while the slimy portions sink to the bottom. In place of steam, heated air may be sent through the oil, which is mixed with 25 to 30 per cent. of hot water. This operation should last five minutes, and might be repeated at intervals of two or three minutes. If the cottonseed oil, rape oil, or similar quality is filtered and left in store a certain time, a pure product is obtained of pleasant sweet taste and pale yellow appearance. For filtering it is recommended to use endless filtering paper, with which the sides and bottom of the filtering vessels are covered. After being used, pressed, and washed out the paper can be again used in flake-form in the preparation of filtering grounds. For the preparation of varnishing, burning, and lubricating oils the oil is mixed with 2 per cent. of common salt, dissolved in 15 to 20 per cent. of water, at 176° to 212° Fahrenheit, which is heated by steam introduced during the stirring. Then during the continued stirring there are added 1 to $1\frac{1}{2}$ per cent. of muriatic acid diluted in 15 to 20 per cent. of water, and steam is afterwards introduced at intervals of five minutes. In many cases Dr. Herzog considers very useful an admixture of permanganate of potassium, or chlorate of potassium, or bicarbonate of potash with muriatic acid. For 2cwt. of oil there are taken in the proportion of one-tenth pound of the last-named salts and $1\frac{1}{2}$lb. to 2lb. common salt.

## EXPERIMENTS WITH GELATINE EMULSIONS.*

### A New Developer with Sulphite of Ammonia.

I HAVE never been adverse to the advantages claimed by the advocates of the potash developer, especially when used for very rapid plates, or with very short exposures, and have even described a modified method of developing with potash, and published my own formula for it. Nevertheless, I now call attention to a new pyro developer with ammonia, and sulphate of ammonia, which has given splendid results with the ordinary commercial plates, equalling in every way negatives developed with ferrous oxalate, and even surpassing them.

The formula is:

| | | |
|---|---|---|
| A— | Pyrogallic acid | 10 parts |
| | Sulphite of ammonia | 30 parts |
| | Water | 100 parts |
| B— | Bromide of ammonium | 5 parts |
| | Water | 150 parts |

Immediately before use mix 100 parts of water with 4 parts of A and 4 parts of B. With this developer the image will appear quite rapidly. If it is desirable to prolong the developing process, 150 parts of water instead of 100 can be used. The negatives will be softer with a diluted developer, while more vigour, strength, and contrast is given by a few minims of a bromide of ammonium solution (1 to 10). Sulphite of ammonium developer makes brilliant and well-detailed matrices, representing perfectly the whites and high lights. They are of an agreeable, dark brownish colour, far superior to that obtained by a glycerine or potash developer. The use of the alum bath before fixing is admissible, but not necessary before fixing, but is wanted afterwards. No acid is needed with the alum. Pyrogallol, mixed with a solution of sulphite of ammonia, is more durable than with sulphite of soda, and prevents fogging of the plate more effectually than the corresponding soda salt. Sulphite of ammonia should not be used in combination with either the carbonate of soda of potash, with either of which carbonate of ammonia and the respective sulphites would be formed, resulting in but feeble action upon the bromide of silver emulsion, and rendering the negatives weak.

### Developer with Lime Water.

As early as 1877, Daranne recommended in "Progrès de Photographie," the use of lime water with pyrogallol, in developing bromide of silver collodion films: the process has, as far as the colour of the negative is concerned, proved also to be satisfactory with gelatine emulsion. Lime being sparingly soluble in water, a solution of sugar, one to ten, is prepared and shaken well, with lime in excess. The mixture assumes a violet or brown colour, and soon becomes turbid. With it I have obtained but very thin negatives, and for that reason can hardly recommend its use.

### Mixed Hyposulphite of Soda and Alum Baths,

so often favourably spoken of, should not at all be used. They fix much slower than pure hypo, separate constantly finely divided sulphur and alumina, and exhale an odour of sulphurous acid. The negatives assume a milky whiteness, which disappears when being varnished, and although it offers no obstacle to the printing, injures the appearance of the negative. When gelatine emulsion plates show such a marked tendency to frill as to expect their entire loss in a plain hypo fixing bath, they may be used to advantage, and possibly save and solidify a film, which otherwise might be destroyed. One part of ordinary fixing bath with one-half to two parts of saturated alum solution are proper proportions. Besides the tanning of film, the elimination of the fixing soda is retarded, which reduces the rapidity of diffusion, and prevents, consequently, the tendency to form blisters.

### Transforming Silver Deposits into Chloride of Silver.

To remove yellow stairs from negatives, as recently recommended by L. Betitsky, is nothing new. A method of using potassium bichromate and hydrochloric acid for the same purpose, and as a toning bath for bromide of silver, gelatine emulsion plates has been recommended by Eder and Toth in 1882.

---

* By Dr. J. M. Eder in *Correspondenz.*

## OIL ON TROUBLED WATERS.

THOSE of our readers who are interested in the question of the effect of pouring oil on the waves, will be glad to learn that the United States Hydrographic Office has been collecting data to determine under what circumstances its use is most efficacious in diminishing the danger of breaking seas during gales of wind. Masters of vessels are requested to make experiments in this matter whenever the opportunity occurs, and report the results to one of the Branch Hydrographic Offices, or directly to the Central Office at Washington. When sufficient data have been collected a pamphlet will be issued giving such directions in regard to the use of oil as the common experience of seamen may determine to be the best. The following accounts have been received lately:—Capt. R. S. Thompson, ss. *Sacrobosco*, reports using oil in 1880, and twice during the month of February, 1885. In each instance, after getting his ship before the wind, he put over oil bags with the best results. In the first case the engines were slowed so as not to lose too much to leeward, and it was proved clearly that with the use of oil it was not necessary to run as fast as is generally supposed. Captain Smith, of the English barque *Emma*, used refined petroleum during the gale in which his vessel was abandoned. He found it entirely useless, although barrels of it were emptied to windward, and seven or eight bags of it were towed alongside. About five gallons of crude turpentine or pine oil was used with good effect as long as it lasted. Captain Geddes, of the s.s. *Erato* in February, 1885, instead of heaving-to during a favourable gale, concluded to run. He shipped some very heavy seas, which did great damage until the oil bags were put over, when the ship ran comfortably with the decks perfectly dry. Captain Daniel Thomas, of the British barquentine *Corisande*, in January, 1885, during a gale, while lying-to, was boarded by a heavy sea which washed one man away and disabled the vessel, which lay in the trough of the sea. Men were stationed immediately to pour oil overboard until bags could be prepared and the vessel secured. When this was done she was easily got before the wind and ran very comfortably. Captain Johnson, of the English steamer *Emerilda*, reports using oil bags with excellent effect, during a heavy north-west gale, on his last voyage from Port Royal to Liverpool. Captain Moore, of the British barque *Siddartha*, says that during the last four years he has frequently used oil bags when hove-to or running, and has invariably found they made a wonderful change in the nature of the sea. His system is to fill a coarse bag with oakum, thoroughly saturated with oil, and to hang it over the weather bow, if hove-to. or to the bumkins, if running. Chief-officer John Matson, of the English steamer *Edinboro'*, in 1881, while lying-to in a mountainous sea in the Bay of Biscay, placed two oil-bags overboard forward with the best results, the oil effectually preventing the sea from boarding the ship. Captain Scott, of the English s.s. *Briscoe*, during a recent passage from Baltimore to London, experienced heavy gales from W.N.W. to W.S.W., with high seas sweeping over the ship. He filled two canvas bags with oil and towed them over the stern with excellent effect, as they prevented the seas from boarding the vessel. Captain Mumford, of the British s.s. *North Anglia*, in October, 1884, during a hurricane, had his main wheel gear carried away, and was obliged to steer aft. After the men had been washed away several times, he tried oil and had no further trouble. Again, in February, 1885, while hove-to, he poured oil through a pipe on each side of the forecastle. Oakum was put loosely into the pipes to prevent the oil running too quickly. After commencing the oil no dangerous water was shipped. Mr. G. Foster Howell, of New York, sends a very interesting account of the use of oil while off the Horn in the ship *Cavalier* in 1876. The ship had been run too long, and heavy seas were constantly boarding her. At last one more powerful than the rest rushed upon her with awful violence and started the deck. At the writer's suggestion oil bags were towed overboard with about 25ft. of line, one on each quarter and one amidships. "No sooner had the oil commenced to leak than the sea ceased to boil and rage, and the waves became so harmless that they no longer broke upon us."

## SCIENTIFIC NEWS.

FROM Dun Echt Circular, No. 94, we learn that a new comet was discovered by Mr. E. E. Barnard, of the Vanderbilt Observatory, Nashville, Tennessee, on July 7. The comet was observed at Harvard College on July 9, 17h. 17m. 31s., G.M.T., when it had R.A. 17h. 17m. 48·4s., and S. Dec. 6° 1′ 8″. The daily motion was — 2m. in R.A. and 35′ towards the South. It is described as not more than 1′ in diameter, 11th mag., or fainter, and as having some central condensation, but no tail. The comet was sought at most European observatories on Saturday and Sunday evenings; but the only observation of which intelligence has been received was made at the Strasburg Observatory 57 minutes after midnight on Saturday, the observed place being R.A. 17h. 14m. 24·3s., N.P.D. 97° 2′ 31″. At Greenwich the comet was traced with the help of the $12\frac{3}{4}$in. equatorial about 10h. 30m. on Saturday, but clouds intervened before an observation could be secured.

Prof. Adams's report to the Senate of Cambridge University was issued last week, and shows that a large amount of routine work and many special observations have been undertaken during the year ending May 26th. The observations of Clock Stars and those of Polaris are completely reduced, and the mean places for January 1st obtained up to the end of 1884. The true apparent place of all the other stars observed in 1884 is also obtained both in R.A. and N.P.D. As regards the observations of former years:—The mean R.A. and N.P.D. of the Zone Stars are obtained up to December 12, 1877, and the true apparent R.A. and N.P.D. to the end of 1882, and the reductions are far advanced in 1883. The reductions from mean to apparent place at date are calculated to the end of 1882. The means of transits and microscope readings are deduced up to the present time. The intervals of R.A. wires used in the reductions for 1884 were obtained from 63 observations of Polaris made 1884, January 18—July 10 (1), by taking the mean of the intervals for Polaris and the mean of the declinations, and using the formula $\sin. E = \sin. P \cos. \delta$; (2) by deducing the equatorial intervals from each individual observation, and taking the mean of the results. The intervals by the two methods almost exactly agreed.

Nos. 2665-6 of the *Astronomische Nachrichten* contain a complete list of recent determinations of cometary orbits by Prof J. G. Galle. It appears that five comets passed perihelion in 1880, eight in 1881, three in 1882, two in 1883, and three in 1884.

It is rumoured that the professorship of biology at South Kensington, resigned by Prof. Huxley, will be superseded by the creation of two lectureships of £300 a year each.

Dr. Boverton Redwood, retired as Emeritus Professor of Chemistry to the Pharmaceutical Society, has been succeeded by Mr. W. Dunstan, of the University Museum, Oxford, as professor of chemistry.

Mr. E. Thurston, curator of King's College Anatomical Museum, has been appointed director of the Central Museum at Madras.

The excursion of the Geologists' Association will this year be to Belgium, the members meeting in Brussels on August 10, and proceeding the same evening to Charleroi. M. Ed. Dupont, Prof. A. Renard, Dr. E. Purves, and Prof. J. Gosselet will act as guides. The excursion will last five days.

The Essex Field Club is desirous of founding a local museum, and proposed to establish it in Queen Elizabeth's Lodge at Chingford; but a "high official of the Corporation" objected, and the club, which has done excellent work, especially in connection with the natural history of the Forest, is in want of a suitable locale and a habitation for the collections, which would no doubt speedily increase if a museum were established.

The study of natural science is prosecuted with vigour in New South Wales, and the Hon. William Macleay, a member of the senate of Sydney University, and president of the New South Wales Linnean Society, has established and endowed four fellowships of £400 a year each, for the encouragement of study and research in natural science. The fellowships can be held only by graduates of the university who are without other lucrative employment, and are actively engaged in research. They are renewable annually, in order, we suppose, that the appointment may approximate as nearly as possible to "payment by results," or, as has been suggested, to give "an opportunity for correcting any abuse."

At the meeting of the Royal Society of South Australia, on June 2, Mr. W. Howchin, F.G.S., exhibited a specimen of Astrorhiza angulosa as a fossil found in the Miocene strata of Victoria. The specimen was stated to be of more than ordinary interest, inasmuch as it was the first instance in which the genus had been found in the fossil condition in the recent slate. The species submitted was very rare, having been hitherto known to occur only at two localities—one of these being at a *Challenger* station to the east of the Azores, at a depth of 1,000 fathoms; and the other at a point in the North Atlantic, dredged by the *Porcupine*, at 630 fathoms—where only a single specimen was taken. There are five species in the genus, but with the exception of a single specimen of an allied species taken by the *Challenger* off the Cape of Good Hope, the genus is only known as a North Atlantic type. The species discovered in the Victorian rocks is one of the rarest; its occurrence, therefore, in the fossil condition in the Australian tertiaries is a matter of some interest. The speaker stated that his researches with regard to the microzoa of the Australian formation led him to believe that many of the rarer arenaceous forms of foraminifera recently discovered in the deep seas, and which have been so beautifully illustrated by Mr. H. B. Brady in the "Scientific Results of the *Challenger* Expedition," occurred as fossils in Australian geology from the Cretaceous formation downwards.

At the same meeting Mr. C. L. Wragge read a portion of his paper entitled "Scientific Results of a Voyage in the *Maronoa*," dealing with that part of the voyage between England and the Suez Canal. Some singular facts in connection with winds and tides have been discovered by means of the bottles which Mr. Wragge threw overboard with requests for particulars of where they were found and when.

Some important telephone experiments were made between Uxbridge and Liverpool last week, on one of the new lines of telegraph wire recently erected. The distance is about 200 miles, and it was doubted whether satisfactory results could be obtained in this country over such a length of wire. The Gower-Bell transmitter was employed, and the tests applied satisfied the experts that it would be possible to speak with sufficient clearness over double the distance. Two line wires were used.

Prof. E. Stebbing, of Paris, informs the *British Journal of Photography* that "a great hope is felt here that MM. Hembert and Henry have succeeded in a practical manner in producing hydrogen from water by decomposing steam." The latest experiments of these savants have, it seems, been highly satisfactory. Steam is generated, and it is then superheated to "dissociation" by making it pass through a retort filled with incandescent coke. The steam is decomposed, and two gases are formed—hydrogen and carbonic oxide—in equal volumes. This mixture passes into another red hot retort, where a jet of steam mixes with it, and acts upon the oxide of carbon, and transforms it into carbonic acid. The hydrogen produced by this second operation added to the other makes about 3,200 cubic metres per ton of coke. The hydrogen is purified by passing it through lime-water—just, in fact, as is described in most textbooks of chemistry, the process being that of Deville and Debray, who seem to have been forgotten by their own countrymen, MM. Hembert and Henry. Prof. E. Stebbing thinks that, sooner or later, "we shall have a purer and more uniform gas to light up our dwellings."

The Cunard liner *Etruria* has accomplished the quickest eastward passage of the Atlantic, having arrived off the Fastnet on Friday last in six days, seven hours, and forty minutes from New York. Unfortunately fog came on, and her time to Queenstown was six days thirteen hours forty-five minutes. It is said to be the fastest passage on record to the Fastnet, but scarcely, we should think, comes up to expectations. The *Umbria* and the *Etruria* ought both to do better than that.

The *Arawa*, of the Shaw-Savill-Albion line, reached Plymouth last Sunday, thirty-six days seven hours out from Lyttelton, New Zealand—the fastest passage on record. This voyage is the quickest ever made round the world. The *Arawa* left Plymouth on March 28 and arrived in New Zealand on May 7 (40 days); she left Lyttelton on June 6 and made a splendid run of 20 days to Rio, and having coaled, left again on June 27—the actual steaming time on the run home being only thirty-five days thirteen hours ten minutes. Her steaming time for the round voyage was 74 days!

A statue is to be erected in the Conservatoire des Arts et Métiers to Leblanc, the French chemist who introduced the soda process which bears his name. The proposal has been a long time before the world; but by the aid of the principal soda makers of Belgium, Germany, and the United Kingdom, sufficient funds have at last been collected, and the statue will be placed near that of Denis Papin.

Dr. G. Brown, of Edinburgh, in company with Drs. Roy and Sherrington, has left for Spain, to carry on further investigations upon the etiology of cholera.

The fifty-second annual report of the Royal Cornwall Polytechnic Society is, as usual, full of a variety of useful notes on new inventions, to which prizes have been awarded, and of papers of special interest, mainly to miners.

The *South Wales Press* announces the death in London of Mr. F. T. Williams, for 25 years manager of the lead and silver works, Llanelly, and of whom Col. Ross spoke in these columns recently "as an old Freiberg student, and a man of first-rate ability."

**The Exploration of Africa.**—Last week an address was delivered in the Merchants' Hall, Edinburgh, before the members of the Scotch Geographical Society, by Mr. Henry O'Neill, Her Britannic Majesty's Consul at Mozambique, on the subject of African exploration. Sir Donald Currie occupied the chair. Mr. O'Neill, in the course of his address, said that the ground he had passed over in Africa had been done in 12 journeys, and had occupied nearly six years. He had covered about 4,000 miles, and nearly one-half of these had been over previously unbroken ground. Briefly, the chief results of those journeys had been to open up three new routes between the Nyassa district and the coast:—1, between Mozambique and Lake Shirwa and Blantyre; (2) from Blantyre to the Portuguese coast settlements of Angoche and Parapato; (3) from Quillimane to Blantyre. The Nyassa might now be reached by the longest of the three routes opened up by him in 30 days, and that from Quillimane to Blantyre in 14. The country was well populated, food was fairly abundant, and the people were peaceable, helpful, and industrious. There was no reason whatever that any or all of the three routes he had laid down might not be constantly traversed by Europeans and become most valuable channels for the development of the trade and agricultural riches of the country. In his journeys he had been fortunate enough also to discover three minor lakes, one, Lake Lidedi, which was just south of the Rovuma, and close to the Lake Nangadi, of which Livingstone first heard as he passed up north of that river when upon his last travels. The others were Lakes Amaramba and Cheuta, which had their outlet in the River Lugenda. About 5,000 observations had been taken by him to fix the positions of 57 of the most conspicuous points and principal features of the country, and nearly all these observations had been reported to be completely satisfactory by the scientific staff of the London Geographical Society.

# LETTERS TO THE EDITOR.

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. PASSMORE EDWARDS.

**** In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

## THE POST OFFICE AND THE PRESS—MAKING HAZE WHILE THE SUN SHINES — LUNAR GLACIATION — MAGNETIC DECLINATION IN YORKSHIRE—THE NEW TIME—THE "NAUTICAL ALMANAC"—WHAT IS "CREATION"? — POWER FOR AN OPERA-GLASS.

[24472.]—AN idiotic piece of Post Office red-tape has just been brought to my notice in connection with these letters of mine. Being, of course, intended to be printed, they go by book post, under paragraph 2 of the regulations on page 3 of the "Official Guide." I learn, however, from our editor, that, while they reach the office between 8 and 9 a.m. on the Saturday morning if posted as letters with a penny stamp, *they are delayed until noon* if they only bear a halfpenny one. Paragraph 5 of the regulations to which I have just referred does say, it is true, "When, owing to an unusually heavy influx of letters, books, &c., the transmission or delivery of the letters would be delayed if the whole mail were dealt with indiscriminately, book-packets may be kept back till the next despatch or delivery," and it is not difficult to see that a number of octavo volumes weighing 3lb. or so a-piece might delay the delivery. Why, though, a letter—for so it is—in an open envelope, weighing perhaps a quarter of an ounce, should be detained, simply because it legally has a halfpenny stamp instead of a penny one upon it, I wholly fail to see. I suspect that this is the doing of some under-strapper in the department, who thinks by such conduct to drive everybody into the use of penny stamps for literary MS.; much as some of the idiots of railway managers, in their frantic efforts to compel everyone to travel first-class, drive their customers out of the second—into the third! This most trumpery system of conferring a seeming boon with one hand, only to take it away with the other, is wholly unworthy of a Government office which is the source of a really considerable annual addition to the revenue.

Every one, and certainly every astronomer, must be familiar with the fact that the odd and remarkable haze which has now perpetually surrounded the sun for more than two years still persists; in fact, as I have said on a former occasion, the observer has only to hide the orb of the sun itself with his hand to see this strange pseudo-coronal glare in his immediate neighbourhood, and to note where the blue sky proper actually begins, and how comparatively sharp is the line of demarcation. I am anxious to emphasise this because news reached Holland a week or two ago of a violent eruption of the volcano Smerdu in Java, and, in fact, of great volcanic disturbance over the whole of the west of that island; and that most valuable and trustworthy body, the "Krakatoa Committee" will almost certainly point to this circum-solar haze as the result of this last eruption.

I may say, very briefly, with reference to letter 24418 (p. 389) that I cannot myself understand aqueous vapour being transported by actual translation. My own view is that if any heated lake or sea emitted steam, this would be diffused in the atmosphere generally, and by no means condensed and deposited in the form of snow or ice in the immediate neighbourhood of the point of its genesis. I shall be very curious to hear what Professor Darwin thinks of Mr. Peal's theory.

Premising that magnetic declination is an element not susceptible of rigid predication, I may say (in reply to query 56952, p. 397) that at Hull (the nearest point to "Streetgate's" station at which it has been determined) the needle at present points 18° 21′ west of north. In the year 1881 the magnetic declination was 18° 47′ in the same locality.

I should like to make two remarks with reference to letter 24445 (p. 411). The first is that I did not (*loc cit.*) adduce the case of the commencement and conclusion of a solar eclipse, before and after noon of the same civil day, as presenting any special difficulty. All I did say (in reply to Mr. Hopkins), was that it was cognate with the one which exercised him in connection with the phenomena of Jupiter's satellites. In the second place, I have never advocated the adoption of the new mode of reckoning time until the alteration shall have been made in the *Nautical Almanac.* The hideous muddle it would introduce into the calculations made by the Mercantile Marine would, in all human probability, lead to grave disaster. How far such alteration is probable Mr. Franks can judge as well as I can. No more conservative institution exists on the face of the earth than that which has its headquarters in Verulam-buildings. Look at the Tables of Jupiter's Satellites, the grossly erroneous data given of the relative dimensions of the Saturnian System, and (until quite recently) the Ephemerides of Uranus. When very strong public pressure is applied from the outside somebody wakes up, and by the kind aid of the Americans, or the French, rectifies what is most glaring—and then goes fast sleep again.

I cannot answer the query propounded by "H. B. F." in letter 24452 (p. 412), for the simple but sufficient reason that I have not the most distant idea what "selective creations" are. Your correspondent must forgive me for expressing the opinion that he uses the word "creation," as a great many people employ the one "electricity"—i.e., as a quasi-scientific way of hiding the fact that they know nothing at all about the phenomenon they adduce it to explain! Creation, if rigidly defined, means the bringing into existence *ex nihilo.* A man does not "create" a new type of clock by adding a striking-train to the going movement of an old one. Moreover, unlike "H. B. F.," I do not profess to "account for the first appearance of such abnormals." All I can certainly predicate is that there seems to be a tendency to variation in Nature. Whence it arises, I am in humble ignorance.

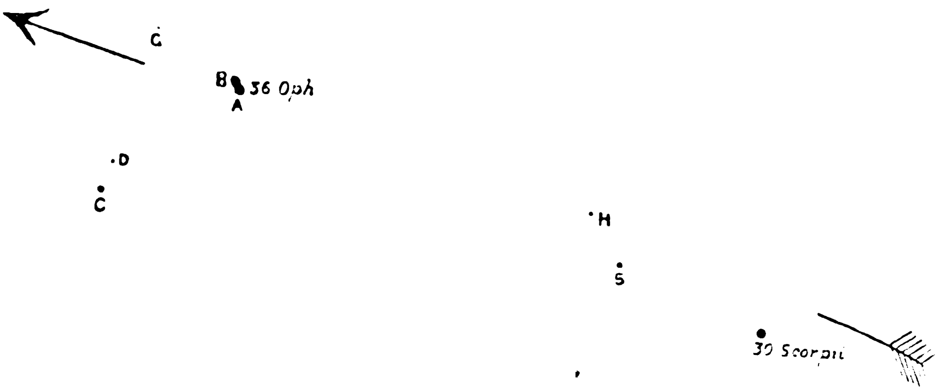
I reply to the question asked by "Experience" (letter 24462, p. 413) because it would be discourteous not to do so; but it really seems what our Roman Catholic brethren call "a work of supererogation" to say that it is a most utter "delusion that increase of power in an object-glass of given size can be obtained without sacrifice of light or field"—always, of course, supposing that (as Mr. Nelson points out in letter 24460) the emergent pencil is not bigger than the pupil of the eye. As for the power most suitable for *opera*-glasses, I regard 3 as ample, always supposing that you wish to get a general view of an actor or actress, and not to examine him—or her—piecemeal. For outdoor work, though, a higher power tells wonderfully.

**A Fellow of the Royal Astronomical Society.**

## DOUBLE STARS—36 OPHIUCHI—53 OPHIUCHI.

[24473.]—It has long been known that 36 Ophiuchi (itself a binary pair) is physically connected with 30 Scorpii, notwithstanding their immense distance, the large annual proper motion of both being about 1·230″ in the direction of 203·0°, and there is an intermediate star mentioned in "Celestial Objects," which was thought by Flammarion to partake of the same proper motion. I have observed the group very carefully during the past month, to determine this point if possible; but cannot say the result is quite conclusive. There is a considerable discrepancy between the MS. and "Cycle" diagrams of Smyth in 1835, Flammarion's drawing in 1877, and the apparent place of the star. Smyth represents it in the "Cycle" and MS. diagram, from which it was written as decidedly S. of the line joining 36 Ophiuchi and 30 Scorpii. Flammarion shows it in 1877 about 20″ N. of the line, and the present place of the star appears to be almost exactly between A of 36 Ophiuchi and 30 Scorpii; if anything, a little N. It is difficult to understand how such a difference can have arisen, for the star is most conspicuous with 120, which includes the whole field, thus rendering comparison very easy; it was rated at about 11th mag. The star G discovered by Challis in 1839 is no longer in the place described in the Cycle, viz., "where lines through A B—C D meet," a change no doubt due to the proper motion of A B, and which would seem to indicate it is not connected with the system. There is a very faint star H a little *s.p.*, the "stranger" S., which probably is one of the other stars referred to in Challis's note in 1839. This would form an excellent point for a series of measures of the P. A. and Dist. of S, when any change (supposing S to be connected with 36) would speedily be detected. The following are some of the principal measures of the group:—

A B = 202·0° 4·2″
A C = 306 0° 198·1″
A and 30 Scor. 75·0° 725·2″



C is about 8 mag., and D 10·5, S 10·3, G 10·8, and H 11·0 of Σ.'s scale. There is also another glimpse star in the group, but it is too near the limit of my aperture to hold steadily. For the above measures and tracings of Smyth's and Flammarion's diagrams, I am indebted to the kindness of Mr. Sadler, at whose suggestion the object was looked up; it requires very careful watching. and opportunities must not be lost, as its great S. declination renders it peculiarly liable to be obscured by mist and radiation from the earth. Since sending my note on 53 Ophiuchi, I find there is a slight error in it, the star mentioned as "N. a little *f.*" being really *n. p.* 53. There are six more small stars in the field (found since the drawing was made), and a faint *comes* to C (the 8th mag.) at about 40″± constituting it a double star in the same sense as 53 itself.

**Kenneth J. Tarrant.**

Letchford House, Pinner, 7th July.

Erratum.—I find in to-day's issue that an error has been made in line 11, of letter 24440, which renders the sense rather obscure, a plus sign having been inserted instead of the word "and." It should read "and *s.p.* AB at about 75″ ±."

July 10. **K. J. T.**

## DOUBLE STARS—TO MR. GAUDIBERT —THE TERRESTRIAL TELESCOPE.

[24474.]—The pair in Corona Borealis, you mention in letter 24439, p. 410, is apparently new, and is an interesting object. It is evidently Bode (Lalande 28500), and its approximate place, brought up from Weisse's "Bessel" to the commencement of the present year, is

XVh. 31m. 51s. + 36° 5·3′.

It is rated 7·5 mag. by Argelander in the "Durchmusterung," and the mean of Bessel's two observations gives the same value; Bode and Lalande call it 7 mag. It is strange that so bright a pair was missed at Dorpat and Pulkova, and by modern double-star observers. Have you not rather overrated the brightness of A, as the star does not appear in any naked-eye catalogue? I have endeavoured to find some recent meridian observation of it, for the purpose of ascertaining its proper motion, if any exists, but have failed to find any modern determination of its place in any prominent catalogue. There is a little difference between the respective declinations of Lalande and Bessel, but probably no greater than would be accounted for by the probable errors of the two catalogues. The pair Σ. 1959: 8·7, 10·2 mag.: 241·1°: 1·7″, is 1m. 35s. preceding, and 1° south of your pair.

The following are some of the most recent observations of the stars you mention:—

ζ Boötis. Eng. 300 9°: 0·670″ (seven nights): 1883·3.

η Coronæ. 173·9°: 0·61″, 1885·5; calculated from Doberck's elements.

Gl. 435 (O. Σ. 273). De. 110 6°: 1·0″: 1871·1; distance increasing.

Gl. 487 (Σ. 1944). Hall 333 9°: 1·25″: 1879 5.

Gl. 488 (O. Σ. 296). Seagrave 312 5°: 1·47″: 1882·4.

Gl. 510. (O. Σ. 306). De. oblong in 60°, but not easily measurable. 1865.

Gl. 522. (Σ. 2049). Distance constant at 1·1″.

Gl. 525. (O. Σ. 313). Pe. 151·6°: 0·99″: 1883·5.

Gl. 530. (O. Σ. 315) β. 166·4°: 0 97″: 1881·6; Pe. 161·7°: 1 00″: 1883·5.

Gl. 536. (O. Σ. 321). Probably no change since O. Σ.'s measures in 1848.

Gl. 566. (O. Σ. 338). Pe. 20·1°: 0·62″: 1883·5.

Gl. 572. (Σ. 2275). De. "L'Angolo di Σ. corrisponde, ma la coppia non è misurabile." 1866.

Gl. 494. (O. Σ. 298). Schiaparelli's angle agrees well with the one computed from Dolgorukow's elements for that epoch, but, of course, the angle is not 7·5° *now.* It is not 130° either, in which direction you observed the doubtful elongation. You showed this object again, with higher powers than 370 or 208.

You will find the following pairs in Cygnus beautiful objects, and fair tests of the defining power of your telescope and eye on moderately close unequal pairs. All the small companions seemed blue (in two cases deep blue) to me some ten years ago when I looked at them, but I have not seen them since. The places are for 1880, and the stars are prominent ones, though not in Webb. The mags. are in Σ.'s scale:—

B. A. C. 6959 Cygni. (A. C. 17). XXh. 9m. 10s. + 51° 6′. 6·0, 11·0.

60 Cygni. (O. Σ. 426). XXh. 57m. 0s. + 45° 41′. 5·4, 9·4.

44 Cygni. (A. C. 18). XXh. 26m. 26s. + 36° 32′. 6 3, 11·0.

75 Cygni. (A. C. 20). XXIh. 35m. 28s. + 42° 43′. 5·2, 10·5. A distant 9 mag. is *h* 1678.

P. XXI. 215 Cygni. (β. 167). XXIh. 31m. 1s. + 29° 31′. 7·0, 11·3.

The distance of the widest pair of the five, B.A.C. 6959, is only 4·0″. The pair of somewhat similar character (Dawes 13), alluded to in "Celestial Objects" under the head of δ Cygni, is 12′ *south*, and not north of that pair, as printed. It is 15 seconds of time preceding δ.

Mr. Nelson, "Montmartre," and others, writing about the aperture of telescopes for terrestrial use, will find a short article by Prof. Holden on the "Light of Telescopes used as Night-glasses," in the *American Journal of Science and Arts* for August, 1881, of interest. It refers to some observations on distant terrestrial objects made with the 15½in. refractor of 20ft. focus in twilight and by night. **H. Sadler.**

## THE DAYLIGHT OCCULTATION OF ALDEBARAN.

[24475.]—This occurrence was observed here under the most favourable conditions; the sky was almost cloudless, and the sun shone with all its summer brilliancy. Aldebaran was bright and clear, and the moon's limb well defined, the star being snuffed out instantaneously without the least hanging on the limb or lingering light. At the reappearance, the moon's dark limb was invisible, but the driving clock carried the telescope steadily during the interval, and the star flashed out near the centre of the field, shining at once with its accustomed brilliancy. The power used was 64 on the 6 4/10in. Merz achromatic telescope and the times as taken by the sidereal chronometer by Dent were:

| | | | h. | m. | s. |
|---|---|---|---|---|---|
| 1885. | July 9th. | Disappearance | 6 | 20 | 25 |
| | | Reappearance | 7 | 9 | 44 |

The chronometer error had been determined by star transits the previous evening.

**C. Grover,** Assistant Observer to C. E. Peek, M.A., F.R.A.S.

Rousdon Observatory, Lyme Regis, Dorset.

[24476.]—The occultation of Aldebaran by the moon in the forenoon of the 9th inst. was well seen here in bright sunlight. The sky was very clear, and about 11 a.m. I observed Aldebaran shining brightly near the illuminated edge of the waning moon, which had southed at 9h. 14m. a.m. The reddish-colour of Aldebaran was very noticeable, and, as the moon approached the star, the latter appeared more brilliant by comparison—it disappeared instantly on contact. There did not seem to me to be any projection on the moon's disc, as is said to have occurred previously. Time of disappearance at Greenwich stated to be 11h. 23m. 26s. The dark portion of the moon was quite invisible; but using a somewhat low-power eyepiece, I had no difficulty in placing the estimated position of emersion in the centre of the field of view, shortly before the calculated time, and had the satisfaction of noting the sudden reappearance of the star. Telescope used: A 6½in. Calver, silver-on-glass, with an eyepiece of a power of 60. **A. H. S.**

Southampton, July 10.

## 100 TO THE INCH ON TELESCOPES

[24477.]—There seems a veritable paradox about telescope powers. Bearing in mind the conventional 100 to the inch, we yet know that Herschel applied to his 6¼in. reflector powers as great as 6,000 – nearly ten times the limit by the rule just referred to. Kitchener, in his "Companion to the Telescope," which I have by me, speaks of some reflectors of his, 7in. in aperture, "magnifying from 50 to 2,000 times." Further on he relates an observation of Polaris through a 3⅝in. o.g. with powers up to 700, and even 1,123, and with the latter "the small star was still visible." Advising students as to a battery of powers for a 2¾in. o g., he mentions 300 for close doubles, and says that an optician made him one of 425, with the performance of which he was quite satisfied. Were there "giants in those days," or what is the explanation? I appeal to "F.R.A S." and Mr. Franks.

**Arthur Mee.**

## 100 TO THE INCH.—TO MR. SADLER.

[24478.]—Allow me a few words of explanation in reply to those correspondents who are at issue with me on the question of 100 to the inch of aperture. To begin with, I never said that my illustration was intended for *planets*, or other objects having a sensible disc—indeed, I should have thought that, in speaking of 100 *to the inch*, no one would have supposed it to be meant for anything but *stars*. Confined to the latter objects, my remarks were justified by the facts of the case. And, with regard to what "An F.R.A.S." says concerning a 2¼in.—on which he frequently uses *more than* 100 *to the inch* on lunar craters, Saturn's ring, &c.—well, all I can say is, I should like to see *Saturn* with such a miraculous glass. I have a lingering suspicion that with such an abnormal magnifying power and so little light, I should see no detail at all.

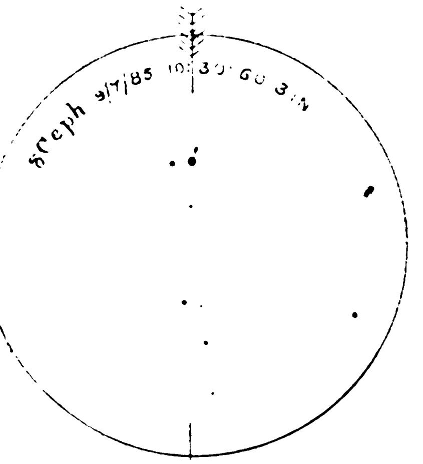
I am obliged to Mr. Sadler for his remarks on the red star B. Add 27. As the mags. of 10, 11, and 12 Gem. are all below 6 in the B.A.C., they were not included in my observations during 1877-8. I find an entry, however, of B. 607 (P. xxii. 36) Lacertæ, as follows:—"Oct. 17, 1877 : 5·5m. : bright yellow : < 1 Lacertæ." I fancy that $\alpha^2$ Cancri was added by Mr. Sadler himself in the appendix to "Cel. Objects"; and, therefore, in reading the proof, I should take his accuracy in such matters for granted. The date of my observation of 70 Ophiuchi, mentioned in "Cel. Objects," is July 29, 1876, with 5in. o.g. A recent observation of the same object was made on June 3, 1885, with the 11¼in. speculum, thus:—"70 Oph.: yel., deeper yel.: ang. lat. 40° ±: very neat."

**W. S. Franks.**

## $\delta$ CEPHEI—VEGA.

[24479.]—I am indebted to Mr. Sadler for kind answers to inquiries so long since as December 5, 1884. Will he please accept my best thanks, and may I now beg a little more information from him?

$\delta$ Cephei.—The field, as seen with a power of 60 on a 3in. Wray, presents a most interesting view. I am not, however, concerned so much with the primary pair (though "Celestial Objects" says, "especially fine, somewhat like $\beta$ Cygni"), as with the coarse *n.p.* triple, shown in the following diagram:—



I should be very much obliged to Mr. Sadler if he would kindly give me some details of this *n.p.* triple from the list of Herschel or Struve, the magnitudes, P.A., and distances.

Vega.—I believe Mr. Sadler is of opinion that the *comes* 159° 43″ is variable. It seems to me more distinct now than the *n.f.* and more distant one, 40° 140″.

I suppose, generally speaking, this latter is the plainer of the two; but with 240 on 3in. Wray the former one has of late seemed more distinct to me. Am I in some error here, or is my observation worth anything in corroborating the statement of variability? Is the 140″ 40° *comes* variable too?

July 10. **H. D.**

## SUSPECTED VARIABLE STARS IN FIELD WITH B 464—STAR MAGNITUDES—$\pi^1$, $\pi^3$, &c., ORIONIS—60 LEONIS—B 135—B 148—B 437—B 448—$\phi^2$ AND $\upsilon^1$ CANCRI—STARS IN FIELD WITH $\gamma$ LEONIS—B 607—ALCOR.

[24480.]—In the first place, I would like to be allowed to correct two small misprints which have crept into letter 24390 (p. 364). In second par., line 8, "$\beta$ 212," should be "B 212"; and in sixth par., third line from end, "$\beta$ 279" should be "B 279."

In speaking of the beautiful red star B 464, Birmingham says, "forms preceding angle of a beautiful triangle containing seven principal and several smaller stars." When observing B 464 on the 28th August last, I found that although the triangle *was* composed of seven stars, one of them was much fainter than the rest. This star was situated in the south face of the triangle, and is the next star *following* B 464. On the 7th November I confirmed my previous observation of this star, and made a rough sketch of the field. On the 9th ult. I saw the field again, and made the following rough sketch. The stars are numbered in order of brightness, 1 being B 464 itself. The stars which, so far as I can make out, make up the "triangle," are those numbered 1, 2, 3, 4, 5, 6, 9—for 8 is too far to the right to form part of the *n f.* face, and 7 is not in this triangle at all; 9 is the star referred to above. It was found to be much fainter than any of the other stars; in fact, the "triangle," the figure of which was obvious when the field was looked at, was only made up of six stars. If Birmingham did not, which I do not very well see how he could, reckon 8 as one of the triangle itself, and if the seventh star was 9, the latter must be variable, for it is in no sense one of the "principal stars" now. The star numbered 5 may also be variable, for I notice that in the sketch made on Nov. 7 last I have numbered it 3. Perhaps some of those who have made observations upon this exceedingly beautiful group of stars may be able to furnish further particulars. The whole region is well worthy observation.

Mr. Espin's letter in "Ours" for June 12 (24339, p. 322) is very interesting, and I would like to make one or two remarks upon it. Would Mr. Espin give some further particulars respecting Heis 121 Persei, and the suspected confusion between it and another star by Heis and Peirce. Objection may, I think, be taken to an expression which appears in the first paragraph of Mr. Espin's letter, assuming it not to be a misprint. He says, "which is a bright 6·0." The expression "a bright 6 magnitude" is quite correct, for the phrase "6 mag." is necessarily indefinite; but there can be no such thing as a "bright 6 0," or a "faint 6·0" either, for "6·0" has an exact and definite meaning. No star rated "6 0" can be supposed to be brighter or fainter than another rated the same, unless the scales employed in the two estimates be different. Again, as to $\pi^1$ Orionis, I would like to know how Mr. Jackson made his observations, that he can give them with such precision to the second place of decimals. It would be well if observers would content themselves with giving the magnitudes to the first place, for when given to the second place they have an appearance of minute accuracy which is only misleading, for such accuracy is quite unattainable. I have only got a few observations of $\pi^1$ Orionis; but I give them, and such observations as I have of the stars $\pi^1$, $\pi^2$, &c., Orionis, below. I may here note, what is important in this connection, that the numeration of the stars lettered $\pi$ in Orion followed in Mr. Espin's letter, and below, is the numeration in Proctor's "Atlas."

| | | | | | | |
|---|---|---|---|---|---|---|
| 1883. | Dec. | 3 | $\pi^5$ | Orionis | 3·9 | Conditions pretty good. |
| ,, | ,, | 3 | $\pi^3$ | ,, | 3·9 | |
| ,, | ,, | 3 | $\pi^1$ | ,, | 3·8 | |
| ,, | ,, | 3 | $\pi^2$ | ,, | 4·3 | |
| ,, | ,, | 3 | $\pi^4$ | ,, | 4·5 | |
| 1884. | Nov. | 12 | $\pi^1$ | ,, | 3·5 | |
| 1885. | Jan. | 11 | | — | — | ($\pi^5$ = 4·0) |
| ,, | ,, | 11 | $\pi^6$ | ,, | 4·9 | Light orange. |
| ,, | ,, | 11 | $\pi^3$ | ,, | 4·1 | Light yellow. |
| ,, | ,, | 11 | $\pi^1$ | ,, | 3·8 | Light yellow. |
| ,, | ,, | 11 | $\pi^2$ | ,, | 4·7 | White. |
| ,, | ,, | 11 | $\pi^4$ | ,, | 4·8 | |
| ,, | ,, | 11 | 5 | ,, | — | Deep orange. |
| ,, | ,, | 12 | $\pi^1$ | ,, | 3·7 | Standard $\pi^5$ Orionis = 4·0. |
| | | | $\pi^3$ | ,, | 4·1 | |
| | | | $\pi^2$ | ,, | 4·7 | |
| | | | $\pi^4$ | ,, | 5·0 | |
| | | | $\pi^6$ | ,, | 5·0 | |

The observations of magnitude were made mainly with opera-glass; those of colour always with 45 on 3¼in.

60 *Leonis*. Mr. Espin has drawn attention to the fact that the colour of this star is now no more than yellowish-white. I had intended to draw attention to this fact. The following are my observations of this star.

1883, February 18 4 3 $\alpha$ = 1·6
1883, May 2 .... 4·1 $\alpha$ = 1·4

Of course, these observations are practically the same, the difference being due to difference in estimate of $\alpha$, which headed each sequence.

| | | | | |
|---|---|---|---|---|
| 1883, | May 26, | 4 4 | $\delta$ = 3 0 | |
| 1884, | March 17, | 4·2 | $\delta$ = 3 0 | |
| 1885, | April 8, | — | | Straw colour. |
| 1885, | May 7, | — | | Yellowish. |
| 1885, | May 9, | 4·3 | $\delta$ = 2·9 | |
| 1885, | June 4, | — | | Yellowish. |

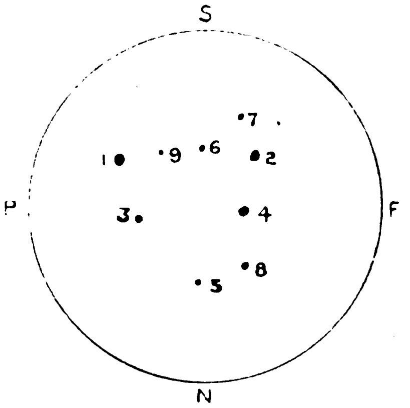
So far as these observations go, they show that 60 Leonis has not fluctuated in light, for the discrepancies are apparent only, being due to differences in rating of standards. I think the magnitude may be taken as 4·3. This is, practically, Argelander's magnitude. Heis, however, gives 5 – 4. I may add, moreover, that Mr. Gage, in the L. A. S. *Journal* for January (p. 61), calls it "light yellow."

B. 135. I observed this star on the 19th of February last, and noted it as "deep red orange."

B. 148. This is a very fine star, and is beautifully situated. I have the following observations of it:

1884. April 13: Fine orange.
1885. February 9: Fiery orange; a fine tint.

B. 437. Speaking of this star, Mr. Espin says: "The star D.M. 24·3395°, which Birmingham believes to be same as Secchi's star." I do not find this identification in the "Red Star Catalogue"; but as "Birmingham" in the "magnitude" column assigns a mag. from "D.M.," I presume it is the mag. of D.M. + 24 3395 he has there given? If so, it may be noted that it is 7·5, thus agreeing with Mr. Espin's 7½, I suppose.



Would Mr. Espin or Mr. Gore mind giving a little map whereby B 448 may be readily identified?

In "Ours" for June 27, 1884, I gave some observations and particulars concerning $\phi^2$ and $\upsilon^1$ Cancri. On the 7th of April last I observed them again. As regards $\phi^2$, I found the components to be practically equal, "if any difference, B the brighter." Concerning $\upsilon^1$ I noted, "At least one magnitude between the components. The colours differ." These observations practically agree with those I gave in my letter referred to above. They are both beautiful objects. In "Ours" for August 15, 1884, Mr. Stanley Williams gives some observations of his own, made with 5¼in. Calver, on January 3, 1881, when B of $\phi^2$ Cancri was found to be 0·1 brighter than A, and the components of $\upsilon^1$ were found to differ a magnitude; thus confirming my own observations, and showing that the relations in brightness existing among these stars was the same in 1881 as it is now. Both of these pairs are interesting, and worthy of further observation. From the observations given in "Celestial Objects," it appears that Struve found a difference of 0·5 in 1826; but that Webb found them "much less unequal 1849, nearly equal 1856." In the interval between 1849 and 1856, however, Dembowski had, in 1854, rated them as equal. Again, we find that while in 1871 and in 1874 Duner found "∓ 0·1 mag. difference"; in the year 1872 Webb found "¼ or ⅓ mag. difference" between the components, with his 9⅓in. reflector. There is, therefore, good ground for thinking the stars which comprise this pair to be variable in some way; but it may be noted, in addition, that in the observations given in "Celestial Objects," there is no word of B (the preceding star) being the brighter. The observations read as though A had always been found to have the superiority, whereas B certainly seems to be the brighter now.

In "Ours" for Aug. 1, 1884, I drew attention to the two small stars *p.* in field with $\gamma$ Leonis. I there said that I had found C to be about 9 6 and D about 10·3, and that on March 31 Mr. Franks had estimated them for me and made C 9·7 and D. 10·5. In the "E. M." for Aug. 15, Mr. Sadler gave a number of comparative estimates of the magnitudes of these stars, showing that they had been most variously estimated. C, he said, is 9·2 in D.M., and D is 9·5. Of D he remarked that "it was certainly not so low as 10·3 or 10·5 in 1882 and 1883, or in 1874—1877, according to my estimate." On May 11, when definition was pretty good, I examined these stars, using stops, and made C 9·7 and D 10·4 Arg. Perhaps some other observer can furnish notes on the magnitude of these stars.

In reference to Mr. Gore's very interesting note on B 607 (letter 24417, p. 388), I would like to know whether he has any other authority for the observation quoted from Burton, giving the magnitude in 1876 as 7·5, beyond the entry in the "Red-Star Catalogue"? I ask, for it seems to me to be possible that there is a misprint here in Birmingham. The "Red-Star Cat." says "Dublin Obs.: Copeland, 1875, Sept. 11, orange, 5·4. Burton, 1876, red, 7·5; Aug. 20, yellowish, 5; Oct. 10, yellow, 5·5." It will thus be seen that the change of magnitude, if the star was ever really observed in 1876 by Burton as being 7·5, must have been, at least, comparatively rapid; and that being so, it is strange that Birmingham does not draw attention to the circumstance. Neither in the text, on p. 297, nor in the list of stars to which, on the ground of their being perhaps variable, he "would specially direct the attention of observers," which occurs on p. 300, does he mention No. 607. It is noteworthy, too, that although he points out on p. 300 that variability was "observed . . . by Mr. Burton in 502," he does not say that he observed it in 607, though we might have expected that had Burton actually observed the variation mentioned under 607, he would have drawn attention to it. Variability might certainly be, I think, inferred from the statement quoted by Mr. Gore from Sir W. Herschel, and might be, perhaps even ought to be, also inferred from the observations of Secchi, given in Appendix I. to the "Red Star Catalogue." These observations of Secchi's strongly suggest variability in the spectrum as well. B 607 is a beautiful star in colour. The following are the only two observations of it of my own I can find:—

1884, Sept. 21 ...... Ruddy gold.
„ Nov. 27 ...... Orange; in moonlight.

I would like to direct attention to Alcor, for it seems to me to be unusually bright at present. I had observed it on previous occasions to be about 4·6 or so; but I thought the other night that it could not be much less than 4·0, and last night (8th July) I compared it—but roughly though, I must say—with λ Boötis, which star I have found constant at 4·0, and made it 4·3. That Alcor must be at present a good deal brighter than it was once, must be, I think, taken as certain; but I have a fancy that its present brightness is not constant, but subject to fluctuations.

Allow me to thank Messrs. Sadler and Tarrant for the large amount of information they supply in answer to my queries in letter 24390 (p. 364), in to-day's "E.M." Mr. Sadler will see from par. 1 above that I *did* write "B.," and not "β." I must say, however, that I have often thought that "β" is an inconvenient symbol to adopt for "Burnham," and that it would be much better to always employ the contraction "Bu" used by the late Mr. Webb throughout the whole of "Celestial Objects."

Glasgow. **S. Maitland Baird Gemmill.**

## ASTRONOMICAL.

[24481.]—I think we may accept it as a fact that an elongation of γ Coronæ exists towards 135° or 140°, since independent measures by M. Gaudibert, Mr. Tarrant, and myself all give the same angle, but the elongation is very slight, and I am told the present distance is less than 0·3″.

I think "M. G." (24439) will find his measure of η Coronæ 5° too large. 70 Ophiuchi I have measured twice as 28°.

Mr. Kershaw (24458) asks about paraffin covered vessels for silvering. My silvering vessel is made from a piece of plate glass with a glass ring cut from a glass shade upon it. This ring is about 2in. deep and is united to the slab of plate by brushing hot paraffin wax round. I have noticed that less silver deposits upon the wax than upon the glass, and have not noticed it affect the film in any way. An ordinary wax candle melted down seems to do just as well as pure paraffin.

Mr. Franks, letter 24459, in remarking that while a 4in. o.g. with a power of 200 gives a brilliant image of Jupiter, "I have never seen a 2in. yet that I should care to observe the planet with when charged with a power of 100," forgets that a 2in. does not collect enough light to make the features of Jupiter observable at all. He is also accustomed to a much larger aperture, and therefore dissatisfied with small instruments. But evidently the first necessity of the case in any comparison is that the instrument shall not be too small to show anything. It is not the comparative quantity of light, but the total quantity that is in question here. A 4in. may, with a power of 200, show a lunar crater distinctly, while a 2in. with 100 fails to show any crater at all. Does this prove that the 200 on 4in. is borne better than 100 on 2in.? I think not. It only proves that the total amount of light collected by 2in. is insufficient to affect the retina. If we look at a bright star with a faint companion, the disc of the larger star will be as sharp and well defined with 200 on a 2in. as with 400 on a 4in.; but the faint *comes* visible in the one is invisible in the other, not from want of proportionate, but for want of absolute, power. Again, when Mr. Franks asks if a 26in. would bear 1,300 diameters on Jupiter, and opines it would result in a "fearful and wonderful illustration of what the atmosphere can do in setting optical theories at defiance," does he not see he is discussing an entirely different question? That our atmosphere might render such a power useless may be quite true without affecting the truth of optical theories in any manner. His first proposition relates to the comparative light; but this is a question of the comparative effect of atmospheric disturbances on various apertures.

I think he will see there is an inherent defect in his quotation from his private correspondent. He, in effect, says that the brightness of the object will be the same in a 2in. with a power of 100 and a 4in. with 200. If this were correct, it would go to prove that a faint *comes* would be just as easily seen in one telescope as another, provided proportional powers were used. I am sure I need not waste space in refuting this, although Mr. Franks has inconsiderately indorsed it.

It is the total quantity of light collected that enters into this question. Again, and as in the larger instrument, the actual image of any point is identical in size with corresponding powers (that is the image of a point in a 4in. with 200 is exactly the size of image in a 2in. with 100), then, as the 4in. collects four times the quantity of light, and delivers it in the same space, the image in the 4in. is four times brighter than in the 2in. This is just as true of any larger aperture.

With regard to the question he puts further, I should regard the failure of a 26in. to stand 1300 on a steady night as a proof it was defective. I have found a 9in. stand 900 easily enough on stars, and 600 on planets. **E. Holmes.**

## HIGH-POWER GLASSES.

[24482.]—Replying to "E. C. J." (24461), the difficulties raised by the A. and N. Stores are now surmounted as regards non-members. I had to go myself for a 7-power glass for another "E. M." reader since Dr. Dickson's, and when there I saw another 7-power which yet another reader had succeeded in ordering to his special width of 65mm. in aluminium, but which the authorities had since refused to deliver to him. To stop this I wrote, acting on the Editor's late suggestion, to Mr. William Whiteley, of Westbourne Grove, who has consequently to-day agreed to order samples of 4, 7, and 10-power glasses from the maker in Paris, and to execute orders for the same to all applicants, at the same prices as those already quoted by the A. and N. Stores. Answering "E. C. J.," why 10-power should be so much more costly than 7, ten diameters cannot be achieved under a focal length of 10¾in.; this will not allow less than 8¼in. as length closed, unless double draws are resorted to, which is bad in principle. Hence the amount of material needed. Then the object-glasses are 2⅜in. aperture. It is a really valuable instrument. The glasses in their cells weigh 9oz. out of the total weight 20oz. Substituting brass for aluminium would greatly decrease the price, but increase the weight. For some years these glasses cost £12, and it was only on my holding out prospects of the present demand that the maker went afresh into the figures, and reduced the tarif to the present price, 181s. "E. C. J." also asks if it is not the fact that all glasses are made in France? I believe he is right in his assumption. It is not disputed that all the aluminium work is done in France exclusively, and the efforts to assert that *soi-disant* English glasses are made in England are feeble, and I doubt if they would stand cross-examination. I regret it is so. I would much prefer to see both the lens trade and the aluminium trade established and prospering in England for England's sake. Till then the best thing for England is to supply her with the best French-made glasses, on the best terms attainable to leave the Paris maker his fair profit and the London agent his fair commission. In this matter I have not interfered: the prices quoted include everything they asked for.

I hardly know whether "Experience" expects replies to his questions (24462), for they are so self-evident. He reads of my taking the bin. telescope and 10-power Galilean to Albert Hall to try their respective capabilities, and that at 5 p.m. by daylight the former could hardly distinguish features across the hall, while after night came on, and the evening performance was conducted before 6,000 spectators by gaslight, "the telescope could show nothing, while the 10-power showed everything equally well as by day." To this he asks, "What can 'Montmartre' mean?"

Then he proposes to ask "whether increase of power can be obtained without any sacrifice of light *or field?*"—a question which is itself a contradiction in terms as regards field. (Mr. E. M. Nelson, in our current issue, 24460, brings the weight of his opinion to the effect that there is no loss of light in a 10-power on a 2in. aperture.) The one contention of the supporters of the high-power glasses is, that it is common sense and sound practical wisdom to exchange the useless excess of field, with low power—which has so long been pressed upon the market—for the more effective and useful high-power, combined with the correspondingly smaller field, which are the raisons d'être of the 4, 7, and 10-power glasses having been designed and advocated.

I have no doubt that for years past the glass-using portion of the community have been carrying about with them a needless excess in size, weight, and cost in glasses, which is now destined to be revolutionised by the introduction of the present choice of instruments, each of which represents the maximum of effectiveness attainable for its sake, at, apparently, from a half to a third of the cost of the old stocks. **Montmartre.**

---

[24483.]—Replying to our two correspondents, Dr. G. Dickson, of Edinboro' (24436), and G. R. Baker (24437), I despatched the former a 7-power at 39s., in brass (the "superior article" at 56s. was a fiction—there is nothing better made), and I can assure the latter that the fears he expresses about the high-power glasses are unfounded. I used myself to have what he terms "a battery" of twelve or fourteen glasses of all makes, but the last ten years' experience taught me that the high powers are worth all the rest put together, and I have given away all the low powers except one, which I keep for sweeping the skies. The 4-power for the ticket pocket companion, the 7 for ordinary theatres and concert rooms, and the 10 for outdoor work, the Albert Hall, and Hippodrome form, I find as complete a range as can be desired for all purposes. Although I have no acquaintance with those occupations myself, I also know that the 10-power has been purchased for use with satisfaction in yachting, duck shooting, and racing. Neither do the fears Mr. G. R. Baker expresses conform with the verdict of the actual purchasers—"Which I have received, and with which I am delighted"—"What I have been wanting for years past"—"I am of your way of thinking—power first, light next, field last"—"The writers who say people do not want to see too much talk bosh; people want to see all they can." These are the types of the remarks of the possessors of the high-power glasses. One of our readers—not Baker—who also went to Paris a few days ago, selecting his 7-power personally at the makers, actually defrayed his first-class fares and bill at the Grand Hotel out of the difference saved between the cost of the 7-power so acquired (though he paid London agency price for it) and that of the 6-power offered by the English advertisers in London! His verdict was "Greatly pleased, the most powerful yet made, for I know those offered by the London firms well."

Dr. Dickson writes to-day from Edinboro': "The 7-power sent has excellent definition, reasonable light, and good achromatism. As to aperture, it should not be complained of when put beside the great advantage of high power. I tried it against a large aperture glass, and could read print distinctly at double the distance with it. I also tried it from Arthur's seat last evening, and, although hazy, could make out the French flag of a vessel five miles away. Accept best thanks for putting in my way what I have sought for for years." Such expressions as these make me feel—thanks to the "E. M."—as comfortable as the party who "made two blades of grass to grow where but one grew before." **Montmartre.**

## PIANOS AND THEIR SHAPE.

[24484.]—So much has been said about the mechanism of the pianoforte in these pages, and so much benefit has resulted, that I crave a word or two on the subject of the form of the instrument. The ordinary upright piano, as made at present, is the most hideous thing in a room, and if we try to get anything of decent design we have to pay prices far beyond the means of common people. Is there any reason why pianos should still be so ugly? Why cannot Mr. Davies, for instance, who makes such good cheap pianos, make us one like the piano I saw recently on view in "Old London" at the Inventions in the room furnished by the "Century" Guild? I wish we had a little more about art occasionally in "Ours." We have become emancipated from the thraldrom of the upholsterer to the benefit of our pockets and the gratification of our sense of the beautiful; but the pianoforte is still a terrible nuisance in a room furnished with any pretensions to taste. **Kappa.**

### EXAMINATION OF MINERALS BEFORE THE BLOWPIPE.—II.

[24485.]—Box No. 6.—Yellowish white, amorphous fragments; compact, but glittering—hard.

| | | |
|---|---|---|
| I. | Powder in B acid. (1.) Transparent ice-like mass, not wholly dissolved. (2.) Green pyrochrome nearly yellowed. | (1.) An alkaline aluminous silicate, with large proportion of silica. (2.) about 5 per cent. of soda. |
| II. | Added CoO. (1.) Cobalt borate nearly all dissolved to purple suffusion over the bead. | (1.) About 10 per cent. alkali (must be potash also here). |
| III. | Added lime. (1.) Calcium borate balls decomposed in part, but milky matter not quite opaque. | (1·) Not very much alumina. |
| IV. | Fragment fused easily before the pyrocone: Powdered, boiled, dried, and treated B.B. in phosphoboric acid. (1.) Semi-transparent undissolved mass. No balls of any kind. | (1.) Large proportion of silica. No lime, iron, manganese, &c. No necessity to try this mineral in P acid. |

What Mineral is this?

Box No. 7.—Compact, white, amorphous fragments, with vitreous lustre; very hard (steel of penknife left on its surface).

| | | |
|---|---|---|
| I. | Powder in B acid. (1.) Strong yellow p.c. from bottom of bead, and green p.c. completely yellowed. (2.) Ice-like mass dissolving. | (1.) Large proportion of soda. (2.) An alkaline aluminous silicate. |
| II. | Added CoO. (1.) Great part of cobalt borate dissolved to purple suffusion. | (1.) At least 10 per cent. soda. |
| III. | Added lime. (1.) Lime balls decomposed; at first with curdy precipitate round them, then completely, to milk-white enamel bead. | (1.) Considerable proportion of alumina. |
| IV. | Original powder in P acid. (1.) Transparent mass after long treatment before pyrocone. | (1.) Large proportion of silica. |

(Did not try for lime, &c., as the mineral is evidently a relative of the preceding.)

Box No. 8. (On opening this box I could see from the iridescent play of colours on some surfaces of the fragments, that the mineral is labradorite, and as I have found this out, and have already given a blowpipe analysis of that in "E. M."—see "Easy Lessons, &c."—I pass it by, and take instead, a small piece of a mineral inclosed in paper in the box, of which someone had sent me one or two small fragments) flesh-coloured, compact, amorphous, soft.

| | | |
|---|---|---|
| I. | Powder in B acid. (1.) Ice-like mass not soluble. (2.) Yellow p.c. at first, but green p.c. not completely yellowed. | (1.) Alkaline aluminous silicate with little alkali and much silica. (2.) Under 5 per cent. soda. |
| II. | Added Co O. (1.) Cobalt borate balls scarcely purpled. | (1.) Little alkali. |
| III. | Added lime. (1.) Only curdy precipitate round lime-balls. Added equal parts of CaO and original powder. (2.) Only milky and opaque in part; but this bead had a trace of P. acid, derived from the wire in it. | (1.) Not much alumina.<br>(2.) Not much alumina; but allowing for the state of the bead, I should say about 15 or 16 per cent. |
| IV. | Fused, boiled, and dried powder in fresh B. acid. (1.) Semitransparent fragments, some giving off faint milky streaks; no balls. | (1.) (1.) No lime, iron, &c; but I had *very* little of this mineral, wishing to retain parts, and was obliged to fuse remains of original powder made into paste, instead of a fragment B.B. |
| V. | Added P. acid and fresh, boiled, &c., powder. (1.) Same as before; no balls. | |

(Unsatisfactory; but think I can guess the mineral from these reactions, and its peculiar flesh colour.)

Box No. 9.—White, opaque, crystalline-fibrous: soft.

| | | |
|---|---|---|
| I. | Powder in B. acid. (1.) Transparent, icelike mass, dissolving to clear bead. (2.) Green p.c. completely yellowed. | (1.) Alkaline aluminous silicate with considerable alkali. (2.) Over 5 per cent. of soda. |
| II. | Added CoO. (1.) Cobalt borate completely but not rapidly dissolved to purple suffusion; not to a blue bead. | (1.) Over 10 per cent. alkali, but under 20 per cent. |
| IV. | Added a mixture of equal parts of lime and original powder. (1.) Milk-white, opaque, enamel bead. | (1.) Considerable proportion of alumina. |
| IV. | Powder of fused fragment (fused easily with strong reddish orange p.c.) boiled and dried in phosphoboric acid; (1.) semitransparent mass with one or two minute colourless balls. | (1.) Considerable proportion of silica, with a trace (one or two per cent.) of lime; no iron, manganese, &c. |

What Mineral is this?

Box, No. 10.—Greenish grey, compact, amorphous; softish.

| | | |
|---|---|---|
| I. | Powder in B. acid. (1) Faint yellow p.c. at bottom of bead, but green p.c. unaltered after. (2) Rusty yellow suffusion over whole bead, with black enamel over wire. (3.) With much fresh B. acid and a trace more powder, many black opaque balls, surrounded by yellow suffusion. (4.) Vesiculated, no ice-like mass or fragments, but one or two larger transparent brown balls, iron borate balls rapidly dissolving. | (1) (2.) Trace of soda, but presence of considerable alkali, by which iron borate balls are dissolved to black enamel, &c. (3.) Large proportion of iron. (4.) Either a large proportion of potash or less of some stronger alkali, not soda, a little manganese. |
| II. | Added CoO. (1.) Cobalt borate balls, with little suffusion, and that pink, not purple. | (1.) Cannot be potash, yet must be considerable alkali present to dissolve the iron borate. |
| III. | Added lime. (1.) Lime balls not decomposed, but take up the CoO as transparent purple balls of cobalt-calcium borate. Almost impossible to vesiculate the bead. | (1.) Either no alumina present or the alkali must be Lithia, probably both. |
| IV. | Splintery fragment before the pyrocone point. (1.) Yellow p.c. but streaks of deep red; more red if the wick of a pyrological candle (!) is touched with the fragment. | (1.) A little soda and more lithia, but still not much of the latter. |
| V. | Boiled powder of the fused fragments, dried, and treated in fresh B acid bead. (1.) The whole powder, black opaque balls with streaks of cohering opaline matter; forming afterwards a peculiar opal bead B.B. | (1.) The whole mineral iron, with (probably) largo proportion of phosphoric acid; a little lithia, and traces of soda and manganese. |
| VI. | Equal parts of boiled powder and lime added to V. (1) A large, black, opaque, conglomerated ball, like that afforded by Gayolinite to B acid. | (1.) Not much information from this reaction, except the probable presence of magnesia. |
| VII. | Added powder of V. to fresh B acid bead containing a large calcium borate ball. (1) Transparent green ball, opaque while hot. | (1.) Iron protoxide with a little magnesia. |
| VIII. | Added potassium pyrotungstate (!) (*a*) in excess to bead I., B.B. (1.) A deep turquoise-blue, opaque bead on cooling. | (1.) Large proportion of phosphoric acid. |

It is pretty plain now what this mineral is.

*Notes.*—*a.* This salt (an invaluable reagent for phosphoric acid) is thus made:—Fuse a portion of potassium carbonate, about the size of a large pea, on clean aluminium plate B B, and add tungstic acid (!) (a yellow powder sold cheaply in small bottles), until all effervescence has ceased. The product, a greyish white mass, is broken into little pieces and kept for use in a small bottle; but I prefer making it "fresh and fresh," as above described. To use it, the supposed phosphate is first thoroughly dissolved in a B acid bead B. B. by the employment of as little potash as possible (a mere trace is sufficient), so as retain a decidedly acid character in the bead. Potassium pyrotungstate is then fused with this bead inside the point of the blue pyrocone; and if it is phosphatic in the least degree, it will turn a pale turquoise blue, and opaque on cooling: if very phosphatic, it will turn a deep blue.

I discovered this test (it is said by some "Ironmasters" to be invaluable in detecting traces of phosphorus in iron, which is then said to be "cold short") in 1874, by a careful perusal of Plattner's celebrated "blowpipe tables" (Probirkunst mit dem Löthrohre," 4th Ed. 1865, p. 138). In them I saw, under the head of "No. 33, Wolframsäure" (tungstic acid), that that substance, added B. B. to borax, affords only a yellow bead; but when added to salt of phosphorus, a "beautiful blue colour." Soda being common to both of these salts, it is evidently phosphoric acid which causes the blue colour.

P.S.—I feel much indebted to "Ex-Blacksmith" and a "Mineralogist" for their kindness in noticing my work in the "E. M."; but I cannot look in the list of minerals yet to see if they are right or wrong, because I should then be unable to help seeing the names of the rest; but I shall be able to ascertain the names after this lot, when I have some remarks to make upon their remarks. **W. A. Ross.**

### FLAMES.

[24486.]—THE old theory as to the cause of luminosity in flames was that solid particles of carbon are deposited, and being heated to whiteness in burning hydrogen, emit light. In support of this theory was adduced the fact that gases, such as hydrogen, whose flames are incapable of depositing solid particles, have but little luminosity when burnt; and it was also argued that the soot formed on a cold surface held in a hydrocarbon flame is the solid carbon to the incandescence of which the luminosity is due. Hydrogen burning in oxygen yields water vapour whose density is only 9, and the flame, though very hot, is of feeble luminosity; if the hydrogen be burnt in chlorine the density of the product of combustion is 18·25, and the flame, though probably lower in temperature, is much brighter. One of the most brilliant flames in existence, that of phosphorus burning in oxygen gas, certainly does not contain solid particles of any kind, for phosphoric anhydride is volatile at a temperature far below that of the flame; and the same remarks apply to the flame of arsenic burning in oxygen, which is very luminous, although solid particles are out of the question. We thus see that we can have luminous flames without solid particles, provided that the vapour density of the product of combustion is high; in the case of arsenic the vapour density is 198, and in the case of phosphorus (probably) 142. We have now to inquire how this theory will fit with the phenomena presented by ordinary gas flames. Coal-gas is of low density, generally about eight or ten, and the flame is much more luminous than would correspond to this density or to the density of the products of combustion. We know, however, that the ignition of gaseous hydrocarbons has the effect of causing the formation of compounds of higher molecular weight. If marsh gas be heated, part of it is converted into acetylene; and, indeed, it is possible, by simply igniting, to pass from the lower members of the paraffins to the more complex molecules of the aromatic hydrocarbons. In an ordinary gas flame, therefore, there are found hydrocarbons of great complexity, whose vapours, intensely heated, emit light.

Soot, which was considered to be merely carbon, in reality always contains hydrogen, which cannot be removed by mere ignition, but only can be got rid of by heating to whiteness in a stream of chlorine. Soot is, in fact, a hydrocarbon of very high molecular weight, which is formed in the flame by the ignition of coal-gas, and which, as vapour in the flame, emits light. It may be asked Why, then, does it not volatilise again on ignition? But these very heavy hydrocarbons will not volatilise twice. The tar in the hydraulic main of a gasworks has been distilled there, but it cannot again be completely sublimed. As a minor argument against the existence of solid particles in a gas flame may be cited the transparency of the flame. A newspaper can easily be read through a flat flame, which would scarcely be possible were many solid particles present, but is quite compatible with the existence of incandescent vapour. Other things being equal, the hotter a flame the greater is its luminosity; but mere temperature in the absence of heavy vapours is useless. It is, however, probable that each density has a certain temperature at which it becomes luminous. The solar prominences consist mainly of hydrogen, and are very luminous; but then their temperature is enormous, and far exceeds any flame we can obtain. If air be admitted to the gas flame, as in the Bunsen-burner, then the combustion is so rapid that the formation of heavy hydro carbons cannot occur, and the luminosity vanishes, being then only that due to the products of combustion—namely, steam and carbon dioxide. The temperature rises considerably, but not enough to render incandescent the light gases produced.

* One, the 5 p.m. from King's Cross on Sundays. † One, the 8.20 p.m. from Peterborough on Sundays. ‡ One on Mondays and Wednesdays only. One on Thursdays only.

From this list it will be seen that the G.N.R. is by far the fastest line in the kingdom. It has also the longest run without stoppage. I hope we shall hear no more about the Dutchman being the fastest train.

**D. A. P.**

### GRAVITY BRAKE.

[24488.]—I SEND a short description of gravity brake (letter 24468). I do not know, however, whether it is in use on any railway at present. The construction and action of this brake are simple, and the parts few. There is centrally attached to the underbody of each carriage a vertical cylinder, in which a piston and ram, weighing about 150lb. or so, as required, is free to move; the cross head of ram, connected with and acting through levers, actuates the brake blocks. The ram, when in its normal position, is at the bottom of the cylinder, but not quite touching. Thus, when left to natural forces, the brake blocks are forced against the wheels, and remain on until released. This constitutes the great difference between this and other brakes, there being in the gravity brake no power to leak off, as is the case with air and vacuum system; consequently, the driver must take the whole of the brakes off before he can start a train: this insures it is in good working order.

There is provision made in three different ways if required for releasing the brakes, two for working the brake in actual running, one for releasing brake when required for shunting purposes. This latter is done by means of a manual lever on each carriage. If, however, this lever is accidentally left fastened, and the brake off, the driver can release it from the engine, and thus work the brake as usual.

For taking off and working the brake whilst running, there is the usual length of pipe from end to end of carriage, &c., as is common to all systems of continuous brakes. Primarily this may be used in the ordinary way to maintain a vacuum by means of an ejector on the engine. While the vacuum is maintained the brakes are fully off; when diminished they are partially applied; when destroyed they are applied with full force. A vacuum of 8in. is sufficient to keep the brakes off. A special driver's valve fixed on the engine, enables them to be worked with the greatest nicety. It must be noticed that the vacuum pipe is connected with the upper part of the brake cylinder.

Similarly, compressed air can be used; this pipe must however be connected with lower part of cylinder. As this brake can be worked either by vacuum or air pressure, every individual carriage may be made up in the middle or any part of trains on other lines which may be fitted with either systems as now in use, and the brake will work equally well, which is an immense advantage. This brake is essentially automatic under all conditions. There is also an arrangement on each carriage, automatic in action, for maintaining the levers at their most efficient angle, and perpetually taking up the wear of the brake blocks.

The patentees are Messrs. Cowling Welch and Parker Smith.

July 11. **Nomen.**

### NEW TRAINS, &c.

[24489.]—MR. LAWRENCE (letter 24468) is very wide of the mark when he says: "I think at present the L. and N.W. are running the fastest." The distance from Willesden to Rugby is $77\frac{1}{4}$ miles, not 78 miles, and consequently the speed of the run referred to is below 53 miles per hour.

The following are the only runs in England at a speed of 53 miles and over. It will be seen that the G.N. run 355 train-miles daily at this speed, and the G.W. $231\frac{3}{4}$.

| Company. | From | To | Miles. | Time. | Speed. |
|---|---|---|---|---|---|
| 1. G.N. | Grantham .. | King's Cross | $105\frac{1}{2}$ | 1.58 | 53.64 |
| 2. G.N. | Huntingdon | Finsbury Pk. | $56\frac{1}{4}$ | 1.3 | 53.57 |
| 3. G.W. | Paddington. | Swindon.... | $77\frac{1}{4}$ | 1.27 | 53.28 |
| 4. G.N. | Grantham .. | Peterboro' .. | $29\frac{1}{4}$ | 0.33 | 53.18 |

No. 1 is performed twice daily, 1.47 p.m. and 4.17 p.m.; No. 2, once—viz., at 4.34 p.m.; No. 3 is done three times (twice down and once up); and No. 4, three times, all up.

The number of train miles at 52 miles per hour and upwards are:—G.N., $686\frac{3}{4}$ miles; G.W., 309 miles; L. and N.W., $77\frac{1}{4}$ miles (the run referred to by Mr. Lawrence). None of the other companies reach 52 per hour. The best on the M.R. is about $51\frac{3}{4}$.

Concerning No. 2 run above, it should be noticed that the times given in the tables at Finsbury Park are the departure times, and that two minutes are allowed there.

The N.E.R. time bills agree with Bradshaw concerning the run from Newcastle to Edinburgh. The distance is $124\frac{1}{4}$ miles; and judging from the time allowed, I should fancy that a stop is made on the way, though possibly not for the benefit of the public.

If Mr. Lawrence would make a few journeys between King's-cross and Grantham, he would soon find an explanation for the hitting of the arrival time to such a nicety. The driver simply gets two or three miles in hand, and then runs the last few miles easy.

Undoubtedly, until recently, certain engines on the L. and N.W. did run to Crewe and back on the same day, though whether this is still the case I cannot say. **C. P.**

### THE ACCIDENT AT KING'S CROSS.

[24490.]—WILL Mr. Stretton give such particulars as are available of the accident which occurred at King's-cross the other day, when two trains tried to run up to the King's Cross (underground) up platform at the same time? I understand that a Great Northern goods ran into a Midland passenger, both engines (fortunately) meeting where the lines converge. It is said that the signals were "off" for both trains, but all that is certain is that somebody blundered. If the signals were "off" for both lines, I would ask, Is there any difficulty in so arranging the levers that it would be impossible for the most careless signalman to put one signal "off" unless the other was "on." The accident, fortunately, was unattended with any serious injury to passengers, the two engines obligingly coming together as before (p. 386, No. 1032); but whose fault was it? **Nun. Dor.**

### COLLIERY EXPLOSIONS.

[24491.]—COL. J. D. SHAKESPEARE, in letter 24447, has brought this subject forward with a remedy which must convince the owners of collieries that it ought to be adopted. About 12 years ago I had the twin idea: 1, to force the gas back, or, at least, to prevent it from escaping into the mines; and, 2, to suck a fire out of a room or house, or to, at least, prevent it from spreading. The first idea, which Col. Shakespeare has so ably brought forward, I did not dare to publish, because my knowledge of mines is so small that I could not see whether it were possible to carry it into practice. The second idea, to suck out a fire, was submitted by me to the Society of Arts about ten years ago, on the occasion of that society offering a prize for the best means of extinguishing fires. The idea of preventing the gas escaping into the mines was brought out in "Ours" about eight years ago, I think; but I have forgotten the name of the writer of that letter. No further correspondence ensued at the time. I hope this time, however, those of our correspondents who have sufficient knowledge of mines will come forward and give their help to try to remedy this fearful sacrifice of life. **J. H. Schucht.**

## GRINDING TOOLS FOR HAYDON'S CUTTER-BAR.

[24492.]—As I have paid some attention to this during the last few years, I shall be glad to be allowed to explain the system I have adopted. Fig. 1 is merely a sketch of a 2ft. grindstone with a hoist; Fig. 2 shows how the hoist is made. This I find much better than blocks, which have previously been recommended in the "E.M." Fig. 3 will require more explanation. It is a grinding gauge, and some care is advisable in setting it out. Get a large sheet of paper, on which make a semicircle the exact size of half your grindstone; draw a line through the centre, mark this with 0 for zero, then set out 3°, 5°, 7½°, 12°, 17°, 21° and 25½° above zero, and 9°, 10°, 10½° and 12° below it, draw in lines as dotted in Fig. 3. The parallel lines will give the height at which the tool should be ground if it is held in one of Mr. Haydon's cutter-bars properly made. A, Fig. 3, shows the gauge I use. It is made of brass. The drawing will explain itself; but when in use the end B must rest on some part of the grindstone frame so as to bring the line marked "120 steel" exactly up to the centre of the stone. Suppose an ordinary tool for wrought iron is wanted, place the gauge in position as shown in Fig. 1; put the cutter bar on the board on the top of the hoist, raise it up until the point of the tool reaches some part of X, the top of which gives 5° and the bottom 3° for relief; remove the gauge and advance the tool, but at an angle, grind one of its lower sides, bring the end of the holder round 60°, and grind another of the lower sides. You should then have a plan angle of 120°. Reverse the tool in its holder, raise the hoist until the point of the tool comes up to the gauge mark "120 iron," grind (what will be the top face of the tool) at this height; we shall then have a first-class tool for iron with cutting edges of 60—if the same tool had been ground at "120 steel" the cutting edge would have been 70, if at "120 brass," it would have been 80. This holds good with any other plan angle if ground at at its proper mark on the gauge, that is, say, plan angle of 90°, must be ground at the 90 marks.

FIG. 2

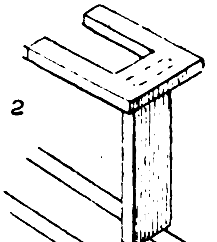

FIG. 1

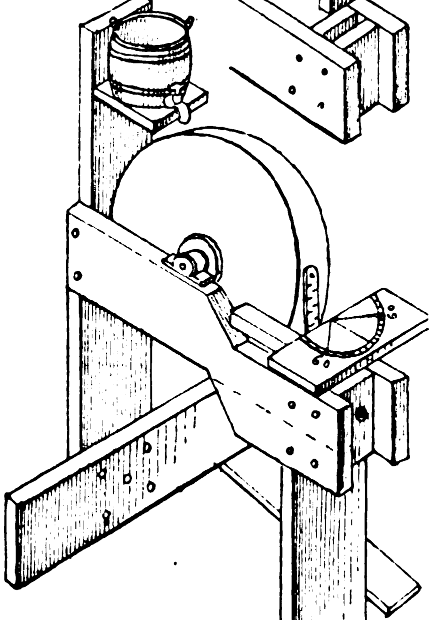

FIG. 3

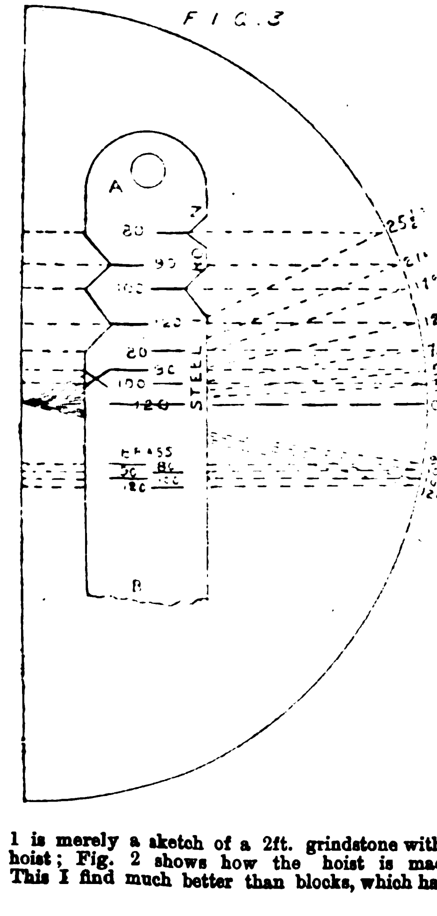
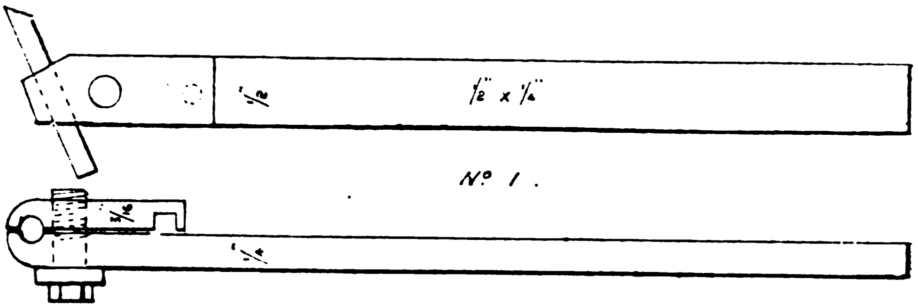
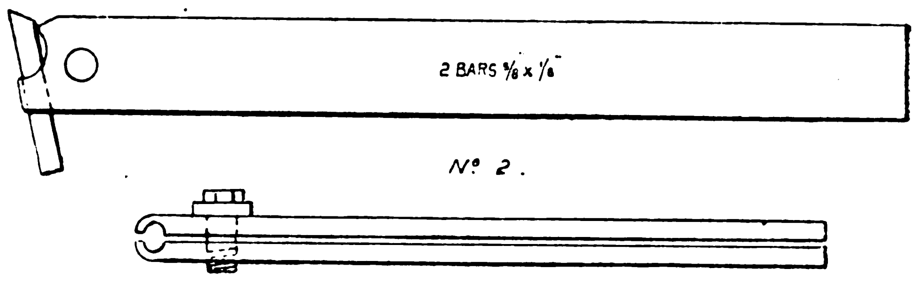


Now that "O. J. L." is giving us some articles on Mr. Haydon's double-edge system, let me advise all amateur turners in metal to closely follow his instructions, and make up their minds to thoroughly master it. For myself I can say I never go to the lathe without feeling a pleasing sensation of gratitude to Mr. Haydon, and it was with great sorrow I heard of his serious illness. For years I had been attempting slide-rest practice in metal with a small bench lathe on triangular bar. It has no back gear, and the slowest speed is two of mandrel to one of crank. My tools would grind rather than cut off a little metal. At last my attention was called to Mr. Haydon's double-edged tools and cutter-bar, and I got a set. They would not cut, and so I packed them off direct to Mr. Haydon, only asking if the fault was mine or the tools. But he went further than this, sent me several long letters, made me master of the principles of the double-edge tools, and told me how to grind. About a year after this he gave me several sheets of drawings that he had got out to illustrate the whole principle. These were intended for a book he had in hand, but unfortunately I fear unfinished. The result of his instruction is, with the same lathe I have this week removed half the metal from a ¾in. bar of iron by one trip of the tool. I never have a tool that will not cut, for they must cut. An old hand, seeing some shavings on my bench, said, "What, are you turning—lead?" This I consider the greatest compliment he could have paid to the system, except that he has since adopted it.

I wish all amateurs would give it a trial. Just a simple tool for general work at first, and it would eventually take the place of all tools for the slide-rest. **A. Atkinson.**



No. 1.



No. 2.

## SIMPLE CUTTER-BARS FOR 5in. LATHE.

[24493.]—I inclose drawings of two cutters which I have adopted after many trials. They are up to the work of a 5in. amateur's foot-lathe, and their simplicity of construction brings them within the means and tools of almost all amateurs.

No. 1 has a bar of ½in. by ¼in. steel, with a side clamp of 3/16in. by ½, gripping the cutter by a ¼in. screw.

No. 2 has a bar of two pieces, end ⅛in. by ⅝in. in size. Both held a round, square, or triangular steel Stubb's wire cutter in grooves, which are roughened or toothed by running a tap through them. The steel cutter it is well to roughen also; this may be done by indenting its sides with a cold chisel before tempering or hardening. It is not necessary to harden or temper the cutter-*bar* itself. These bars are as large as will conveniently go into the tool part of an American 5in. foot-lathe. **M.**

## DEAD-CENTRE LATHES.

[24494.]—You have, in last Friday's number, an engraving of Mr. Hampson's dead centre for lathes. Mr. Hampson's invention is 20 years old, for in 1865 my respected foreman, David Kemp, had five lathes made, four for our own use, and one for France, according to his instructions, of better construction than Mr. Hampson's, to turn two shafts in one lathe, either with dead or live centres, and the same can be seen working any day at Victoria Engineering Co., Limited, Stockport, where for this last 20 years I have worked.

**Samuel Jackson (Machine Hand).**

## AUTOMATIC MUSICAL INSTRUMENTS.

[24495.]—It is surprising that "A. S. L." (p. 412) should persist in his contradictions, when he could so easily settle the matter by examining an organette at one of the music shops, and, by referring to his back volumes, obtain other evidence. I gave chapter and verse for my statements on p. 587, Vol. XXXIX., and on p. 540, same vol., I wrote "as soon as the original inventor in America discovered that he could do better without levers, Mr. M. J. Matthews also found that his patent was worthless, and commenced the manufacture of orguinettes without levers." Orguinettes and organettes are practically identical; they are as like as two peas in their constitution. With reference to "A. S. L.'s" statement, I find on inquiry that a gentleman having those initials did receive a rough sketch of the lever action organette, but that was taken from, I believe, the only instrument of the kind that reached this country. Certainly not more than three ever came over, for the inventor soon found that levers were not only troublesome, but costly. Of course, as the orguinette was a colourable imitation of the organette, that too had levers at first, and was illustrated in No. 733. Your correspondent apparently forgets that the English Mechanic goes into all sorts of places in the habitable globe, and that it is just possible it may get into the hands of people who know more about this matter than he thinks for. At any rate, I did not write in Vol. XXXIX., nor recently, with the purpose of contradicting "A. S. L.," for I have too much to do to waste ink on that object; but I wrote because, being a humble member of the great army of English Mechanics, I wished to correct mis-statements and put the truth before my fellow-readers. The sketch, then, on which

Comparison of Tides at Liverpool and Fleetwood, for the month of June, 1885.

| Date. | Calculation. | | Observation. | | Error. | Barometer | Wind. | Remarks. |
|---|---|---|---|---|---|---|---|---|
| | ft. | in. | ft. | in. | in. | | | |

| | 24 | 8 | 24 | 0 | − 8 | 30·0 | N.N.E. | — |

"A. S. L." has relied, referred to the original organette, as first made; but it was certainly not made on a commercial scale with levers. The discovery that perforated paper did "as well" (I am not going to argue that point again), soon settled the levers, and as the orguinette was simply a copy of the organette, of course its levers were abolished too. If "A. S. L." had access to the patent cases tried before the U. S. Commissioners (McTammany *v.* Matthews, and Others) he would have indisputable evidence of the truth of the statements made.

**Gray's Inn.**

## COMPARISONS OF TIDES AT LIVERPOOL AND FLEETWOOD.

[24496.]—The results obtained for the month of June at Fleetwood have been tested with those obtained at the self-registering tide-gauge on Helbre Island, the datum-line of which differs usually by a foot from that placed on George's Pier, the reason being that the tides usually rise a foot higher at the latter station than at the former in consequence of the situation being less exposed. The weather conditions have been very variable, and the barometer has made large oscillations. In consequence of this the surface of the ocean has been far from level, and the difference has been noticeable even at places not remote from each other. Simultaneous observations of this kind, though difficult to be made, show how susceptible the surface of the sea is to slight changes of barometric pressure, so that, unless the range of tide is considerable, it is simply impossible to eliminate the effects of it. At Liverpool and Fleetwood this is accomplished without much difficulty, as no other ports have a more advantageous range of tide, and the height of water to be expected over the dock sill can alone decide the question whether at any particular date a ship is to reach her berth.

**James Pearson, M.A., F.R.A.S.**

Fleetwood, July 8th.

## WATER ANALYSIS — MANUFACTURE OF ALUMINIUM—WILLESDEN CANVAS — PYROLOGY — MINERAL SPRINGS NEAR LONDON.

[24497.]—"Cambrian," in query 56993, headed "Water Analysis (Qualitative)," asks for "a simple process whereby a sample of water can be tested qualitatively for sewage contamination and other impurities." Unfortunately, no thorougly satisfactory test of the sort exists or is likely to be devised. Besides, it is only by a quantitative application of a number of tests and a careful interpretation of their indication that a reliable diagnosis for sewage can be effected. For instance, in pure inland waters, not in the vicinity of salt beds, only very trifling proportions of common salt (chloride of sodium) are to be found, two grains per gallon of the water being about the maximum. But if a well water be contaminated with urine or similar impurity, the proportion of salt in the water will be considerably increased, and may rise to 30 or even 50 grains per gallon. In the case of ordinary town sewage, the proportion of salt is usually about 15 to 18 grains per gallon. Now it is clear that to detect the presence of salt proves nothing, but if the proportion be sensibly in excess of two grains per gallon, the water should be looked on with suspicion. Taken alone, however, the presence of an unusual proportion of common salt is usually insufficient to prove contamination, as it may have a perfectly innocent origin. If, however, the proportion of common salt in the unpolluted wells of a district be perfectly well known, a comparatively slight increase on the normal proportion will afford strong evidence of contamination. Again, fresh sewage contains a notable proportion of ammonia, which may be readily recognised by "Nessler's test"; but filtration through a very few feet of well aërated and porous soil will suffice to destroy the whole of the ammonia and oxidise it to nitrites and nitrates, though the water is probably little less dangerous than at first. Hence to ignore the evidence afforded by the presence of abnormal proportions of nitrites and nitrates in a water is extremely shortsighted. One of the "simple tests" which is repeatedly recommended is to "add a few drops of a solution of permanganate of potassium to a glass of the water, and note whether the violet colour of the reagent is destroyed." But nothing is usually said as to the strength of the permanganate solution, the exact number of drops to be used, or the quantity of water to be employed, and unless these conditions are prescribed and adhered to, the test has no practical value. Besides, a water from a shallow well may have had its sewage matter fairly well oxidised and destroyed during dry weather, but when a spell of rain comes the pores of the soil get filled up, oxidation can no longer occur, and the character of the water is changed materially for the worse. The hardness of water can be ascertained by a fairly simple process based on the addition of a solution of soap of known strength until a permanent lather is obtained. Details of the method are given in almost all books treating of quantitative analysis. Church's "Laboratory Guide," published by Van Voost, is the one I should recommend the querist to obtain.

The method described by "P. E. W.," on p. 418, in reply to query 56949, is not a process for the "Manufacture of Aluminium," and Webster's so-called "improvements" do not appreciably affect the price of the metal. They simply refer to the preparation of alumina, and the problem of reducing this cheaply to metallic aluminum is left exactly where it was.

"Willesden Canvas" (query 56989, p. 419) is prepared by passing ordinary canvas through a solution of oxide of copper (and zinc) in ammonia. This liquid has the property of dissolving cellulose, depositing it again on exposure to the air. The exterior of each fibre becomes agglutinated and is rendered completely waterproof and incapable of rotting. Paper of all kinds can be similarly prepared. By passing several sheets together through the cupric solution, and then between rollers, they become firmly united, and sheets of any thickness and as hard as teak can be obtained in this manner. The Willesden fabric appears especially suitable for constructing light buildings, tents, canoes, &c., and is also of service for foreign letter-paper and envelopes and probably for wrapping goods. It has more or less of a greenish colour owing to the copper it contains, but, in my opinion, the tint rather adds to its appearance. A recent visit to the Willesden works impressed me very favourably with the material, which appears capable of extended and very varied application. "K." should remember that the Willesden process is patented and very jealously guarded.

I have read with interest the letter on "Pyrology" (No. 24451, p. 412), as I do all the communications of Colonel Ross. He has shown so much patience and industry in working out blowpipe methods and devising new apparatus, that anything on the subject from his pen is certain to attract attention. On the other hand, I must protest against the accusation made by Col. Ross that any *animus* on the subject prevails amongst many English chemists. Chemists are only too glad to have useful additions made to their methods and tools, and if the processes of Col. Ross have not in all cases met with general adoption, he is himself largely responsible for the result. To give one instance, he complains of the scepticism of a "well-known London chemist" as to the constancy of composition attributed by Col. Ross to his ball of calcium borate. I fully agree with the unnamed chemist, that Col. Ross has never proved his case, although a few days' work would have sufficed for the purpose. It is, I believe, a fact, and if not *still* true Col. Ross will correct me, that the alleged constant composition of the ball has only been proved by operating in the blowpipe on 20 to 30 milligrammes of material. When Col. Ross has operated on reasonably large quantities in a platinum crucible, has definitely analysed the ball and the surrounding boric acid by processes the accuracy of which is generally accepted, and has published the results in the ordinary manner in some scientific journal, or before some society *competent to* criticise them, chemists will have their *attention* seriously directed to the matter; but while Col. Ross contents himself with arguing in a circle, and using new processes of unacknowledged adequacy to prove the truth of doubtful statements, so long are chemists likely to consider his case "not proven," and it is not to be expected that they will themselves go deeply into a matter which specially concerns Col. Ross, while he himself appears to be content to scratch the surface. I think Col. Ross does his unnamed correspondent an injustice in his attempted parody of his arguments, and, as Col. Ross appears to think it improbable that the publication and criticism of his letter will come to the writer's knowledge, I may remark that if the person who first observed the precipitation of silver nitrate by hydrochloric acid had neglected to prove the absence of silver in the mother-liquor, he would have neglected a precaution which would be obvious to most people.

Of the "Mineral Springs in or near London" (query 56975, p. 397), the majority have long been closed. The site of the old wells at Epsom was still pointed out twenty-five years ago, the Beulah Spa Gardens at Upper Norwood were closed thirty years ago, and, I believe, a swimming bath is still supplied by Bagnigge wells; of the Kensington spring I know nothing. Epsom wells yielded a water containing a notable quantity of magnesium sulphate, whence the name of "Epsom salts."

Sheffield, July 11. **Alfred H. Allen.**

## RAILWAY-SIGNAL RETURNS.

[24498.]—The Board of Trade returns relating to the railway-signal arrangements and systems of working on the 31st of December, 1884, have recently been issued, the details being given under two headings—(1) The interlocking and concentration of signal and point levers; (2) the systems upon which the lines are worked relating to the block system, &c.

The details are minute and voluminous, but the facts can be gathered from the following tables: No. 1 shows that the levers require "concentration" in 5,389 cases and "interlocking" in 5,189 instances; also, that no less than 3,130 pairs of "safety points" are requisite. From table No. 2 it will be seen that the total length of line open for passenger traffic was 17,933 miles, of which 13,822 miles were worked on the absolute block system. There are 366 miles of single railway upon which only one engine at one time, or two coupled together, are allowed: thus leaving a balance of 3,735 miles which are still worked upon inefficient principles and require the introduction of the absolute block system.

Summary No. 1.

| | Number of cases in which any passenger line is connected with, or crossed on the level by | | | | Number of cases in which the usual requirements of the Inspecting Officers of the Board of Trade have, or have not, been complied with in the following respects:— | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | Any other passenger line. | Any goods line. | Any siding. | Any cross-over road. | Concentration of signal and point levers | | Interlocking of signal and point levers. | | Addition of safety points in case of goods lines and sidings. | |
| | | | | | Have | Have not | Have | Have not | Have | Have not |

Leicester, July 4. Hon. Mem. A.S.R.S.

## SHORT-FOCUS REFLECTOR.—TO MR. WASSELL AND OTHERS.

[24499.]—Is there any inherent reason why a very short-focus mirror, say four or five times the aperture, if known to be truly parabolic, will not perform well as a Newtonian? May it not be that the very short focus mirrors that have not performed well were of improper figure? I have recently experimented with a 5in. mirror of only 25in. focus and with good results. Is it not, therefore, safe to attempt a 20in. mirror with a focus of 80in. or 100in.? What is the shortest focus Newtonian known of large aperture? With no chromatic error to trouble us, I do not see why a mirror of perfect figure should not give good results with very short focus. I found it easy to parabolise the short 5in.

**B. R. W.**

## THE CALORIE, OR FRENCH THERMAL UNIT.

[24500.]—Ch. Rabache, in letter 24396, page 365, has fallen into error as to the relative values of degrees Centigrade and degrees Fahrenheit. "Tubal Kain's" statement is correct: 1° C. = 1·8 F. But before converting degrees F. into degrees C., it is necessary to deduct 32 to reduce the F. scale to the same datum as the C. scale. As an example, take the common expression: "There were 8° of frost last night"—meaning the F. thermometer registered 24°; which, deducting 32, gives − 8° F. Convert these − 8° F. by "Tubal Kain's" value, and we have − 4·4° C., which is correct.

**Libra.**

## CURVES OF LARGE RADIUS.

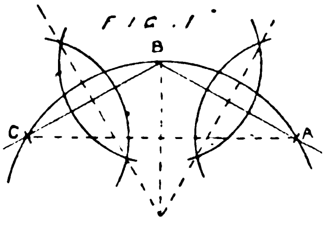
[24501.]—I have been asked by some of our friends to describe the way which I suggested to obtain "curves of large radius" sent in answer to a question which appeared some time since in "Ours." Should the Editor consider the description of sufficient general interest I am pleased to offer it.

In the geometrical problem, "three points being given, to find a circle that will pass through those points," if the given points are equidistant, and we find how much they differ from a straight line, we actually find the height of the arc of a circle required to pass through them.

I argued from this, if the angle made by the points be fixed, and this fixed angle be made to pass over the two end points A C, Fig. 1, the angular point will describe the circle; that is, it will pass over every point in the path of the curve sought.

We have thus the principle of an instrument as Fig. 2. We can fix it at any angle by the screw S working in a circular slot, and it has an adjustable pen supported by two points as a hinge to fall in the centre of the open hinge H (which is equal to the point B, Fig. 1). We are with it able to describe any curve, when we know the height of the arc required. To more accurately find this centre when adjusting the instrument, a cell was made to fit in the circle H, having a glass bottom, on which was drawn fine lines crossing at its centre. These crossed lines can therefore be made to cover any point found, which is the height of the required arc. The cell being afterwards removed, the pen can be adjusted to fall on the same point that was covered by the cross lines.

FIG. 1



To measure the height of arc correctly to the third place of decimals:—On a stretched length of paper draw a straight line, say 7ft., and on the line fix two pins 6ft. apart; on the point of bisection between the pins raise a perpendicular, and divide this perpendicular into inches and tenths of an inch, numbering them upwards. Have the two rules as in Fig. 3. On the lower one, D, a scale is graduated from its centre towards the left hand 10in. long, divided in inches and tenths. The upper one, E, has its upper edge as thin as possible, and the distance between the pointers marked on it is 10in. At one pointer this rule is $\frac{9}{10}$ of an inch wide, and at the other pointer $\frac{10}{10}$, or one-tenth wider than the other. It will be seen, therefore, that every inch the first pointer on rule E slides over rule D, the upper edge rises at the starting point $\frac{1}{100}$ of an inch, and every $\frac{1}{10}$ of an inch on rule D the pointer passes, the upper edge rises $\frac{1}{1000}$in. To measure, therefore, the height of arc on the graduated perpendicular line, the inches and tenths are first found on that line; the pointer at the upper edge of rule E is then placed on that tenth, which is the first decimal; the rule E is then slid along the rule D; the pointer at the inches marks the second decimal, and at the tenths of the next inch the third decimal. The upper edge of rule E will then show on the perpendicular the height of the arc

FIG. 2

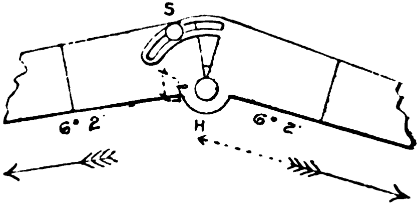


FIG. 3

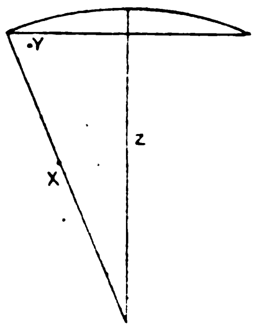
FIG. 4



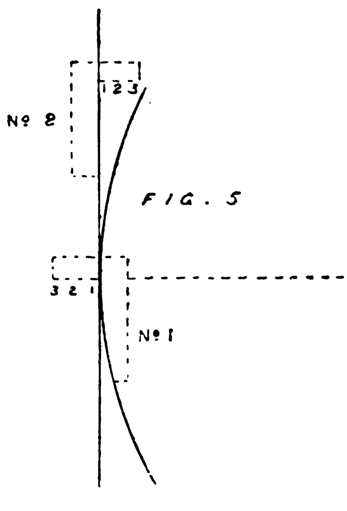


FIG. 5

required. The accuracy of the result will depend on the accuracy of manipulation.

When the height of arc is thus found, the instrument must be adjusted correctly to that point by the cross lines on the cell, and the circle described by passing the instrument from one point to the other, A to C, Fig. 1.

The table of heights of arc was calculated thus: (Euclid, Book I. Prop. 47.) The square upon the side subtending a right angle is equal to the sum of the squares of the other sides. Therefore, in Fig. 4, subtracting the square of the side Y (which is half the chord of the arc) from the square of the radius X will leave as remainder the square of the other side, Z. The root of this deducted from the radius X will leave the height of the arc for that radius. This was done for each radius to form the table.

TABLE SHOWING THE HEIGHTS OF ARCS FOR EVERY FOOT RADIUS BETWEEN 5FT. AND 100FT., THE CHORD OF ARC BEING ALWAYS 6FT.

| Radius in Feet. | Height of Arc in inches. | Radius in Feet. | Height of Arc in Inches. | Radius in Feet. | Height of Arc in Inches. | Radius in Feet. | Height of Arc in Inches. |
|---|---|---|---|---|---|---|---|
| 5 | 12 000 | 29 | 1·867 | 53 | 1·020 | 77 | ·702 |
| 6 | 9 645 | 30 | 1·804 | 54 | 1·000 | 78 | ·692 |
| 7 | 8·104 | 31 | 1·742 | 55 | ·982 | 79 | ·684 |
| 8 | 7 005 | 32 | 1·690 | 56 | ·964 | 80 | ·675 |
| 9 | 6·176 | 33 | 1·639 | 57 | ·948 | 81 | ·667 |
| 10 | 5·527 | 34 | 1·591 | 58 | ·931 | 82 | 658 |
| 11 | 5·004 | 35 | 1·545 | 59 | ·915 | 83 | ·650 |
| 12 | 4·572 | 36 | 1·502 | 60 | ·900 | 84 | ·643 |
| 13 | 4 210 | 37 | 1·463 | 61 | ·885 | 85 | ·636 |
| 14 | 3·909 | 38 | 1·423 | 62 | ·871 | 86 | ·628 |
| 15 | 3 636 | 39 | 1·387 | 63 | ·858 | 87 | ·620 |

| 17 | 3·201 | 41 | 1·318 | 65 | ·831 | 89 | ·607 |
| 18 | 3·021 | 42 | 1·287 | 66 | ·818 | 90 | ·600 |
| 19 | 2·859 | 43 | 1·257 | 67 | ·806 | 91 | ·593 |
| 20 | 2·715 | 44 | 1·228 | 68 | ·792 | 92 | ·586 |
| 21 | 2 584 | 45 | 1·201 | 69 | ·783 | 93 | ·580 |
| 22 | 2 466 | 46 | 1·174 | 70 | ·771 | 94 | ·574 |
| 23 | 2·358 | 47 | 1·149 | 71 | ·760 | 95 | ·568 |
| 24 | 2·258 | 48 | 1·122 | 72 | ·750 | 96 | ·562 |
| 25 | 2·168 | 49 | 1·102 | 73 | ·740 | 97 | ·556 |
| 26 | 2·084 | 50 | 1·081 | 74 | ·729 | 98 | ·550 |
| 27 | 2·006 | 51 | 1·059 | 75 | ·718 | 99 | ·545 |
| 28 | 1·934 | 52 | 1·039 | 76 | ·710 | 100 | ·540 |

To find the parabolic curve for a long focus:—As the parabola is "a curve whose path is equidistant from a fixed point and a fixed straight line," at the centre of the curve the two distances meet at that point. Draw, therefore, the straight line (the directrix) at that point, and, touching that point, draw with the instrument a curve with a radius equal to the distance of the focus of the desired parabola; we have then only to deal with the path of the remainders of the distances. This will be immediately appreciated by the following suggestion:—

Fig. 5. Make two thin cardboard templates, one to the curve as No. 1 in the figure, the edge graduated to the left, and another graduated to the right as No. 2. By making these overlap and pass along, the one on the directrix and the other on the curve, as they can be easily made to do guided by two small pins placed on the lines and on the curve, wherever the distances coincide on the two graduated edges will be a point in the required parabola. From these points the parabola can be drawn.

I trust this description is clear. The instrument would be useful to surveyors and civil engineers, and could of course, be made on a smaller scale, and a table calculated to a shorter chord. This one was made to fulfil the conditions required in the "E. M." J. S. B.

## AUTOMATIC MUSICAL INSTRUMENTS.

[24502.]—I HAVE read with the greatest interest the letter from Mr. F. H. Wenham, describing his appliance for playing the piano, and, being myself subject to attacks of *automatic fever*, should very much like to have a little further information.

Would it be encroaching too much on Mr. Wenham's good nature to ask for a drawing and description of the principal action? His idea seems to solve the difficulty of making at once a portable and effective substitute for a pianist, and one in which the command of piano and forte passages are well under control. The music, too, being of cartridge paper, can be made very cheaply. My arrangement for cutting cards, described in the "E. M." some time since, will cut easily six thicknesses of cartridge paper, and not being hinged, like the card music, it could be made at less than one-fourth the cost, or something like 6d. per yard.

I have heard and read vague rumours of a company called the "Miranda Pianista Company"; but can anyone tell me if there is such a company, or is it but "the hare-brained chatter of irresponsible frivolity"? Rook.

## USEFUL AND SCIENTIFIC NOTES.

**The Patent Office.**—The Comptroller-General of patents, designs, and trade marks, issued the other week in the form of a Parliamentary paper his report, the second since the passing of the Act of 1883. That the new Act has worked well in the interest of inventors may be seen from the fact that the number of applications for patents, which had risen with some variations, almost constantly in the course of 30 years, from 1,211 in the year 1852, to 6,241 in 1882, leaped with a bound to 17,110 in 1884. There was a slight depression in 1883, possibly on account of the change of the law, which makes last year's numbers the more remarkable. The increase is in fact as between the years 1883 and 1884, no less than 195 per cent. Seventy-nine per cent. of the applications were made by persons resident in the United kingdom, namely 12, 356 being residents in England and Wales, 901 in Scotland, and 254 in Ireland. Of the rest the largest numbers were from the United States, 1,181, from Germany 890, and from France 788. Residents from 27 other countries also made application to the office, 13 such countries being British possessions, from which 175 applications were made, and three, it my be added, were made from Egypt. Only three appeals were made in the course of the year against the decision of the Comptroller, so that it may be taken that his decision is almost invariably satisfactory to applicants. The greatest number of applications made in any month was in January, 2,499; the smallest in August, 992. The greatest numcer made in any single day was, as might be supposed, on January 1, 266. The total number of patents sealed upon the 17,110 applications will not be known before next year. The number of readers who frequented the Free Library of the Patent Office in 1884 was 39,508, as against 32,748 in the previous year. Sets of the publications of the office have been sent to 46 towns, to a large number of public offices, and seats of learning in the United Kingdom; to nine British colonies, and to nine foreign States. Complete series of abridged specifications have also been sent to nearly 280 mechanics, literary and scientific institutes in various parts of the United Kingdom and the United States. The number of designs registrated in 1884 was 19,515, as compared with 17,166 in 1883; and the number of trade-marks applied for was 7,104, to 4,105 in 1883. The receipts of this office amounted to £103.827, of which £88,996 was for patents' fees, £3,477 for designs' fees and stamps, £7,014 for trade-marks' fees, and more than £4,000 for the sale of publications. The chief payments made were £36,225 for salaries—all of which are set forth in detail in the report—and £17,000 to Messrs. Eyre and Spottiswoode paid for printing. There was a surplus income of nearly £40,000. Tables are added showing the different classes of designs and trade-marks, with the fees paid for each.

**Interior Temperature of the Earth.**—The German Government is having a deep shaft sunk near Schladebach, with the object of obtaining various kinds of scientific information, and especially trustworthy data concerning the rate of increase of the earth's temperature as we descend into the interior. The excavation is being carried on by a diamond-tipped borer driven by water. So far back as the beginning of this year the shaft had reached the depth of 1,392 mètres, which is believed to be the lowest depth yet reached by boring. The temperature at successive stages is ascertained by an ingenious instrument which serves as a special thermometer, the principle of construction being the fact that as the heat increases the mercury will expand so as to flow over the lip of a sufficiently short open tube in greater and greater quantities. The measurement of the differences of those overflows will give the rate of increase of the temperature. It has been ascertained that the temperature at the depth of 1,392 mètres was 49deg. centigrade, or 120deg. Fahrenheit. If the temperature increases regularly at this rate, the boiling point of water ought to be reached at a depth of 3,000 mètres, and at 75 kilomètres we should find the heat at which platinum melts. This would go to show that the earth's crust cannot be more than one-ninetieth of its radius.

**How to Become a Successful Amateur Photographer.**—Messrs. Lancaster and Son have just issued the tenth thousand of their sixpenny handbook, "How to Become a Successful Photographer." Every amateur who does not already possess it should obtain a copy. The directions are so clear and comprehensive, and the size so handy, that nothing is left to be desired.

## REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[56061.]—**Vapour Density.**—I hope M. Ch. Rabache will not deem me discourteous when I say that I must decline to enter into a discussion on this subject with him. He is evidently to chemistry very much what Mr. Hampden is to astronomy—a paradoxist of a very pronounced type, with whom argument is useless. I have a lively recollection of the letters, five-and-twenty pages long, with which he favoured me some years ago.—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56314.]—**Strength of Gear Wheels.**—To "GLATTON."—I do not want the weight to swing at the end of a lever, but probably I ought to have said hang, as it is to be, so as the chain or rope may nearly touch the roller it is wound upon; it is to be raised slowly.—C. B.

[56439.]—**Separating Potash and Magnesia (U.Q.)**—Potash and magnesia cannot exist together in solution. If the barrel contains only a little water, it will be better to add sufficient, and then filter. The potash will be dissolved, and will pass through the filter. Evaporate the filtrate, and the potash will be recovered. Well wash the precipitate on the filter (adding the washings to the potash solution), dry, and ignite.—ALTO PETIT.

[56440.]—**Warnerising (U.Q.)**—It consists in treating cloths with a specially-prepared oil. As well as I can now remember, this oil is a hydrocarbon oil from which the free acid has been removed by distillation. Full particulars will be found in the specification at the Patent Office, taken out, I think, in the name of Mrs. Eliza Warner. At the time I took a note of the number of the patent, but cannot at present lay my hands on it. Should "R.M." require it, and state so, I shall search further for him with pleasure.—ALTO PETIT.

[56500.]—**Gravity Leclanche Batteries.**—The querist will find a drawing of same, with remarks on its working, in Roberts's lecture on "Batteries" in Vol. VI. of the *Journal* of the Society of Telegraphic Engineers, page 257. Should he be unable to see the book, if he will advertise his address, I will send him a tracing with pleasure.—ASSOC. SOC. TEL. ENGS, Birmingham.

[56606.]—**Ink for Rubber Stamps.**—I notice one or two slight misprints in my reply last week (p. 415). "Buryed" should be "brayed" (i.e., "thoroughly incorporated"). Also water-*glue* should be water-*glass*.—PERCY W. STANLEY, 119, Manchester-road, Poplar, E.

[56620.]—**Steam-Carriages.**—I have seen the steam tramway locomotives to which Mr. E. F. Baker refers, p. 415. I even took stock of the line while it was being laid: it is, I believe, the first to be worked regularly in London; but though London is a big place, it is not the United Kingdom, and there are as good arrangements to be seen in the "provinces," as they are called. But steam tramways have nothing to do with steam carriages. "Progress No. 3" (wonder if this is the original "Progress") thinks that "other people" will dub him crazy when he says he is preparing to build a train of five vehicles to be propelled by the pistons' direct pressure on the road, such pressure being obtained from the explosion of gas to be ignited by electricity. I should imagine that "Progress No. 3" has formed a correct opinion of what "other people" will think of his scheme; but then I studied the rudiments of mechanics some years ago, and no doubt they are much improved. By the way, I am not quite sure that the notions of "Progress No. 3" are new; but I am sure that "ridicule" would be utterly wasted on them—at all events "until our ideas are better comprehended."—NUN. DOR.

.[56620.]—**Steam-Carriages.**—In connection with this subject, I would refer to "B. B." (24455, p. 412) on "Crank Axles," in which he speaks of the usual practice of each pair of wheels being fixed in rigid connection with its fellow. In my sketch of a train carriage on p. 415, I mention its capability of easy turning, which is obtained by each wheel working quite independent of others, and turning on the bearing point of the tire, the load resting on a pivot over each wheel; it will then turn in any direction with the greatest ease. This avoids the use of any axletree as at present used; but whether the wheel should revolve on the spindle, or be fixed and revolve on side bearings, is left for after determination. I should also avoid steel-plate springs, such being often a great source of noise. E. F. Baker, p. 415, in stating that tramway locomotion is done daily "on" common roads, I suppose him to mean the tramway is laid on the road, but the locomotion of the engine and cars takes place by trammelled wheels "on" grooved iron rails, and my contention is that on a hard level surface and speed under ten miles per hour, the flat-tire vehicle has 25 per cent. advantage over the flange and groove system. Much information on this subject is contained in "Tramways: their Construction and Working," by Mr. D. K. Clark, two vols., price 30s. As to horse-labour for tramways, p. 261 says, "that the life of a horse is four years on tramway service, and four and a half years on omnibus service." Page 263 reads "The proportional number of carcases and living horses sold by one company during one year was 1,208 carcases and 676 living horses, showing that two-thirds of the horses that were sold either died or were worn out in the service, and that a third were sold as only fit for agricultural work—too weak, or afflicted with bent knees." The number of horses "used up" in London (only) is supposed to range between 400 and 500 per week, or between twenty and twenty-five thousand per year; and yet we call this a Christian country—but the horses would say, Where are the Christians? On p. 351 is an account of experimental proof of the tractional resistance of a tramcar in France. The length of line traversed was a third of a mile, on a level, at 7½ miles per hour. The removal of two flanges was accompanied by a reduction of the tractive resistance by one-third. Encouraged by the results, another flange wheel was removed, running the car with only one flanged wheel and three flat-tire wheels; the result was that the resistance was reduced a half as compared with the original car with four flanged wheels. The comparative difference in cost of motive power on tramways is shown on p. 417 as 4d. per mile run for steam motive power, as against 7½d. the cost for horse power; other accounts say 5d. per mile for steam, against 9d. for horse power. In a late prospectus of the North London Tramways Company, they state they have 15 steam-engines of an approved type in course of delivery. The Croydon and Norwood Tramways Company is to be worked by a fireless locomotive, under the Dusseldorf system. It is said the engine can be driven up a gradient of one in twelve and a half with nine tons behind it with ease. Some of the advantages to be gained by using mechanical power on iron bearing can be reckoned by taking the average cost and work done by one horse during one week on macadam road, the cost of the horse being 20s. per week of six working days, or 3s. 4d per day of eight hours at three miles per hour. During the eight hours he will draw a load of one ton weight for a distance of 20 miles equal to 2d. per ton per mile, and by using mechanical power at one-half less cost, it would reduce the charge to 1d. per ton per mile; then, by use of the iron rail, the cost of the same work would be again reduced three-fourths, making a total reduction in cost of motive power for either goods or passengers of 87½ per cwt. Pedal power machines on iron bearing, where gradients are slight, would carry a load of 8 to 10 cwt, without any charge for motive power, the driver himself propelling the machine. If any reader of "E M." can detect an error in my statements, and will point it out, I shall be pleased to "sit corrected." —PROGRESS (4).

[56650.]—**Lead Burning.**—I have used Brigg's patent soldering and lead-burning machine repairing large bilge pipes of telegraph s.s. *Minia*, and may say there is no zinc or vitriol required, and cannot be damaged, as its working parts are all protected, and no gas can escape, as it only generates gas when in use, and then enough heat can be got to burn any lead or melt solder for any size of plumbers' wiped joint or braze ¼in. steel telegraph wire or expand cable links, or iron nuts for engineers, and has been strongly recommended for economy, safety, and cleanliness.—WM. MAN.

[56650.]—**Lead Burning.**—Referring to the repeated correspondence appearing in your journal for the last four years between plumbers and lead-burners, and finding that one of your correspondents in your issue of July 10th has referred to our patent machine, as shown at the International Inventions Exhibition, Stand 220, South Gallery, North Court, we would thank you for the information of the trade to take notice of a few particulars relating to the same. In the first place, under the present system spelter and acid are required to generate the gas, when an air-pump or bellows is required to force it to burn the lead, with two tubes running into one with regulating cocks; this machine is more or less dangerous, the flame being liable to run back. We have seen more than one accident happen by the machine exploding. It is more than twenty years since we commenced working one of these machines, and by repeated experiments for the last four or five years have succeeded in making a machine which requires no acids or spelter, neither does it require any attention when at work, for when it is charged the gas does not generate until the pump is set at work. The machine consists of one cylinder and only one tube and blow-pipe, with regulating cocks which may be left open without the gas escaping, and is ready to burn lead from 4lb. to ¼in. thick at any moment, or to make plumbers' wiped or other joints without the use of forge or heated irons, and may be carried anywhere, not being heavy. It is particularly noted that the flame is perfectly clean and dry, and does not discolour the work. We have many testimonials from engineers testifying as to its superiority over the old system as far as safety, cleanliness, and economy are concerned. Knowing Mr. Davies to be a thoroughly practical engineer, we should esteem it a favour if he would view our exhibit at the Inventions and give his opinion of the same through the columns of your valuable journal.—BRIGGS AND CO., 58, Rokeby-street, Stratford, London, E.

[56676.]—**Free Reeds.**—The reply furnished on p. 393 to this query might well be added to the list of instances in which "presumption" follows "ignorance." I consider it, therefore, my duty to point out the misconception of "G. L. B." on p. 393. If "G. L. B." will refer to the original query, which appears on p. 157 (query No. 56400), he will soon discover the mistake he has made with regard to the exact requirements of the querist. The querist there asks distinctly, "How can I tune reeds?" and evidently does not merely require to know how to bring or file reeds up to a standard pitch. What on earth is the use of telling a private individual how to file reeds up to pitch, when that has already been done before they (the reeds) are purchased? May I also ask "G. L. B." of what use is the employment of a flutina bellows, as suggested in query No. 56676, for the purpose of tuning reeds? In the pages of "Ours," at least in musical matters relating to keyboard instruments, we want more practical information and less theoretical humbug and misconception, both with regard to queries and replies. Some queries are so thoughtlessly worded, and carelessly arranged, that a reply, or replies, of a somewhat similar character are bound of necessity to follow as a natural consequence. "G. L. B." may now learn that the querist does not require to know how to file reeds to pitch, but how to tune reeds. This I am fully aware of, in consequence of a private letter which I have received from the querist, and to which I replied by post. The query, No. 56676, which is addressed to me, was sent to the Editor for insertion afterwards, and the querist in this instance also changed his title, a fact which may partly account for "G. L. B.'s" misconception. The foolish ideas referred to by me in my last reply is simply the querist's notions of being able to tune reeds by the aid of a flutina bellows, as expressed in the query, combined with ideas equally absurd which were expressed in his private letter, and which are at present unknown to "G. L. B." I trust this explanation will suffice.—G. FRYER.

[56679.]—**Supported Beam.**—If in a uniformly loaded beam there is a shearing action at the centre, will "Bacchus" say what this shearing force is in terms of the load? Is the "correct answer" the one which the examiner expects to receive, any other being rejected? If so, the question is simply a catch.—J. S. C.

[56703.]—**Algebraical Problem.**—The expression $\underline{|r}$ (factorial $r$) means the product of the integer numbers up to and including $r$. For instance, if $r = 6$, then—

$$\underline{|r} = 1 \times 2 \times 3 \times 4 \times 5 \times 6 = 720$$

The number of combinations of $n$ things taken $r$ at a time is (as stated on page 309)—

$$\frac{n\,(n-1)\,(n-2)\,\ldots\ldots\ldots(n-r+1)}{\underline{|r}}$$

From the conditions of the problem, the last term in the numerator of the above expression must be 10, because it is stated that the number of permutations $r$ at a time is to the number $r - 1$ at a time as 10 : 1. Thus we get—

$$\frac{10}{\underline{|r}} : \frac{1}{\underline{|r-1}} : : 5 : 3$$

multiplying out we have—

$$30\ \underline{|r-1} = 5\ \underline{|r}$$

$$\text{or } 6\ \underline{|r-1} = \underline{|r}$$

that is factorial $r - 1$ needs to be multiplied by six to make it $= r$, and $\therefore r = 6$.—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56739.]—**Books.**—"Student" should procure the syllabus, and attend one of the science classes, the teacher of which will be able to recommend books. The list he requires would be a tolerably long one, and would of necessity partake somewhat of the nature of an advertisement. The "tip" is to read up such books as are known to be used by the examiners.—S. K.

[56751.]—**Portrait Drawing in Crayons.**—This query is really a question about enlarging photographs. That has been answered many times. See, for instance, p. 302, No. 923, p. 119, No. 1019; and look through the indices of back volumes. If not available, procure one of the cheap and handy guides to photography. They mostly contain chapters on enlarging.—AN AMATEUR PHOTO.

[56754.]—**Filtering Water.**—This querist will not obtain a better filter for his purpose than that made of broken hard-burnt stock bricks. He should have two tanks—one to be at rest and dry while the other is working, and should clarify the water before passing on to the filters by taking it through screens of coarse canvas and afterwards felt. The bricks, broken up to pieces about the size of Spanish nuts, will thoroughly clean any water, if the latter is passed on to them freed from its more solid impurities.—ESSAR.

[56758.]—**Friction Clutch.**—These are well-known mechanical devices. One is illustrated on p. 28, Vol. XXXVIII.—E. G. M.

[56781.]—**Telegram Codes.**—Dr. Algar's is a good one, and is very generally used; but where it is to be obtained I do not know. Try Effingham Wilson, Royal Exchange. If you have only a few correspondents, you might easily draw up a code of your own, taking care to choose words which are not likely to be transmitted so erroneously as to lead to mistakes. That is the merit of Dr. Algar's code: he has chosen words to represent all sorts of commercial messages, which are so different that there is not much likelihood of their being mistaken for others. With a good code one can send, say, ten "messages" in the shilling telegram, for, if it is understood, the word "corn" would suffice for a broker to buy 1,000 bushels of wheat at a certain price.—S. R.

[56791.]—**Telephone Law.**—I am afraid this querist must study the decisions already given in the law courts, and make the best of them he can. The English Mechanic telephone is free, because that has been disclaimed.—NUN. DOR.

[56792.]—**Coal.**—Coal, being principally carbon, is a conductor; but it comes below the metals.—S. E.

[56793.]—**Seltzogene, Leaky.**—The top is probably cemented on with best plaster of Paris mixed with alum water.—ESSAR.

[56796.]—**Boiler.**—Has not "Invicta" made a mistake in the weight for safety-valve? Diam. valve, $1\frac{3}{16}$in.; area, ·518; length of lever, 5in.; fulcrum to centre valve, ¾in.

$$\frac{\cdot 518 \times 75 \times 24}{5} = 1 \cdot 86$$

= 30oz. nearly.—W. W.

[56813.]—**Fracture of Water-gauge Tubes.** "Bacchus" says he has never known an iron wire to scratch a glass tube and it is certainly not the means usually employed to break them. This is negative evidence one way—which is no good at all —and positive the other—which is readily contradicted by innumerable queries and replies in the forty volumes of the ENGLISH MECHANIC already issued. I have those forty volumes, and if I have, as your correspondent courteously expresses it, "floundered out of my depth," I am sure I have done so in good company. I am much afraid that "Bacchus" has no depth at all; but I congratulate him on the immunity he seems to have enjoyed from fractured gauge tubes. I thought every one knew the simple fact that glass tubes often "go" in a rather unaccountable manner.—NUN. DOR.

[56871.]—**Whitewashing.**—Get three or four quarts of skimmed milk and mix it up with the water and lime; I'll assure you that it won't come off for a while.—A YOUNG YOUNGSTER.

[56875.]—**Thymol.**—The two varieties of this substance are ($\alpha$) Thymol, obtained from oil of thyme by fractional distillation, which forms crystals; and ($\beta$) Thymol, prepared artificially from cymyl-sulphurous acid, which is a yellow viscid oil. "Novice" is evidently using the former variety. Both are isomeric with canacrol.—WM. JOHN GREY, F.C S., Analytical Chemist, Newcastle-on-Tyne.

[56885.]—**Potato Cleaning.**—I have been looking in back numbers for a machine, much used in Lancashire towns, which was described and illustrated some time back, but I cannot now find the number to refer you to; perhaps our kind Editor will do so. It consisted of an open cane-work basket with stout projected rim, which fitted down into a tub of water, the rim resting on top of tub; from the bottom of this basket a spike projected upwards. The other part was a circular-board brush with a hollow stem and a winch handle. The brush was stout reed, similar to an ordinary yard brush, which are set in bottom face. When in use the tub is three-parts filled with water, the basket put in, the potatoes put in the basket, the hollow stem of brush put on to the spike, and several sharp turns given to it; the basket is then lifted up, the water and skins run through into the tub, and if the potatoes are not all clean enough shake them up and repeat the operation. Perhaps an enlarged and improved make on this plan would answer your purposes.—J. I. S.

[56881.]—**Observatory Dome.**—The following sketch, I think, should make the construction of his proposed observatory dome a very simple matter to

"W. T. C." The foundation for your dome could be constructed of light planking. I would prefer teak wood, as it is the most durable, or, say, an iron plate of ¼in. thick; if you use the iron plate you would do better to have it in two plates, and strapped at its edges by a plate-strap on the inside, and by an angle-iron bar on the underside. You will find this latter method stand the weather much better, especially if it is placed in an exposed position. The size of the bottom angle-iron should be about 2in. by 1½in. by $\frac{3}{16}$in.; this bar is attached with its (2in.) flange to the bottom of the dome, and the side plate (6in. high, ⅛in. thick) is riveted to the 1½in. flange of the angle-iron bar. The size of rivets required for this will be ¼in. in diameter, and spaced 5 diameters apart. Two angle-iron bars cross each other at right angles at the top of the dome, a slot being cut out of the one that passes over the other; and on the top of the dome is placed, for strength, a plate, 2ft. in diameter and ⅛in. thick.—Dumbarton.

G.G. A PLATE 5" BROAD AND ⅛" THICK WHICH IS RIVETTED TO THE OUTSIDE FLANGE OF THE ANGLEIRON BARS
ANGLE IRON 1½ x 1½ x 5/16

[56891.]—**Shocking Coil.**—I forgot to mention the size of secondary wire. It is No. 36, silk-covered, and the connections are from the binding-screw to the switch, and through the primary coil and out to the electro-magnet contact-breaker, and then down the platinum screw pillar and back to the other binding-screw. The secondary wire from the binding-screw through the reel and to the switch, and to the other binding-screw I have connected a piece of wire to the secondary about ¾ of the reel, and then to the other part of the switch to give a weaker power.—I. O. G. T.

[56914.]—**Socket Joint Making.**—I am extremely obliged to Mr. A. Richardson for his reply; but I have not got exactly at what I should like. I am afraid white and red lead, &c., would not make a sure cure of it, and the second recipe, no doubt, would do very well; but Mr. Richardson says, caulk with it. Now, owing to certain fixtures, which would be very expensive removing, we cannot get to caulk them, and anxiously wish for something to point up, like cement, that would make them perfectly tight, remembering that there is the weight of water from pipes two stories higher than the faulty or leaky joints. Can Mr. Richardson or anyone help me any further, as I really wish to make a good job of them.—Anxious.

[56935.]—**Choke-Damp.**—Choke-damp is the term applied to the $CO_2$, or, more correctly, to the mixture of $CO_2$ and N produced by the explosion of the marsh gas in a coal mine. The equation is—

$$\underset{\text{firedamp}}{CH_4} + 4\underset{\text{air}}{(O + 2N_2)} = CO_2 + 2H_2O + 8N_2$$

Two volumes of $CH_4$ need (about) twenty volumes of air for complete combustion.—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56942.]—**Electro-magnet.**—"D. W." must not expect to magnetise even a sewing needle with a magneto-electric machine, as the currents from it are alternate. I believe there is a special bell that is rung from such a machine, called the magneto-bell.—Fra. Broadbent, Hammersmith.

[56948.] — **Gas - Producing Apparatus.**—Fletcher's apparatus makes capital heating gas, but you will want the pressure of air; but having had some experience, let me warn you as to the use of this gas. Fletcher puts a good safety-chamber to his generator, and all is safe unless you leave some of the gas past the safety chamber, and then have a light back. This gas is more dangerous as compared with common gas.—Z. Y. X.

[56930.]—**Three Problems—Errata.**—In my reply to this query on p. 417, there is an obvious arithmetical blunder at line 15, where $\frac{16}{192} = \frac{1}{12}$ and not $\frac{1}{18}$ as there stated; consequently, the odds are 11 to 1 against the event, and not 17 to 1. Also at end of reply, by a printer's error, $\frac{1}{24} \times \frac{1}{64}$ stands instead of $\frac{1}{24} + \frac{1}{64}$ the correct reading.—C. Planck.

[56932.]—**Periphery of Ellipse.**—In reply to "A. S. L.," the radius of curvature can be found from the expression $\frac{(1 + p^2)^{\frac{3}{2}}}{q}$, where $p = \frac{dy}{dx}$, and $q = \frac{d^2y}{dx^2}$; in the ellipse $\frac{dy}{dx} = -\frac{b}{a} \cdot \frac{x}{\sqrt{a^2 - x^2}}$ and $\frac{dy^2}{dx^2} = -\frac{a\,b}{(a^2 - x^2)}^{\frac{3}{2}}$, the result being

$$r = -\frac{(a^4 - a^2x^2 + b^2x^2)^{\frac{3}{2}}}{a^4\,b},$$

*a* and *b* being semi-axes. Now, to find the co-ordinates of the extremity of the radius of curvature for any point *x*, *y* of the curve, call the co-ordinates of the extremity X and Y; then X will be found to be $\frac{a^2 - b^2}{a^4}x^3$, and Y will be—

$$-\frac{a^2 - b^2}{a^3\,b}(a^2 - x^2)^{\frac{3}{2}}$$

Then, if we require an equation between X and Y to represent the curve formed by the ends of all the radii, we must eliminate *x* from these two equations, and we get—

$$Y = \frac{1}{b}\left[(a^2 - b^2)^{\frac{2}{3}} - (a\,x)^{\frac{2}{3}}\right]^{\frac{3}{2}}$$

I have not given the various steps required to find these equations, as they are troublesome to print; but I can give a sketch if required. Now, about the series for calculating the periphery of the ellipse, I have used the following for the whole periphery—

$$2a\pi\left\{1 - \frac{1}{2^2}e^2 - \frac{3}{(2\,.\,4)^2}e^4 - \frac{3^2\,.\,5}{(2\,.\,4\,.\,6)^2}\,.\,e^6 - \frac{(3\,.\,5)^2\,.\,7}{(2\,.\,4\,.\,6\,.\,8)^2}e^8 - \&c.\right\}$$

where *e* is the eccentricity of the ellipse, and is equal to $\frac{\sqrt{a^2 - b^2}}{a}$. This series is not difficult to work if, instead of working out each term, we act as follows. If we call the term involving $e^2$ the first term, ignoring for the present the 1 at the commencement of the series, then suppose we have calculated any term, say the *n*th, the next term can be found by multiplying the *n*th term by

$$\frac{(2n - 1)\,(2n + 1)e^2}{(2n + 2)^2}.$$

I have calculated with this the periphery with axes 8 and 4. I have not taken more than five terms; the result is 19·4058.—M.I.C.E., Bath.

[56949.]—**Aluminium** can be obtained from cryolite. $Al_2Fl_3\,3\,NaFl + 3\,Na = 6\,NaFl + Al_2$. Al = 13·10 per cent. A short time since I obtained Al from $Al_2O_3$ in a simple and inexpensive way without the aid of sodium, and also Ca from CaO, which contains 71·42 per cent., by the same process, a beautiful white metal which it appears to me is destined to become a most useful metal some day, as it will not oxidise. It is advertised in Birmingham at 2s. per grain = £700 per lb. Can any person inform me of the present price of Al?—F. W. G., Wolverhampton.

[56949.]—**Manufacture of Aluminium.**—This metal is made at Salindres by M. Pechiney. The process consists of three stages—1st, alumina is prepared from bauxite; 2nd, the alumina is converted into double chloride of aluminium and sodium; 3rd, this salt is reduced by means of metallic sodium. The method is practically the same as that worked out by St. Claire Deville, and is necessarily very costly on account of the price of sodium, and the chief item in the cost of sodium is the small iron vessels in which the distillation is carried on. These vessels wear out with such rapidity that their cost is fully half the total cost of sodium. Some time ago a correspondent of the "E. M." spoke of having succeeded in reducing $Al_2O_3$ by sugar. I wrote stating that the reaction was impossible, a statement to which he took grave exception; but I have never heard anything of the cheap aluminium which he predicted.—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56951.]—**Dynamo.**—To Mr. Bottone or "W. H. E."—I should like it to be able to run 10 c.p. lamps, and, therefore, the E.M.F. not less than 20 volts. Ten lamps would be sufficient. Definite instructions would be esteemed.—Carnforth.

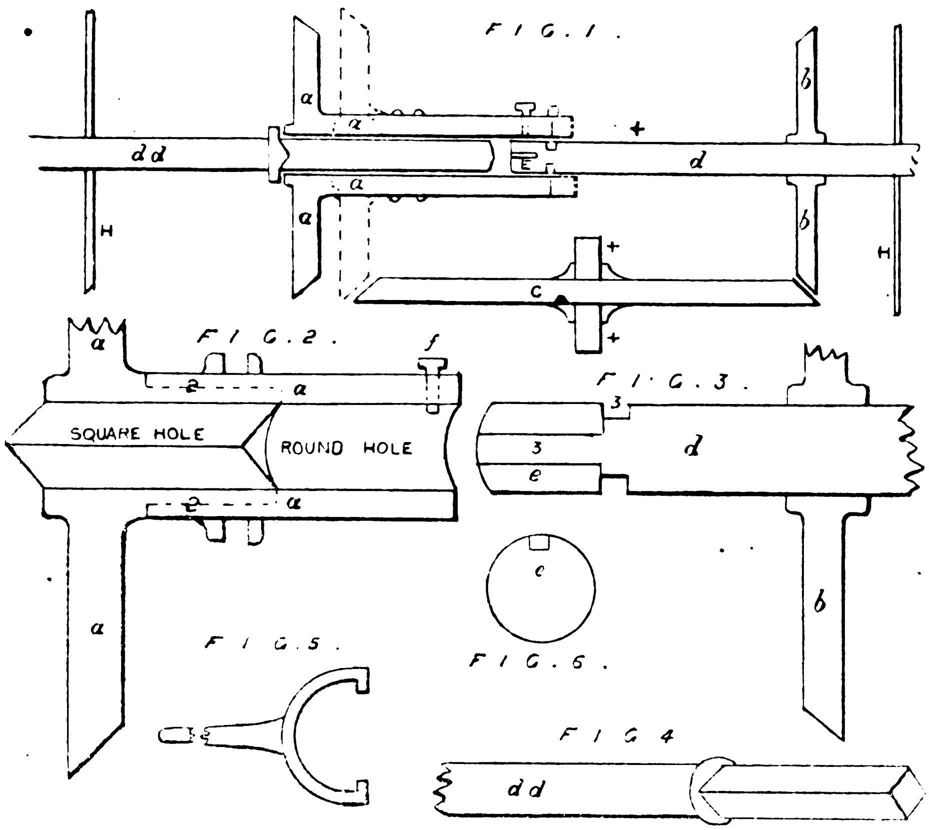
[56955.]—**Photography.**—"B. Sc." should not give such uncertain advice. A wet plate can be developed, fixed, and washed in the same time it would take to develop a dry plate only. The principle advantage of a dry plate is its quickness. Putting that on one side, there are many advantages in a wet plate for studio use. I use both in a portrait studio, and say what I know.—Gwent.

[56956.]—**Ball Bearings.**—I think Mr. Chas. Hosken is mistaken about gun-metal bearings. What he says about an engine is quite true; but does not apply to a bicycle, as he would know if he were a practical rider. The grit of an ordinary road would cut them to pieces in a week—in fact, I have known them so done; whereas, in ball bearings, the grit is allowed to collect between the steel balls, and is prevented from getting between the bearing surfaces themselves and so grinding the bearings. This is, in my opinion, the principal advantage they have, and it is a great one. I venture to refer Mr. Chas. Hosken to the last paragraph printed above the correspondence column.—F. J. Garrard.

[56956.]—**Ball Bearings.**—Thanks to "Invicta" and C. Hosken for their replies on this subject; but I think that the latter is somewhat wide of the mark in comparing the bearings of a bicycle or tricycle with those of a steam-engine. In the one case you have steam as a great force, and in the other only the slight power exerted by a man's body, therefore requiring only a very small bearing surface. Now, I am going to state facts which C. Hosken cannot controvert as to this particular case, in which he says the friction of the ball bearings is shown. The tricycle was bought about two years since, and has been in constant use ever since; between 4,000 and 5,000 miles having been run. Now, I will make it as short as I can. The last few days before the discovery of the worn out balls, I noticed that it did not run quite so lightly as before, and thought I would take out the bearings and overhaul it generally. Now, the only place where I found any stiffness was in the box filled with the remnants of one crushed ball, and eleven others mixed with the bits, and grinding each other away. In the other boxes the balls were quite good, and needed nothing at all. It is rather puzzling why the broken one, being soft, should grind the others away, or why one should give way and no other. I can assure C. Hosken that directly I put new balls in the box the machine ran a deal lighter—in fact, just as it did at first, and as the total bearing surfaces do not measure more than about a square inch, I fail to see why the ball bearings are a mistake. It is an undisputed fact that machines, not steam-engines nor looms, but bicycles and tricycles, do run lighter with ball bearings, and if further proof is wanted take the balls out, and run the machine on the collars of the axle, and it will show itself soon. I, and more besides, would like to have this matter well ventilated, and there are plenty that can do it.—Secundus haud Ulli.

[56959.]—**Castings.**—If "Foundry" will use his sand as dry as possible, and dust his moulds very lightly with Morgan's plumbago, I do not think he will have to complain again of the small holes spoiling his castings, especially if he pours his metal very hot, and allows the moulds to cool before opening them.—Metal Moulder.

[56961.]—**Boating.**—I have not seen or heard of any invention of this kind; but the drawing is a rough sketch of a plan of my own that I thought of over five years ago. I feel confident it would answer your purpose. Fig. 1 is a plan of the parts when fixed together; *a* is a bevel wheel with a square hole part way through and a round one the rest of the way with a bolt at *f*, tapped into the round end and a guide for a brake at 1 (*a* can be made into two parts, as shown by the dotted lines in Fig. 2), *a* must be made in the square hole, so as to ride easily on the shaft *d d*. *b* is a bevel wheel made to be fixed on shaft *d*, as shown in Fig. 3; *a* and *b* wheels must be made both the same size and same number of teeth; *e* is the end of the shaft *d*, fitted so as to work into the round part of *a*, a groove cut lengthways and around, as shown at 3 3—that is, for throwing the machine into different gear when you want to go ahead or astern, the bevel wheel *a* must be in the position as shown in Fig. 1, but when you want to back water with one and pull with the other, by placing the bevel wheel *a* in the position as shown by the dotted lines in Fig. 1, Fig. 4 is the shaft for Fig. 2 to work on; Fig. 5 is the brake that fits on Fig. 2 at 1, so as you can move Fig. 2 with, so as to lock the shafts together, so as to enable you to work the paddles as you want to. C in Fig. 1 is a big bevel wheel with a handle on it to drive it with, or if that is not power enough, you may add more cog-wheels on to



c. A stand could be made so as the bearings will come where it is marked with crosses, and you could put a bearing on the gunwale of the boat. Fig. 6 is the end of shaft *d* at *e*, showing the groove at 3. I trust you can make this out, or someone else may improve upon it.—T. HUNDEL, 1, Milk-street, Frome.

[56967.]—**Deafness.**—The causes of deafness are various. If the drum of the ear is perforated, there is little, if any, hope of being able to hear again. This case of deafness, like numerous others, cannot be successfully treated apart from personal inspection of the ear by a good aural surgeon. Avoid quacks, as any particular disease of the ears demands skilful treatment, and should not be tampered with by non-medical persons. I am much inclined to think that your case is not one in which the drum is perforated, as you state that you can hear sometimes. When the drum of the ear is perforated no vibration of the surface of the drum can take place, and in the absence of vibration of this particular portion of the ear total deafness must in consequence follow. I have no faith in artificial drums, and believe them to be similar to most other things that are so extensively advertised; but I am not prepared to state that artificial drums are of no use, as I have never tried them, or yet ever intend to. I know of one case of deafness in which the patient was told that the ear was perforated, and was advised to have an artificial drum fitted. Fortunately for the patient, the advice was discarded, as the real cause was an accumulation of wax in the ear, which is a common cause of deafness. My opinion with regard to the case in question is that the deafness proceeds in consequence of a small tumour existing in the external ear—that is, outside the drum; but the treatment of it should be placed in the hands of a good aural surgeon. Deafness from the result of a cold proceeds in consequence of the Eustachian tubes being partly closed, which prevents the vibrations of certain portions of the internal ear, through deficiency or total loss of the necessary amount of air required.—G. FRYER.

[56968.]—**Chlorophyll.**—According to text-books on chemistry, this substance may be obtained by digesting green leaves for several days with ether, evaporating the filtered liquid to dryness, treating the residue with boiling alcohol, and adding to the solution a small quantity of milk of lime, which throws down the colouring matter. The precipitate is treated with hydrochloric acid and ether, whereupon the latter rises to the surface, and leaves chlorophyll on evaporation. Chlorophyll thus obtained is an earthy powder insoluble in water, and very stable. Mulder assigned to it the formula $C_9H_9NO_4$, and Morat thought $C_{18}H_{20}N_2O_5$ was better. According to Hoppe-Seyler its percentage composition is—carbon 73·74, hydrogen 9 72, oxygen 9·54, nitrogen 5·68, ash 1·72; and as neither Mulder nor Morat take into account the ash, their results are erroneous. It certainly contains iron, and plants deprived of iron become chlorotic, being unable to produce chlorophyll. According to Griffiths it is a compound of iron with some sort of a glucoside, possibly analogous to amygdalin, $C_{20}H_{27}NO_{11}$. Dr. A. Yschirch argues very strongly that pure chlorophyll has not yet been obtained, and that the stuffs got from leaves by such methods as given above are merely products of decomposition, more or less remote from true chlorophyll. I am inclined to agree with this view, for when we consider the marvellous power which green plants have of decomposing $CO_2$ under the action of light, a power possessed only by plants containing chlorophyll, we must, I think, come to the conclusion that the body which confers this power has a vastly more complex formula than any of those assigned to the so-called chlorophyll. It has never been formed artificially, and there is no chance of its synthesis, so long as its formula is nearly as great a mystery as that of protoplasm itself.—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56969.]—**Hydraulic Ram.**—You are correctly informed as to this. There are two valves, one opening into the air-chamber, the other controlling the waste water. There is nothing so abstruse about the question, as you will see. By a well-known law, the normal pressure multiplied by the speed gives the maximum pressure. Hence, though the pressure of the head of water itself would not support the escape valve of the ram, yet at each stroke the velocity of the flowing water, multiplied by the permanent head, is not only much more than sufficient to raise the valve, but is also able to on its closing to open the valve in the air-vessel. The hydraulic ram acts by momentum, and not by constant pressure. In your case, no doubt, the valve is made in itself heavy enough to more than balance the permanent head of water. No sooner is the force due to the momentum expended first in closing the waste-water valve, and forcing also into the air-vessel, than a recoil or rebound takes place also, so that the escape valve must fall owing to want of pressure behind it. The recoil is utilised and proven by the action of the snifting valve, allowing air to pass into the ram, as if a momentary entire absence of pressure did not take place, the valve could not open at all.—INVICTA.

[56969.]—**Hydraulic Ram.**—"Melting Mechanic" asks a very natural and intelligent question; but he would search in vain for a satisfactory reply to it in any English work which I have seen touching on this subject. It is, indeed, marvellous that so admirable a machine should have been so much neglected by our writers on hydraulics. Now, as to the cause of the fall of the outer valve, which puzzles "M. M.," as it has puzzled most people who have thought about it: clearly it is not the weight of the valve alone which brings it down—there must first be a removal of pressure from below it, and this is effected thus: At the moment when the outer valve closes there results an immense increase of pressure on the whole inner surface of the ram. This lifts the inner valve, and drives a quantity of water through it. When the force of the impact is spent, the inner valve descends again with a force due to the pressure of water in the delivery pipe above it. The inner valve thus becomes itself a kind of ram butting against the water in the motive column and giving it a backward motion, which it retains by reason of its inertia even after the inner valve has closed. At this critical period, which lasts only for a small fraction of a second, there is a removal of pressure from below the outer valve, enabling it to fall by its own weight; it not only falls by gravity, but is "sucked" down by means of the more or less, perfect vacuum beneath. The valve should have no more weight than is required for strength; of course, more water is sent up through the inner valve than returns. There can be little doubt that there is also an alternate expansion and contraction of the metal of the ram causing a recoil of the motive column, similar to that resulting from the descent of the inner valve. If a horizontal piece of brass tube be connected with an ordinary tap, and the open end of the tube be bent upwards and furnished with a little valve like the outer valve of a ram, the valve will begin to rise and fall alternately as soon as the tap is turned on, and will continue to pulsate as long as there is a flow; indeed, even without this contrivance, the recoil of the water may be both felt and heard at the tap itself if the pressure is sufficient and the tap admits of being closed smartly. The outer valve of a working ram will continue to rise and fall with the inner valve plugged and with no air-chamber. I must forbear to speak of the inner air-chamber, important as it is, further than to remark that its office is to supply air to the air ball, and to moderate the violence of the ram's action. It does not, on the whole, assist the fall of the outer valve, as one is sometimes told in books, and as I long supposed it did. On the contrary, the outer valve falls with more force and promptitude without it.—W. A. S.

[56972.]—**Watchwork.**—There is nothing which exemplifies the old adage "Practice makes perfect" better than polishing; indeed, it is only by constant practice that anyone can become a good polisher; but when once you get into it, it is quite simple. The steel must first be filed or turned quite square, and then hardened and tempered. It can now be polished with red stuff, either by rubbing on a bell-metal block (which has been filed and stoned quite true) with a circular motion by means of a pointer. I generally use a drill stock, or place the work on a piece of soft wood in the vice, and use a long bell-metal polisher. By far the best medium for giving the work a finish is diamantine, which must be used with a white metal polisher; but great care must be taken, as it polishes very quickly, and if used too quickly is apt to make the work look foxy. In all polishing it is very important to keep the work and polishers quite square and true. Great care must also be taken to keep the work, polishers, &c., quite clean; this is especially important in regard to diamantine, as the least atom of grit or dirt will quite spoil the finish. In the above I have supposed that "Escapement," as he is in the trade, is acquainted with the different tools, and the way to mix the polishing mediums, &c. The best way to clean the work is with soft bread.—C. A. W.

[56974.]—**Boiler.**—To "INVICTA."—Your boiler has, supposing the firebox to be from 12in. to 13in. diam., ample heating surface for driving an engine 2in. bore and 3½in. stroke, as long as the speed is moderate. The firebox is too low; with a 3ft. shell, it should have been not less than 18in. in height with a baffle plate; for the low-pressure steam it will generate it will steam fast enough. As to the working pressure, some careful experiments with copper generators recently have made me very careful; and in view that copper rapidly decreases in strength as the temperature rises, I should want a good factor of safety, and would, therefore, say 10lb. as the safe working pressure. I have perused the pages of this week's issue, but cannot find the description of dynamo you mention, so that I cannot give you an opinion; but it must be a very small dynamo that something less than the one-eighth of a horse-power would drive with much effect; therefore, unless the dynamo be a mere model, your engine will not drive it. I am assuming that with full steam you get 200 revolutions a minute from the engine, which I doubt, with a load. When the description in question appears, if it escapes my notice, remind me, and I will tell you what is then my opinion.—INVICTA.

[56977.]—**Load on Short Span.**—For the sake of the querist, will "Dubliniensis" show how the result 18·29 is arrived at? The moment of inertia of a square section being $\frac{1}{12} A d^2$, and of a circular section $\frac{1}{16} A d^2$ (A being sectional area, and $d$ the depth in each case), give a ratio of about 10 to 6 in the strength of the two sections of the same depth; then the strength of a square beam on its side and on its edge being in the ratio of 2 to $\sqrt{2}$, how is the result 20·21 arrived at?—J. S. C.

[56979.]—**Model Locomotive.**—(1) No; your boiler will not drive even one such cylinder properly. All the parts are too small; such a boiler would not supply even a single cylinder ½in. by 1in. properly. And one point is, that with a single 1in. flue you cannot deal with the heat necessary to make the firebox do its share. The boiler must be both larger and also designed in a technical way to work satisfactorily. I will help you in this, if you desire, with plans, but the present boiler will not do. Size of ports for cylinder ¾in. by 1¼in., stroke should be ⅜in. long by ⅛in. wide for steam, and ⅜in. by ¼in. exhaust. Bars $\frac{3}{16}$in. wide.—Invicta.

[56980.]—**Electrical.**—If the coil were fixed and the core free to move, on passing a current through the former the latter would be drawn into the coil, tending to embrace as many lines of force as possible; conversely, if the core is fixed and the coil movable, the latter will be drawn on to the core.—Fra. Broadbent, Hammersmith.

[56983.]—**Window Glass.**—A piece of ordinary looking-glass is fitted into a frame of angle zinc or copper, with a back of the same metal, a brass socket made of a piece of tube and provided with a set screw being soldered to the centre of the back in a horizontal position. Another socket, also having a set screw, is fixed on the frame or wall outside the window in a vertical position. A piece of brass rod about 12in. long is bent at a right angle 2in. from one end; the short arm of this is fitted into the wall socket, and the end of the long arm is passed through the socket on the back of the frame. The glass can thus be freely swung both horizontally and vertically, and can be clamped in any required position by means of the set screws.—R. T. Lewis.

[56984.]—**Legal.**—You run a very great risk, and would have some trouble to convince a magistrate that you gave the ale away. He would, in all probability, say you were evading the law.—C. D. R.

[56987.]—**Volvox Globator.**—May be kept alive if placed in any fresh-water aquarium and supplied with pond or rain water. Of course, fission takes place. To mount whole ring a cell with an ebonite ring fastened down to the glass slip with Canada balsam. When dry, fill the cell with a mixture of equal bulks of methylated spirits, water, and glycerine. Take up a little of the fluid containing the volvoci, drop it into the mixed solution, which at once kills and preserves them, slide over a thin cover glass, wipe the edge with blotting paper, run a circle of good gold size round the edge of the cover glass, which circle repeat every three days for a fortnight.—S. Bottone.

[56987.]—**Volvox Globator.**—(1) I know of no good means of keeping them long alive. They are usually accompanied by small crustaceans—Cyclops especially—which feed on them. (2) They may, I am told, be dried on a slide, heated, stained by gently pouring stain on them, so as not to displace them, and mounted in balsam. (3) A volvox is a green globe, freely swimming and rolling in the water, and of about the size of the dot of an i, or rather larger. When fully grown it is hollow inside. On examination with a power of 25 or so, a volvox is seen to be generally of a light green, studded with dots of an intenser green, and these dots are nucleated cells lying beneath a transparent layer which is visible round the edge, and is thicker in the younger and smaller specimens. In the younger specimens the cells are massed together; they recede from each other with growth, leaving, however, lines of connection between them, which may be seen by a somewhat higher power, aided by a condenser or the use of oblique light. Most of these cells remain single cells, and from the nucleus of each, or of very many, proceeds a split flagellum, and the sphere is rolled through the water by the united action of these. At the edge the nuclei may be seen to be pear-shaped, the stalk of the pear being the flagellum or undulating thread; in the middle or in front view they look circular, or almost so. In other cells, however, the nucleus divides and subdivides, and round each subdivision of it a cell-wall is formed, so that instead of a single cell we have several closely aggregated together. The aggregation contracts at the edge, and becomes saucer-shaped instead of plate like; the rim of the saucer clinging to the inner side of the hollow sphere, which the original volvox is. By a continuation of the same process, the saucer becomes a cup, and the cup a sphere, and this new sphere is a young volvox, which presently becomes detached, swims about in the central cavity of its parent, and may there attain a considerable size. About fifteen months ago I mounted about a dozen slides of volvoxes, which now seem to me to be as good as when they were first put up, though I suppose they must have deteriorated somewhat. First, I took them up from the water in which they were swimming, and put them into cells made on slides with gold size some time previously. This I did with a glass tube drawn to a point, taking off the superfluous water till I had enough volvoxes. Cells made with rings of metallic zinc would have been better. Then I drained off as much of the water as possible with a tube, and by the same means introduced a 1 per cent. solution of osmic acid, which I allowed to remain for a few minutes, till they just began to change colour, when the osmic acid was in turn drained off, and they were treated to several changes of distilled water, to the last of which some drops of an alcoholic solution of iodine aniline green were added. This was then washed out with Haentsche's fluid, coloured red with magenta, and, the red fluid being removed, they were mounted in plain, uncoloured Haentsche's fluid. The result is a double stain, which is distinctive, but not very effective; but the flagella, the nuclei, and the lines between the cells are as visible as I remember them ever to have been. The Haentsche's fluid, as directed by Haentsche, is three parts alcohol, two water, and one glycerine; but these proportions are not intended to be superstitiously adhered to. I was sparing with the alcohol, and finally used perhaps 50 per cent. or more of glycerine, gradually increasing it in the various washings. My mistake was to use two shallow cells, in consequence of which many of the larger volvoxes have burst, or ruptured from the pressure of the covers; but, except for the tear at one side, they are perfect volvoxes. I am not sure that these torn volvoxes are an unmitigated evil, for they have discharged the young ones in their interior, which can be seen more clearly.—Francis Grant.

[56988.]—**Siphon.**—When the siphon is simply put with the shortest of its legs in the liquid, the atmospheric pressure is exerted equally inside it, the siphon being now filled with air. When it is filled with water and replaced, the column in the longest leg runs out; this causes a vacuum which draws up some more liquid through the shorter leg, and this process is continued till the whole of the liquid has run through the siphon. If you don't fill it with water, but suck the air through the longest leg, a vacuum is produced, and, once started, the process goes on as before. The longer the long end of the siphon is, the faster the water goes through, for the simple reason that the long end being lower, the difference between the height of the surface of water and the bottom of the longest leg is increased, and therefore the pressure is greater.—R. A. R. Bennett.

[56988.]—**Siphon.**—To "Invicta" and others.—When you place the short leg of the empty siphon in the tank, did you give the following question a thought—viz., why should the water rise in the empty siphon tube, and then run down the longer leg? Is there any natural or other law, except that of capillary attraction, that would cause water to spontaneously rise above its own level? If our friend will consider a moment, the action of a siphon is exceedingly simple, as is caused thus: The column of water or fluid in the long leg, obedient to the laws of gravity, would, on the exit being opened, at once descend. In thus descending, a partial vacuum would result in the bend of the siphon; but the atmosphere, pressing on the surface of the liquid, instantly forces fluid into what otherwise would be a partial vacuum, and thus a constant descending flow of water is produced until the fluid sinks below the end of the short leg of the siphon. Air then passes in to fill the space left void by the water, and the action of the instrument naturally ceases, because an equilibrium is set up. Therefore, unless you fill the siphon first, where is the column of fluid to fall by gravity, and thus set up a siphon action? By the same train of reasoning, the longer the length of the long leg of the siphon, the greater the speed of the flow would be, because the length of the descending column is longer. In practice, there are many other considerations, such as pipe friction, for instance; but, in theory, the longer the pipe in vertical height, the greater should be the speed of flow, and, therefore, the volume delivered in a given space of time.—Invicta.

[56988 (**Siphon**) and 56892 (**Hydraulic Ram**).]—The information asked for can be found in any elementary book on hydraulics.—J. S. C.

[56990.]—**Bell Telephone Circuit.**—I do not understand your question. Express yourself more precisely, and I will assist if I can.—S. Bottone.

[56991.]—**Blowhole.**—It must depend on the locality of the hole. But, in any case, my advice would be, if it be at all possible, to drill out the speck, and screw in a small pin of either iron or brass as tightly as possible, and file off to the surrounding surface.—Invicta.

[56992.]—**Hydraulic Ram.**—I do not know in what direction you want the information, or I would with pleasure give it. Something is stated on the subject on page 418 even. A ram with a fall of 9ft. should be able to deliver water into a tank 80ft. above it readily enough.—Invicta.

[56995.]—**Fixing Boiler.**—There are two plans almost equally good. If room is not an object I should fix it in brickwork similar to the regular egg-ended boilers, the furnace being underneath the front end; but the minimum space I could advise would be 4ft. 6in. in length × 3ft. 6in., that being the floor area. If that be too much room then you may put the boiler on end, in which case it would stand in a total space of 3ft. 6in. each way; but that system would render it almost imperative to have a mud catcher fitted inside. In view of this I should myself prefer the fixing horizontally. Let the flue be then a simple flash flue from the bridge to the end of boiler, and thence by a square section flue to chimney. Carry water level at the 15th inch from the bottom, and bring flue up to the 12th inch only on each side. I should myself run with, say, 30lb., not more, unless I saw or knew the boiler to be safe for more. It should be safe at 60lb., at least, supposing all was right; but as it is best to err on the side of safety, and not having seen the boiler, I would say 30lb., and be safe; but an hydraulic test to, say, 75lb. would be better—Invicta.

[56997.]—**Hydropathy.**—I have derived great benefit from the "tub and sponge," but with the addition of Tidman's sea salt; and I knew of a very severe case of nervous depression cured by means of the "pack" used twice a week. To learn how to do the pack properly, "Quixote" should visit a hydropathic establishment for a few days—not one of the flirting and match-making description, but one like Smedley's at Malvern, where hydropathy is really practised.—B.Sc., Plymouth.

[56997.] — **Hydropathy.** — I am afraid "Quixote" will not receive much benefit from above practised at home. The great point is change of air, scenery, society, and a carefully regulated diet. There are numerous hydropathic establishments in all parts of England and Scotland. "Quixote" should enter one of them, if possible, for as long a term as he can spare; even a short stay will do him more good than he will ever receive from medicine: at least such is my experience. I took gallons of medicine prescribed by eminent doctors (I am not exaggerating in the least) without benefit; in fact I got steadily worse, until I got into a very weak, nervous state; life was a burden. This was about forty years ago. I then went to a hydropathic establishment, learned to live properly, went through the regular treatment, which at that time was strict, both diet and treatment, and have lived comfortably till well turned the allotted span of life. I may add that it can scarcely be called a "cold water cure" now, as hot water, Turkish baths, &c., are much used in the present treatment. I would strongly urge "Quixote," or anyone labouring under nervous disease, indigestion, &c., to go and do likewise.—W. Grimshaw.

[56999.]—**Question in Algebra.**—The twelve soldiers can be arranged in line in $\underline{|12}$ different ways, and so can the twelve sailors. We have, therefore $(\underline{|12})^2$, different ways of arranging the men in two lines, one containing all the sailors, and the other all the soldiers. We can now break up our line of soldiers into three sections of four men each, and we have 13 different positions among the sailors (namely, between any two or at either end), from which we must choose three in which to place our three sections of soldiers. This can be done in $\frac{13 \times 12 \times 11}{\underline{|3}}$ ways, and remembering that the sections must not change their positions with regard to one another, we see that there are

$$\frac{(\underline{|12})^2 \times \underline{|13}}{\underline{|3} \times \underline{|10}}$$

different arrangements satisfying the conditions

$$\text{or} \quad \frac{13 \times (\underline{|12})^3}{\underline{|10} \times \underline{|3}}$$

—C. Planck.

[57000.]—**Spark Coil.**—Fasten a piece of stout copper wire into a wooden handle and cross it in the flame of a gas or spirit lamp. The projecting end will serve as an excellent soldering tool for all kinds of small work. You must tin the wire first, of course, and use resin as a flux.—C. D. R.

[57000.]—**Spark Coil.**—The tinfoil of condensers is usually placed between boards, which are a size smaller than the foil-plates. One inch or so of each alternate plate consequently projects over the sides of the board. Press the edges together and bend them over on the board, fastening them down to it by small binding-screws. Connect the condenser by short lengths of wire from the screws, soldering the connection of the lengths to the wires which come from the pillar and the spring. If the point of contact is thoroughly clean, the touch of a bolt should do no harm.—Bobadil.

[57000.]—**Spark Coil.**—If you trace the connections underneath you will find that one main wire goes to the spring of the contact breaker and another main wire to the contact breaker pillar or that part which carries the adjustable screw. The condenser, you will find, is made of tinfoil insulated. All the plates of foil coming out on the one side must be connected together, and by the aid of a piece of insulated wire with the spring of the contact breaker, whilst the other series of foils must be similarly connected to the contact breaker pillar. The main wires I refer to will also not be fine silk-covered wires such as you describe, but should be wires, say, at least No. 18 wire gauge.—Invicta.

[57001.]—**Carbon.**—A battery cell made as described would answer your purpose for a bell, if sufficiently large; but you would obtain better results by using two plates of carbon with one of zinc between them, and sal-ammoniac instead of common salt. If charged with a solution of bichromate of potash in sulphuric acid and water, it would work a coil.—R. T. Lewis.

[57001.]—**Carbon.**—If sufficiently large enough it will give a current sufficient to ring a bell, but only for a short space of time, as polarisation almost immediately would ensue. You can obtain a better result by increasing the carbon surface six or eight times that of the zinc, but even then the cell is of no practical use, as the Leclanché is far superior in every way. For coils and motors the cell is of no use however.—C. D. R.

[57005.]—**New Steam Motor.**—To "Invicta."—The motor in question being a patented machine, I am sorry that I cannot myself assist Mr. Miles. But, as in the case of another querist, I have written the manufacturers, asking them to communicate with you. In another case they have granted him a free special license to make one engine only, and I understand it is in hand already. I have no doubt that my request to them in like manner would procure you satisfactory terms to make one engine for own use only. I cannot say how far such special license will be granted, but so far they have been issued as a personal favour to me and to readers of the "E. M." only, so that any one else interested may most likely be dealt with in the same way if they express their desires through the medium of this journal. My own personal influence would certainly be employed in their favour in that case.—Invicta.

[57008.]—**Granule Battery.**—I should not recommend "W. Y. K." to use a granule battery, as I tried one myself made up of six quart cells, and could not light one 5-c.p. lamp properly. Also there is a very unpleasant smell with it, and it is very troublesome to recharge.—W.

[57008.]—**Granule Battery.**—It is quite possible to make a 6-cell granule battery in the way you propose, but it is not advisable; they always leak, and are very awkward to recharge. Marine glue can be purchased at most shops; it is made by dissolving one part of indiarubber in 12 of benzine, to which is added 20 parts of lac; it should be applied hot with a brush. The E.M.F. of an ordinary granule is about 1·60. You can use outer cells made of any waterproof substance; large jam jars or glasses will do equally well. It is impossible to say whether the size you mention will give the current required without measuring; you must find this out for yourself. If you do not pack the granules tightly round the electrode the resistance will be very large. The granule cell has been very much overrated. You must, therefore, be prepared to be disappointed if you expect too much from it.—C. D. R.

[57010.]—**Swan's Studio Plates.**—Mr. Chapman's assistant was quite right; these plates, if properly treated and duly exposed, will yield good pictures with any known developer. "N." must be wrong in his work.—S. Bottone.

[57010.]—**Swan's Studio Plates.**—"N." had better write to Messrs. Mawson and Swan for a small book entitled "Photography," price 3d., which gives directions for working their plates. I may say that they recommend Edwards's developer as well as their own.—A. R. F.

[57010.]—**Swan's Studio Plates.**—Chapman's assistant was quite right in saying that any developer will do; and if "N." has tried four, the difficulty lies in a wrong exposure or access of light to the plate. Swan's developer is: No. 1 Solution, 30 grains pyro, 10oz. water; No. 2 Solution, 1 drachm liquor ammoniæ, 1 drachm bromide of ammonium, 10oz. water. Use these solutions in equal proportions. For an amateur, the standard developer of the New York Photographic Society is better, although it is very slow, and the developing dish should be kept covered as much as possible. It is as follows:—For a ¼-plate, water 2oz., dry pyro 4 grains, carb. soda 11 grains, sulphite soda 22 grains, carb. potash 11 grains, yellow prussiate potash 11 grains.—B.Sc., Plymouth.

[57013.]—**Boiler.**—To "Invicta."—In comparing the two boilers, one 32in. long by 13in. diam., and with dished or egg ends, and the multitubular boiler, 20in. long by 11in. diam., and with five 1in. tubes from end to end, I may tell you that the available heating surface is practically the same in both; but looking at the matter all round, I should prefer the 32in. boiler to the tubular one, as a large portion of the latter would not be as effective as that of the former; whilst the tube ends would be likely to give trouble some day, besides acting on the speed of the draught. The externally-fired boiler also would hold steam better from the larger bulk of water, and the water level would not be subject to the same rapid variations; therefore, stick to your first boiler.—Invicta.

[57014.]—**Watch Jobbing.**—I am puzzled to know what "Lever" really does want. The most generally useful tool for watch jobbing and making is a good Swiss mandrel; cost about £7. But for turning in balance staffs, pinions, cylinders, &c., he must use the ordinary turns, cost about 10s., and require a lot of practice.—Escapement.

[57015.]—**Steam Canoe.**—This is decidedly a case where the paddle engine could better be utilised than the screw, as the narrowness of beam needs all the additional stability that can be imparted. The boiler should certainly be horizontal, to keep the centre of gravity low; whilst a small paddle-engine would take the minimum volume of steam. Had our friend given me the depth of his canoe, I could have better dealt with the question for him. Neither has he told us the length of stroke of his 2in. cylinder. I am also writing him direct to oblige me with sketch of his canoe—firstly, because I want to see the general design, and also that I might better advise him as to the engine and boiler. If the opinions I form would interest the readers of the "E. M.," I shall be happy to express them.—Invicta.

# UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

**Transmission of Power.**—The following particulars of the cost of transmitting power by the Daft system are given in a pamphlet issued by the Safety Electric Power Company of New York, which possesses territorial rights acquired from the Daft Company. The nominal radius covered is 2¼ miles. Engines, boilers, foundations, &c.; eight dynamos, aggregating 500 horse-power; line receivers, switches, &c., total £17,100. Running expenses per diem: Rent, coal, engineers, linemen, two firemen, station dynamo men, outside receiver men, 10 per cent. depreciation, oil, waste &c., total per diem, £19. It is assumed that 350 horse-power will be ready for delivery at any moment, and following the ordinary practice of power producers, at least 600 horse-power can be rented therefrom to small consumers, limiting the delivery to, say, 10 horse-power for any one consumer; in this way an average of £30 per horse-power per annum may be realised in New York City, which would therefore return after deducting running expenses, a net income of £11,000, or 65 per cent. per annum on prime cost. The estimate of running expenses is probably excessive, since 365 days of working expenses have been provided for, whereas this would in practice probably be reduced to 313 days, thus reducing the expenses and increasing the earnings. The plant for a ten-mile section of street-car lines, on the assumption that fifty cars are to be run and that 150 horse-power is ready for delivery on the track at all times is 62,000 dollars. Fifty loaded cars may be moving at the same time. Assuming a run of sixteen hours per day per car, the expenses are put at 49 dollars, or less than a dollar per car, whereas the care and maintenance of 400 horses cost 286·687 dollars per day, or more than 5 dollars per car.

# QUERIES.

[57022.]—**Galvanic Batteries.**—To "Sigma."—I have just purchased a copy of your work on "Electricity," and am reading it with the greatest interest and pleasure. Would you kindly give me some information on the following point? I understand that the current in a galvanic battery is due to the difference between the energy, which is generated (by chemical action) at one plate, and that which is expended (by producing chemical decomposition) at the other plate. Thus, in the Daniell battery, sulphate of zinc is formed in one cell, and sulphate of copper is decomposed in the other; but the energy of the combination of the acid with the zinc is greater than that of the acid with the copper; the force generated in one cell is greater than the force expended in the other cell, and hence there is a current, equal to the difference (minus resistances) of the energies, flowing from the zinc to the copper. But there is a battery of German origin, lately invented, in which the fluid is chloride of iron solution, and the elements iron and carbon. The chloride is decomposed, its chlorine forming fresh chloride with the iron plate, and its iron being reduced at the carbon plate. Now I want to know what is the source of the current in this battery; where does the energy come from which is transmuted by the battery into electricity?—for the force expended in pulling asunder the chlorine and the iron must be exactly equal to the force generated by their union; the energy developed at one plate is absorbed at the other, and the result ought to be nothing. The forces being equal and opposite, the equation might be thus put: $x - x = 0$, but there is a current. I understand that the reduced iron is oxidised by the action of the air, and falls to the bottom as oxide. Can it be that it is this oxidation which is the source of the current? If so, then it seems to me that the current ought to flow the wrong way, that is, from the carbon to the iron. Would you kindly explain the action of this battery, especially with reference to the principle of the conservation of energy?—Ex-Garrison Gunner.

[57023.]—**Second and Fourth West India Regiments. Colonial Police Forces, &c.**—Will any of your numerous readers inform me as to the qualifications necessary for entry into the Second and Fourth West India regiments, more especially the last named? I find no mention of the Fourth in an old Army List in my possession, but a gentleman lately returned from South America, assures me that there is such a regiment, and that he has heard that entry is not difficult, but is unable to give particulars. I should also much like to know something of the police forces in our newly formed colonies—Guiana for instance—and whether it is possible to get an appointment in one of them, and the *modus operandi*. I have served for six years in South Africa, throughout the Galeka, Gaika, Basuto, and Zulu Campaigns, and am anxious to get military or colonial police work again, if possible. The fullest information will oblige.—Morosi.

[57024.]—**Dead Centre.**—Could any correspondent inform me of the cause of the difficulty I experience in my launch engine to get over the dead centre? The slide valve, in the opinion of two engineers, is set right.—Amateur.

[57025.]—**Midland Scotch Express.**—Can any of your readers inform me what was the number of the engine which took this train, on Thursday, July 9, between London and Leicester, when the driver was killed by coming in contact with a bridge whilst mounted on the tender?—Bogie.

[57026.]—**Problem.**—Can any kind reader work the following, algebraically?—I cannot get an elimination between the three unknown quantities. A man has whisky worth 16s. a gallon, and another lot worth 19s. a gallon. How must he mix these with water to make a mixture of 51 gallons worth 12s. a gallon?—Bogie.

[57027.]—**Pure Phosphorus.**—Will Mr. Alfred H. Allen kindly give me a simple method of preparing absolutely pure unoxidised phosphorus? I am informed that when taken internally in this form it has proved very beneficial in nervous exhaustion, and being a sufferer, I am anxious to prove the truth of the statement.—Phos.

[57028.]—**Stamping in Relief.**—Can you kindly give me the process of above suitable for thin brass patent tickets, and the probable cost of the needed appliances? I am having a good deal of annoyance and delay getting my tickets, and think I could turn them out to better advantage myself.—Stamper.

[57029.]—**Turbine.**—What power can I get out of a 2in jet of water under a pressure of 15ft. by means of a turbine? Also oblige by giving directions how to make a turbine? What number of revolutions per minute would it run at?—Highlander.

[57030.]—**Galvanising Clout Nails.**—Could any one inform me how to galvanise ordinary clout nails? Also the pickle required for cleaning them, previous to dipping in the bath of melted zinc?—Nails.

[57031.]—**Soap Analysis.**—Will any of your readers kindly inform me how to estimate the percentage of alkali (soda) in soaps, also fat and water?—Y. C.

[57032.]—**Clock Making.**—I intend making clock from instructions given in "E.M.," Vol. XXXI., and wish to know the most suitable lathe to get for the job; perhaps someone will advise—Nomen.

[57033.]—**Refining Gold.**—Would any fellow reader who is up in chemistry kindly inform me how I may separate the copper and silver from nine carat gold, so as to form chloride of gold? Also how to recover the silver as well? Any information will be thankfully received.—Alloy.

[57034.]—**Painting Iron Bath.**—I shall feel obliged for instructions how to prepare paint and apply it to a cast-iron bath, so that it will stand hot water?—D. B. and S.

[57035.]—**Bicycle Spring.**—I wish to make a spring somewhat after the Arab style. Will "Invicta," or others tell me the sort of steel rod to use—will Bessemer do? Ought it to be bent cold, or at a dull red heat

Does it require hardening and tempering to a blue? The rod will be about ¼in. diameter.—E. O. B.

[57036.]—**Bicycle Painting.**—Which is best to clean grease off from spokes, &c., preparatory to painting, benzoline or solution of caustic potash in water?—E. O. B.

[57037.]—**Sewing-Machine Work.**—I shall be glad to be informed if and how the stitching is marked out in ladies' garments—corsets for instance? I want a quantity of sewing done very evenly.—J. W.

[57038.]—**Wimshurst Influence Machine.**—Will Mr. Wimshurst kindly inform me whether it is possible to construct a multiplate machine on his principle, and if so, would he give me, through the medium of your Reply Column, full details relating to the construction of such a machine with twelve pairs of plates?—Aurora.

[57039.]—**Firing Mines.**—Wanted to know simplest plan of firing charges of gunpowder, 100yds distance, by electricity; have a ½in. coil, and what form of battery to use for constancy? To be fired about three times daily.—Mikado.

[57040.]—**Voltaic.**—I want to make some simple electric motor which, actuated by a small galvanic battery, would show a school boy the effect of motion produced by a voltaic cell. How can I manage this?—Pith Ball.

[57041.]—**Battery.**—What is the reason opticians sell us those small cells for bell and coil work? Those cell require acids powerful in proportion to their smallness to work them. Will it not answer to use much larger cells, requiring for the development of electricity diluted acid, thus reducing the working cost. Where the size of the battery is no objection, is not there a decided gain in large carbons, and zinc actuated with weak acid? Is there not a mania amongst our opticians and electrical engineers, for making those small batteries?—E. B. Fennessy.

[57042.]—**Spark Coil.**—Would some good friend favour me with a list of experiments, which I may perform with a coil—something else than showing the spark through vacuum tubes, and giving shocks?—E. B. F.

[57043.]—**Spectroscope.**—My spectroscope shows the D line as a thick line, having two conspicuous but much thinner lines close to it on the red side of the spectrum; the instrument has five prisms. Should it show the thickest of those three lines double, or does the sodium line, the D line, actually consist of two fine lines, and one coarse line?—Jolly Miller on the D.

[57044.]—**Silver-Plating.**—I have just commenced silver-plating, and like other amateurs, have met with a difficulty. I have been successful with brass and copper, but I cannot succeed with German silver. I get a good coating of silver on the metal, but as soon as I put on the scratch brush, it peels off. I have made a solution of cyanide of mercury, but I don't know the correct way to use it, and should it be used for all articles? I have used a battery of carbon and zinc, placed in a large glass for holding 1qt., and I have also tried the same with copper and zinc, using in both cases, oil of vitriol and water as chemicals: they both act very well, but which is really best for the purpose? I shall be thankful for a little information respecting the above, or any hints on the subject.—A Beginner.

[57045.]—**L. and N.W. Compounds.**—Will "Meteor" or any other reader, kindly give a full list of numbers and names of above locos.—Cotswold.

[57046.]—**L. and N.W. Manchester Express.**—What class of engine is new working the 12 noon from Euston to Rugby?—Cotswold.

[57047.]—**G.W.R. Goods Engines.**—Can any correspondent give principal dimensions and weight of 2321 class?—Cotswold.

[57048.]—**Hardening Dividers.**—Would any kind reader inform me how to harden a pair of dividers? I have tried several times, but cannot harden them properly. I have hardened them in oil, but they either snap or bend, and will not go back.—E. B. W.

[57049.]—**Dynamo.**—I beg to thank Mr. Bottone for suggesting cog armature 4in. long, in reply to my query 56909. Before proceeding, however, I desire to state that the malleable field magnets are arranged on a frame, so that they will all bolt to one side of the pole-pieces; therefore I would further ask if the embracing pole-pieces being consequently 4in. wide, would be magnetised throughout their widths, considering the F.M.'s are only about 4½in. long on the space for winding between their faces, and being arranged in circular form, the pole-pieces will, I anticipate, be evenly magnetised in their radii; but perhaps you will consider a narrower ring of greater diameter will suit better now that I explain the F.M.'s will only operate on one side of the pole-pieces only, being arranged on a circular frame like the Siemens alternate machine. What should be the neutral space between these poles?—Subscriber from No. 1.

[57050.]—**Dynamo Construction.**—To W. H. Graves.—Will you kindly give dimension of armature for dynamo, to give about 15 amperes at 50 volts., together with a description of field magets and winding? I require it to be shunt wound. Also give description of field magnets for the armature you described lately in "E.M.," which I have nearly completed.—Electra.

[57051.]—**Legal.**—I am married, but no family; I have made a will, and bequeath all and every my real and personal estate and effects, unto my wife, absolutely. After this will is made, I buy a freehold land and house, and in the deed I find this clause:—"And the said E. Pelham doth hereby declare that he was married since the first day of January, 1834, and that no woman who shall become his widow shall be entitled to dower out of, or in the said land, messuage, and hereditaments." Will this clause prevent my wife having this freehold at my death?—E. Pelham.

[57052.]—**Weight and Stress of Beam.**—Would any reader work out the following for me?—A beam of any material, say (fir, Riga) supported at both ends, 10ft. long, 7in. deep, 2in. thick. Find the weight, and prove that stress is proportional to strain.—R. B.

[57053.]—**Coil Connections.**—Will any of our electrical correspondents assist one of their struggling friends in the following?—1. How must I connect the wires from a medical coil, with only one kind of wire used? 2. How must I connect the wires from a medical coil, with primary and secondary wires used? 3. How must I connect the wires from a 1in. spark induction coil, with condenser, dischargers, and commutator of the cylindrical shape? A sketch would greatly assist.—Weekly Subscriber.

[57054.]—**Cleaning Stationary Engine.**—To "Invicta."—A friend of mine who is in charge of a stationary or land boiler of the Robey principle, is much perplexed about the cleaning of it, as the only water obtainable contains a great quantity of lime, and the tubes being placed zigzag, it is almost impossible to dislodge the deposit. Perhaps your extensive experience would enable you to suggest something which would soften the deposit, and render its removal possible without drawing the tubes. I may mention that a great force of water cannot be obtained to wash out with.—Apprentice.

[57055.]—**Electric Bells in Series.**—There always has been a difficulty in working three or four bells in series, from one battery; this appears at last to be overcome, judging from the following:—"The short-circuiting device was in use for series working the bells some years; but it is now abandoned for the far more satisfactory double-wound electro-magnet. By the new arrangement the resistance of a bell is greatly reduced when striking the gong, and as all the bells are independent of one another, they offer less resistance, and take less cells." A description of the double-wound electro-magnet used in the above, will much oblige.—M. S. E.

[57056.]—**Problem.**—Will one of our readers kindly inform me how to ascertain which is the greater number, those that have died since the time of Adam, or those that are alive at the present time, as we all know that the population of the earth is always on the increase, and that more are born than what dies? Some persons contend that the number of living exceed the number of the dead, but as more are born than what dies, in a stated time, the greater number seems in favour of those living. If any of "ours" will kindly state how to solve this problem, I shall be exceedingly obliged, as others contend that the number of the dead exceed that of the living by 50 per cent., but no proof of this statement seems to be possible to obtain. Will any reader throw some light on the subject?—G. Fryer.

[57057.]—**Transmission of Power by Belts.**—Would some of your numerous readers kindly give some easy method, or formula, of measuring the above, in the case of belts transmitting small powers? I have tried several formulæ, but without success.—H. L. C.

[57058.]—**Science Examination, May '85. Mathematics, Stage II.**—Would any of your numerous correspondents kindly give a solution of the following? "Two circles touch each other externally at C; show how to draw a straight line through C to meet the circumferences at A and B respectively, so that AB may equal a given straight line, less the sum of the diameters of the circles?"—A Student.

[57059.]—**Power.**—Kindly tell me what power, in foot-pounds, would it take to carry a weight up stairs at an angle of 60deg., 110lb. 22ft., and what it would take to lift same by chain pulleys, which are as 1 to 24?—Hydrathana.

[57060.]—**Theoretical Mechanics.**—Will some reader kindly inform me whether a knowledge of the Calculus is absolutely necessary in order to enable one to acquire sufficient knowledge to pass in Honours in theoretical mechanics at the May exams.? If so, what work would be suitable for the purpose?—G. H.

[57061.]—**Platinotype Process.**—Will any reader of "Ours," who has tried the above process, give me his opinion as to whether it is easier or cheaper than the ordinary toning process for prints? It looks very simple and easy when one sees it done at the Inventories; but I should like to know if it answers well in the hands of an amateur, before I get a license from the company, which I am very much inclined to do.—R. A. R. Bennett.

[57062.]—**Automatic Musical Instruments.**—Will someone kindly tell me whether the aurephone is made on the lever principle like the organina, or simply suction through valves of paper like the orguinette? If one makes a continuous band of music, is it possible to repeat one tune any number of times, as the separate verses of a hymn?—R. A. R. Bennett.

[57063.]—**Specific Heat.**—If 5grm. of snow at 0deg. Cent. be mixed with 25grm. of water at 30deg. Cent., I want to find the temperature of the mixture?—Edmond Murray.

[57064.]—**Bisulphide of Silver.**—Will Percy W. Stanley (reply 56584) kindly give more particulars about Roseleur's bisulphate of silver method of silvering? I should much like to try it. Also, if it will require varnishing over on a barometer dial?—Argent.

[57065.]—**Cork-cutting Machine.**—Will some of our kind friends give me a sketch of a cork-cutting machine, to cut a cork from ⅝in. to 1½in. in one cut, and the largest size to be cut with the same machine is 2¼in. and the smallest size is ¾in.?—X. Y. Z.

[57066.]—**Reducing the Amount of Lime in Chalk Water.**—There is a process, I am told, for doing this. Clarke's patent is being used in some places, and I wish to know where I can learn what the Clarke's patent process is? I have been told it is mixing a certain small weighed portion of quicklime with so many gallons of the water; the hydrate of lime enters into chemical combination with the lime already in the water, forming an insoluble salt of lime; the result being that when the sediment has deposited, the clear water is left with a much less percentage of lime in solution than before. It will be a great boon if any of your readers can inform an old subscriber to Mechanic of this process.—C. H. D.

[57067.]—**Mineralogy.**—As I am spending three months in the heart of the mining districts of the Oural, am anxious to make a collection of stones. Unfortunately, my knowledge of mineralogy is very limited indeed. Will some of your readers, who understand this subject, have the kindness to inform me what stones it is best to collect, how to judge good specimens, and if a good collection has any value in England? As specimens are easy to be obtained, I wish to take this opportunity of making a collection, which, if I do not keep myself, can give to my friends who care to have them.—Oural.

[57068.]—**Dynamo.**—To W. H. Eaves, Coventry.—Having nearly completed an armature (exactly two-thirds less in all its details, with the exception of thickness of the sheet-iron discs) from the admirable description and sketch given by you in letter No. 24267, May 22, will you kindly inform me in regard to the following points? 1st, What size wire (and approximate quantity) will be best to wind the said armature with, which I intend for lighting purposes? 2nd, What number of 20-c.p. lamps may I reasonably expect from such a machine, granting the machine to be fairly well made from an electrical point of view? 3rd, If not too impertinent for me to inquire, when may we expect your promised letter, giving particulars in regard to winding field magnets, &c., and supposing when it appears (as I hope it will soon), in order to save further troubling you, if I make everything exactly two-thirds less in all its dimensions, what size and quantity of wire I will require for field magnets, &c.?—Cymro Gwledig.

[57069.]—**Hot Water.**—I have a hot-water arrangement that does not answer unless the fire is constantly attended to. The boiler, a copper one, is 9in. by 9in. by 4½in., is set up in a 16in. sham register grate, and is 17in. below the hot-water cylinder, which is 21in. by 11in., total length of flow and return pipe 82ft., which is ½in. lead, 7lb. to yard, it supplies five toilet cocks, the first one being 21ft. and the last one 41ft. from the cylinder. It supplies also, when necessary, about 50ft. of 1in. wrought-iron piping for heating purposes. My requirements are from one gill to a pint of very hot water about every three minutes from any of the cocks. Would a larger cylinder make the difference, or would the addition of another boiler, heated by gas and placed 3ft. from the first cock, and so arranged as to work jointly or separately? If so, a sketch would oblige.—Les Doents.

[57070.]—**Telephone.**—Having completed a pair of telephone (bells) I find that they will not speak at all. The magnets are 4in. by ⅜in., and each has a ½in. bobbin, wound with ten layers of No. 40 covered wire, the diaphragms, 2¼in. diameter, I adjusted to about a 1-30th of an inch from the magnets in each case, and can get no result at all. I sent a current from a small bichromate cell through about 1,000ft. of covered wire, and inserted the telephones in the circuit, one at each end of the wire, and when the circuit was completed, I could distinctly hear a click in both, at a distance of about 5in. from the phones. Are my magnets strong enough?—they each can lift about ⅞oz. If not, could I make them stronger by sending a current from a battery round the bars? Also have I got too much wire on the bobbins?—if so, how many feet ought I put on each bobbin of No. 40 wire, as it is difficult to tell by ounces how much of each wire to wind on, each number being thicker or thinner than the other, as I suppose would make a great deal of difference in strengthening or weakening the induced current, the same as it does with the inductoin coil, according to the wire used. Would Mr. Bottone or Mr. Lancaster, kindly put me to rights in this matter, as I should to have a pair of these instruments to talk with, merely for an experiment than anything else.—Telephonic.

[57071.]—**Beat Valves in Hydraulic Rams.**—I should like to supplement the inquiry of "A Melting Mechanic," and ask what rules govern the weight of the beat valves in hydraulic rams, and how the best weight is calculated when the height of fall and diameter of inlet pipe are known. What would be the weight for inlet pipes 1in., 1½in., and 2in. diameter? Also, how is the size of the inlet pipe calculated? What system do the makers go upon, and what proportion should the delivery pipe bear to the inlet pipe? What are the reasons why hydraulic rams are not in favour among engineers, and what are the chief sources of failure? What governs the length of inlet pipe—*i.e.*, what proportion should the length of the inlet pipe bear to the fall? Any further information on the subject will be very acceptable.—R.

**Cement for Marble, &c.**—Stir to a thick batter with silicate of soda, twelve parts Portland cement, six parts slaked lime, six parts fine lead, one part infusorial earth. Very excellent for marble and alabaster. The cemented object need not be heated. After twenty-four hours the fracture is firm, and the place can with difficulty be found.

**Every Workman** connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

**Holloway's Pills.**—Indigestion, flatulence, and cramps.—These stomachic Pills are invaluable for all complaints of this character. They also correct the liver, and give tone to the whole alimentary canal. They purify the blood, correct all vitiated secretions, and elevate the tone of the nervous system when it is depressed.

## ANSWERS TO CORRESPONDENTS.

⁂ *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

### HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

**The following are the initials, &c., of letters to hand up to Wednesday evening, July 15th, and unacknowledged elsewhere :—**

Rev. A. Willan.—C. P. Krauth, jr.—Chas. J. Simmons.—F. Hotham.—J. Epps and Co.—T. Fletcher.—Vacuum Brake Co.—G. Pardoe.—John Browning.—S. Beeching.—Lancaster and Son.—Gaseous.—Geo. Cordon.—An Anxious One.—A Working Man.—Mine Agent.—Wheels.—Brother Pivot.—Cambrian.—Accumulator.—Eyepiece.—C. A. W.—W. B.—Glatton.—F. H. Wenham.—J. C. L.—J. H.—Bobadil.

J. O. Evans. (We do not know that anyone is prepared to fit up the apparatus necessary; but there is much about the system in recent numbers.)—W. Ouin. (Receipt implied by the statement that it would be noticed. See p. 420.)—Robt. H. Hibbert. (We really do not know. Look in the files of the engineering papers. 2. No doubt there are both photographs and engravings of Hawarden Castle and Hughenden Manor, and an advertisement in the Wanted Column would probably bring you several offers. 3. If you mean directions for making a camera, they have been given several times—see, for instance, pp. 212, 380, 474, Vol. XXXVII.) — Architectus. (The question was answered, as well, perhaps, as it can be, in No. 1,009, p. 472, under the heading of Flies or Midges. It is stated that the Japanese lily (L. auratum), when it is in flower, will keep flies out of a room.)—Arnold T. Reed. (See answer to "Watchmaker" last week. If you want more mathematics than Guthrie uses, you should try Clerk-Maxwell's and Sir W. Thomson's works. In preparing for South Kensington examinations it is always advisable to join a class, as teachers know, as a rule, the most suitable books.)—Electron. (They nearly all depend upon making a bit of platinum wire red hot by its resistance to the passage of the current. Consequently, any cell which has a high electro-motive force, if only for a minute or so, is better suited to the purpose than a constant battery. 2. See recent back numbers and the indices generally.)—A. B. C. (See p. 61, No. 1,017, p. 592, No. 1,014, and the indices.)—R. S. Trews. (We do not think it is fully explained in any one number, though there is much about it in many.)—A Constant Reader. (Your six questions have nearly all been explained in recent numbers. The second is not explicit. Do you want to turn the rods hollow?)—H. W. B. (Most likely chloride of zinc; but see indices.)—J. Cox. (Apparently only a case of long sight complicated in some way that an oculist could not determine without personally examining the eyes.)—Highlander. (It depends on what you mean by practical. You should read up the numerous articles which have appeared in this paper. Dickson's "Practical Organ Building," Crosby Lockwood and Co., will perhaps suit you.)—Walter Griffiths. (The diving bell used at the late Polytechnic was, of course, supplied with a set of air-pumps, and air was pumped into the bell as soon as its mouth was sealed by the water.) — Ninnim. (Sperm thinned with a little paraffin oil is as good as anything in the shape of oil; but for some purposes plumbago mixed with purified fat or glycerine gives excellent results.)—Skinner. (Why not examine a specimen? If we recollect, it twines with the sun—that is in the direction of the hands of a watch.)—A Young Youngster. (Phosphorus is usually sold in the form of sticks kept in water or naphtha. What you appear to want is luminous paint. 2. We suppose you mean a picture of a colt foal; but whatever you mean the question is of no interest, and is on a par with the "dead donkey.")—J. Trutman. (The pamphlet is published by the U. S. Department of Agriculture, Washington, D.C. We do not know how it is to be obtained except on application to the department.)—A. B. C. (We cannot undertake the responsibility of defining what is and what is not an infringement of a patent; nor can we supply numbers and prices of specifications unless we happen to know them. Patent agents will supply the desired information for a small fee, and the specifications can be readily obtained from the Sale Office, Cursitor-street, Chancery-lane, W.C., by means of post-office orders, &c., addressed to H. Reader Lack.)—Patent Office. (The Patent Office is situate in Southampton-buildings, Chancery-lane, at No. 25, we believe; but if you address your communications to the Comptroller, Patent Office, London, they will be delivered as certainly as if you put the full address.)—Roland Oldham. (B. is right. So long as there is sufficient depth to kick out in, mere bulk of water under the swimmer makes no difference. The denser the water the easier the swimmer supports himself in it.)—Velocity Ratio. (We think you can obtain the examination papers from Chapman and Hall, 11, Henrietta-street, Covent-garden, W.C.)—J. Wilson. (A mixture of finely-powdered plumbago and washed fat, such as hog's lard, will, if wiped on in the thinnest possible film, preserve the iron for a long time if not handled.)—A. R. F. (Water gas is usually understood to mean the gas obtained by passing steam over or through incandescent coke. See recent numbers and the indices.)—Celt. (We do not see how anyone can give a satisfactory answer to such a question without knowing more about your method; but if you are quite sure that you have discovered a means of using packing for engines which makes it last five times as long as by the ordinary methods, it would certainly be worth while to take out letters patent.)—W. D. H. (Answered many times. Rub the article over with soap or wax, scratch through with a needle, and apply nitric acid in the lines. The rules are engraved by proper dividing tools.)—Engineer. (Why not join the classes in your city? A resident of Glasgow should have no difficulty in obtaining education, and you have at least one or two libraries. Read Rankine's and Fairbairn's works, and enter yourself at Anderson's College.)—New Subscriber. (The father is powerless, and must, moreover, support his daughter. His only remedy is by an action against her seducer for damages for the loss of her services. This is the present disgraceful state of the law which has been so severely commented on lately by the Archbishop of Canterbury and others.)—Dubliniensis. (Reply by all means, and demonstrate the error in Molesworth.)—Bernard O'Reilly. (Why should they not emigrate? With their united capital and disposition to work hard, they should do well either in Canada, New Zealand, or the United States.)—Turner and Fitter. (The best month to arrive there is October. If Scotch, go to Dunedin; if English, to Lyttelton or Auckland. Go by sailing vessel. Clothes required much the same as at home, and tools the same. A little stock of preserved meats, jams, cocoa, &c., to supplement the rations aboard ship, is advisable.)—W. C. (Yes.)—R. S. Nolan. (You are too good for this world, that is all! A six-foot graduate of a University "philosophical, mathematical, determined, stern," with a father with large influence with M.P.'s and others, who condescends to inform an editor that he desires employment of a gentlemanly nature where no "cringing" or "asking favour" is expected, must surely be joking.)

## CHESS.

All Communications for this department must be addressed to J. Pierce, Langley House, Dorking.

### NOTICES TO CORRESPONDENTS.

Correct solutions to 945 by A. A: E. Lecluse, (a most visible key move, otherwise meritorious), and T. L. Robins.

To 946 by R. A. Bennett (difficult; variation of B-Q 2 very good) F. A. Vincent, E. Stanley Follwell (but main play not given!) V. S. Pochin, B. Fison (a very fine and difficult problem), G. T. Stringfellow, A. S. Olver, and H. Culmer.

To 947 by E. S., H. Culmer, A. S. Olver, Streetgate, J. A. Miles (an excellent problem).

N. and F.—Your solution of 946 breaks down if

1 ———
P moves

L. S. Chivers.—If your solution is intended for that of 945, you had better look at it again.

A. S. Olver.—Thanks for the problem, which is interesting. You are right as to the number of solutions in 945. The solution to which you refer was incomplete.

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

## USEFUL AND SCIENTIFIC NOTES.

**Alkali, &c., Works Regulation Act.**—The Chief Inspector, Mr. A. E. Fletcher, has issued by the Local Government Board his report of the proceedings under the Act during the year 1884. The growth of the department may be judged by the fact that 20 years ago the report then issued dealt with the inspection of 85 alkali works. The number of works now registered under the Act of 1881 is 1,041, and the number of manufacturing operations is 1,420, two or more being in some cases under one certificate of registration. This great increase is due partly to the development of the chemical trades, but mainly to the taking in of several branches of chemical manufactures by the Act of 1881. When Mr. A. E. Fletcher took up, in 1884, the work of his predecessor, Dr. Angus Smith, he carried out the latter's intentions by rearranging the districts, so that there are now seven districts where there were five. These districts are more compact than before, and thus much time is saved that was spent in travelling under the old arrangement. These districts are (1) Scotland and Ireland with 144 and 50 works respectively; (2) Newcastle or the Northern district with 86 works; (3) St. Helen's, consisting of Cheshire, North Wales, and part of Lancashire, 161 works; (4) Manchester, consisting of East Lancashire and Yorkshire, 158 works; (5) Birmingham or South Midland, 112; (6) Bristol or South-West, 125; and (7) London or South-East with 205 registered works under inspection. There are in all nine inspectors. Scotland and Ireland have each an inspector, and each of the other districts one. There is besides an additional inspector appointed for Widnes. The 1,041 registered works—this number is an advance of 51 on that of 1883—are classified as follows:—Alkali, 127; sulphuric acid, 153; chemical manure, 222; gas liquor, 16; nitric acid, 69; sulphate and muriate of ammonia, 247; chlorine, 3; salt, 111; and cement, 93. Only one prosecution took place under the Act during the year. To the general report are appended elaborate local reports from each inspector, containing tables dealing with the statistics of every single work in the several districts.

Of the forty-six students from the City of London College, prepared by Mr. Henry Adams, M.I.C.E., F.S.I., examined in Building Construction by the Science and Art Department last May, only one failed. Over ninety-four per cent. of the students from this college during the last twelve years have been successful.

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words .. .. .. .. .. .. .. | 2 | 6 |
| Every additional eight words .. .. .. .. | 0 | 6 |

Front Page Advertisements Five Shillings for the first 40 words, afterwards 9d. per line. Paragraph advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

|---|---|---|
| Twenty-four words .. .. .. .. .. .. | 0 | 3 |
| For every succeeding Eight Words .. .. .. | 0 | 3 |

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. | d. |
|---|---|---|
| Sixteen words .. .. .. .. .. .. .. | 0 | 6 |
| For every succeeding Eight words .. .. .. | 0 | 6 |

⁂ It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday, to insure insertion in the following Friday's number.

## TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve months, Post Free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII., XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., and XL., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words, and 3d. for every succeeding 8 words.*

Offer **Gold Watch**, Self-inking Printing Press, Electrical Apparatus and cash, for about whole-plate Tourist Camera; Lenses wanted.—Beds, Belbroughton, Stourbridge.

## THE SIXPENNY SALE COLUMN.

*Advertisements are inserted in this column at the rate of 6d. for the first 16 words, and 6d. for every succeeding 8 words.*

**Motor Castings**, materials for Electric Bells, Batteries, Galvanometers, Intensity Coils, Microphones.—King, Mendham, and Co., Bristol.

**Insulated Wire Table**, showing size, weight, resistance per foot, feet per ohm, &c., price 3d.—King, Mendham, and Co., Bristol.

**Standard Ohm**, in box, copper poles, guaranteed correct to ten thousandth of ohm, 21s.—King, Mendham, and Co., Bristol.

**Wimshurst Influence Machine**.—Sole Manufacturers of Improved Pattern. Numerous testimonials as to thorough efficiency.—King, Mendham, and Co., Bristol.

**Galvanometer Cards**, improved for tangent and ordinary combined, 2½in., 8d.; 4in., 10d.; 6in., 1s.; post free.—As above.

Write for **King, Mendham, and Co.'s** large new and reduced Price List, post free 4 stamps.

**Trouser Lengths**, 5s. each. Cheap Cloth for Ladies' Dresses, Mantles, Boys' Suits.—Hewitt, 27, Winfield Mount, Leeds. Patterns free.

**Electric Depot**, 10, Deansgate, Manchester.—Electric Breast Pins, 25s. Electric Bells, 4s. Induction Coils, 8s.—Millar, Proprietor.

**Chemical Apparatus**. — Catalogue, 90pp., 500 illustrations, posted 2d.—W. Hume, Lothian street, Edinburgh.

**Photographic Apparatus and Chemicals** for professionals and amateurs. See new illustrated catalogue, post free.—Hume, Lothian street, Edinburgh.

**Mica**, otherwise Talc.—RICHARD BAKER & CO., 9, Mincing-lane, London.

New Illustrated Price List of **Screws, Bolts, and** Nuts for Model Work, drawn to actual size, sent on receipt of stamp.—Morris Cohen, 132, Kirkgate, Leeds.

**Oxygen Gas**, compressed in cylinders, handiest and safest for limelight.—Clarkson, Compressed Gas Chemist, Bartlett's-buildings, E.C.

**Oxygen Gas**, compressed into iron bottles, liquid nitrous oxide and carbonic acid.—Clarkson, Compressed Gas Chemist.

**Oxygen Gas**, compressed into iron bottles: prices on application.—Clarkson, 28, Bartlett's-buildings, Holborn, E.C.

Astronomical **Telescopes** of all kinds and Apparatus or Fittings made by A. Clarkson, 28, Bartlett's-buildings.

**Eyepieces**.—Huyghenian of any power to fit any telescope, 15s. each. Sun Diagonals, £1. Star Diagonals, 30s.

Astronomical **Telescopes**, second-hand, by best makers.—Clarkson, 28, Bartlett's-buildings, Holborn, E.C.

**Stammering Cured by Correspondence**.—"Practical Guide," and 600 Cases, 1s. 4d. Books of testimony (1s., or returned).—N. H. Mason (B 40), 18, Stavordale-road, Highbury, London.

"**Warne's Sheet Metal Worker**" to be sold, cheap, covers soiled.—94, St. Augustine's-road, Camden-square.

**Piles**.—Worst cases cured first application. Indian Ointment, sent 13 stamps.—Thomas Palmer, St. Helen's, Auckland, Durham.

**Harness Oil**, or for Caps of Wheels, 3s. 6d. per gallon.—Pinnel Brothers, 214, Whitechapel-road, London.

**Model Steam Engines**, made or repaired, separate parts fitted up, boilers made to order; sets of castings of every description.—Lucas and Davies, 21, Charles-street, Hatton Garden, London.

**Bamboo Fishing Rods**, 10 or 6-joint, 1s., 15 feet; 5-joint, 9½d., carriage 3d.—Bristow and Co., Hull.

**Gas Engine**, bargain, 1-man, off Dorrington's castings, built for exhibition, no further use for it, cylinder, 4¼ dia.—Wm. Ainsworth, *Gazette* Office, Accrington.

**Tic**. This excruciating agony completely cured by Thomas Palmer's new remedy, and health and strength restored, 13 stamps.—St. Helen's, Auckland, Durham.

**Swan Holders**, 5s. dozen. Switches, Machines, Lamps, at large discounts.—Nicholson, 5, Rumford-place, Liverpool.

**Piano-Making**. — Instruments supplied at trade prices. Photo. and List post free. Also Piano Fittings.—W. G. Whittingham's Piano Factory, North-street, Clapham, London, S.W.

**Do we get Heat from the Sun?** No! Every one interested in science should read this little work. By R. Humphreys. Post free, 1½ stamps.—11, Cambria-street, Fulham, S.W.

**Batteries** (to the trade). — Pint Bunsens, Daniells, Bichromates. Other sizes in proportion. List free.—Below.

Small **Electro-Motors**, 14s., 24s., 78s. per dozen.—J. Hanks and Son, Seaforth, Liverpool.

**Oils**.—Lard and Olive Oils (substitute for). Reliable information. Stamp for reply.—J. M., 6, Hamlet-street, Bootle, Liverpool.

**Inventions Exhibition**.—Hot-Air Engines, small size, for driving models in shop windows, or for driving sewing machine or light lathes, price £9.—Britannia.

**Hot-Air Engines**, larger size, suitable for 4ft. lathe, £27.

These are both **Heated by Gas**. That at £9 cost about 1½d. per day. A lady can manage it. No risk, no noise.—Britannia.

**Prize Medals**.—We have obtained Six Prize Medals for Lathes and Tools.—Britannia Co., Colchester.

**Lathes**.—Nearly 200 varieties. Hundreds of Parts rough or finished. Catalogue, 6d.—Britannia.

**Old Scientific Instruments**, Broken Model Engines, &c. For estimate of cost for repairing, relacquering, &c., send particulars to H. F. Lovegrove, Optical Works, Slough, who makes this class of work a speciality.

**Piles cured at once** by using Dr. Farquharson's Remedy, free by post for 2s.—2, Standish-street, Burnley.

**Model Engine Castings**.—Makers of Model Engines should send for a Set of Hughes' Iron Castings. Best and softest metal. Lowest prices in the trade.

**Horizontal Engine**, 1¼in. bore, 2½in. stroke, 5s.; 1½in. bore, 2in. stroke, 5s. Working Drawings, 1s.

Double Cylinder **Horizontal Engine**, 1½in. bore, 2in. stroke, 10s. Double Cylinder Vertical, 7s. Working Drawings, 1s. 6d.

Vertical **Launch Engine**, 1in. bore, 1¼in. stroke, 3s., post free. Double Cylinder, 5s. Working Drawings, 1s. 6d.

Half horse-power **Vertical or Horizontal**. Working Drawings, 2s. Three-quarter horse double-cylinder Horizontal, 17s. 6d.

Send for **Catalogue**, 2d. Six Lithographed Designs, 3d.—Hughes, Mersey Dockyard, 17, Smith-street, Kirkdale, Liverpool.

**Fishing Bait**.—"Red Ching."—This celebrated Chinese bait received first prize in Fisheries Exhibition. Will keep for years. Salt and fresh water fish attracted from a far distance in large numbers by its peculiar odour and colour, take the bait voraciously. One packet will take bushels of fish.—Post paid, 1s. 2d.—Agent, Dr. Evans, Importer, Shirley, Southampton.

**Vermilion**, best, 2s. 4d. lb.—PINNELL BROTHERS, 214, Whitechapel-road, London, E.

**Gas Engine Oil** (best), 2s. 6d. gallon.—Pinnell Brothers, 214, Whitechapel road.

**Lathes. Lathes**. Cheap and good. Satisfaction guaranteed. List two stamps. Best make.—Robinson, Catherine-street, Sheffield.

**Gas Engine**, two-man, cost £35; lowest price, £16. In good working order.—Box 27, Northallerton.

Le Merveilleux ½-plate **Camera, Lens**, and Tripod, complete, 14s.—James McNab, junior, Deloraine-place, Renton, Scotland.

Powerful **Electric Motor**, will drive two sewing machines, 30s. Offers.—E. Wagstaff, 6, Hale-street, Islington, London.

**Novelty Makers and Others**.—If you have something new which will bear advertising, submit samples between 6 and 8 p.m., to Haydon and Co., 123, Strand, London, W.C.

**Drawings of Slotting Machine**, or **Machine** Hammer, 2s. Oxford Frame Machine, or Electric Machine, 5s.—Edward Dale, C.E., Sherborne, Dorset.

**Working Drawings of Hydraulic Rams**, post free, two shillings.—Edward Dale, C.E., Sherborne, Dorset.

**The Art of Palmistry**.—A Chart with full particulars, 7d.—H. Dyke, 21, North-street, Taunton.

**Fretwork**.—Catalogue of every requisite, with illustrations, free for 6 stamps.—Harger Bros., Settle, Yorks.

Half-horse **Engine**, brass cylinder, governor balls and valve complete, splendid model, 35s.—W. Harding, Butter-market-street, Warrington.

Pair of Irish's **Acoustic Telephones**, second-hand, in good condition, 30s.—As above.

One Fletcher's two-oven **Gas Ranges**, with three radial burners on top, £2.—As above.

**Marvels**.—Double Opera and Field Glasses, from 5s. 6d. Lists, with engravings, free—J. B. Dancer's Depot, Hamstead-road, Handsworth, Birmingham.

**A Treatise** on the Manufacture and Medical Value of Koumiss, 12 stamps.—M. Lawrence, 63, Aitkenhead-road, Glasgow.

Blue-Black, Jet-Black, Waterproof **Inks**, Fruit-Salt, Pain Killer, Hop Bitters. Recipe 7d. Three 1s. 6d.—Stanley, Manchester-road, Poplar.

**New Time**.—Alter your Clocks and Watches. Twelve Sets of figures, with instructions, 6d.—Wheeler, Preston.

**Water Motors**, for sewing machines, organettes, window advertisements, 32s., 42s. List one stamp.—Wheeler.

**Fan Castings**.—Improved Registered Designs; 4in., 3s.; 6in., 4s.; 8in., 5s. Drawings, 4d.—Wheeler, Engineer.

**Water Motors**.—Complete one horse-power, £. Half, £6; Quarter, £4; Eighth, £3.—Thomas Wheeler, Preston.

**Coca Leaves**.—The best, safest, and cheapest stimulant. Consignment of choice quality just received.—Marks and Co.

**Coca**.—Certain cure for indigestion. Best stimulant in exhaustive mental or physical work.—See "Medical Weekly Review."

**Coca**.—Best antidote for inebriety. See "Family Doctor, No. 17. By their use hunger is averted, and fatigue unknown.

**Coca Leaves**.—The Bolivian Consul writes:—"Their stimulating powers are marvellous. The Indians never travel without them."

**Coca**.—Sample packet, with medical and scientific opinions. 12 stamps.—Marks and Co., 17, Newcastle-street, Farringdon-street, E.C.

**Model Engine Castings**, best and cheapest. Send list (stamp) and compare.—Wood, Dalley-street, Broughton, Manchester.

3in. **Bench Lathe**, chucks, cost £4, new; offers.—T. Gratwick, 160a, Wick road, South Hackney.

Tudsbury and Sons' Improved "High-tension" **Wimshurst Machine**, with their new Compound Ebonite Plates.—Edwinstowe, Newark.

Steel **Name Stamps**, 3d. per letter. Figures (set) 2s. 4d. Letters, 6s. 4d. per post.—E. F. Baldwin, Robins hill, Gloucester.

4in. screw-cutting **Gap Lathe**, new and complete, £12.—A. Halls, Howard-street, Yarmouth.

To be sold (through death) a case of **Drawing Instruments**, used once; cost 13 guineas.—Mrs. N. Cassy, Bedford House, Gravesend.

Two H.-P. Launch **Tubular Boiler**, with or without Engine.—J. Reside, Brighouse.

One H.-P. **Launch Engine**; one H.-P. Engine and Boiler Combined, second-hand; very compact.—Particulars, J. Reside, Brighouse.

A 7½in. **Woodturning Lathe**, with 1¼ hole through the spindle, and a number of Chucks.—Reside, Brighouse.

**Lathe Carriers** various sizes, and two Hand Drills.—For illustration, apply J. Reside, Brighouse.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
*FRIDAY, JULY* 24, 1885.

## GAS ENGINES.*

THE author thinks it strange that an industrial machine having so widespread an application as the gas-engine should have "no literature," by which phrase he means that hitherto no work has been issued in this country devoted solely to the consideration of gas-engines, for there is much literature on the subject to be found in various periodicals, in Transactions of societies, and even in books. The gas-engine has, however, taken so prominent a place in the industrial world, especially amongst small power-users, that there are many who will gladly welcome Mr. Macgregor's work, although it does not profess to be exhaustive, and will not convey much information to those who are acquainted with the German treatises on the subject, and familar with the theories of thermo-dynamics. Mr. Macgregor avoids all references to the cycles of Carnot, for he considers that in practice the gas-engine has no affinity with them, and is not at present worth studying as a theoretical heat-engine. In the chapters devoted to the theory of the gas-engine he has consequently confined himself to deductions made from the experiments of the best authorities. Starting with the definition of a gas-engine, which will be objected to by hypercritics—for the author speaks of heat generated by the "combustion" of illuminating or similar gas, whereas it is really that rapid kind of combustion which is termed explosion—Mr. Macgregor points out that the first cannon might have been called the first gas-engine. The Abbé Hautefeuille, in 1678, invented a powder machine for raising water, and Huyghens, seven years later, improved on that, for he employed a cylinder and piston; but John Barber, in 1791, was really the first to take out a patent for the production of force by the combustion of hydrocarbons in air. F. Lebon, in 1801, constructed a furnace for making gas, which gas, mixed with air, he compressed into a recipient and presumably exploded the mixture with an electric spark, as he recommends an electric machine; but in those days new inventions were not taken up by syndicates, and there were few papers in which descriptions of new inventions were given, so that the records in the Patent Office are the only evidence available, and they are not always trustworthy, for a specification was often drawn so as to conceal the real method adopted by the patentee. It may, however, be accepted as true that the gas-engine on paper is at least as old as the century, and certainly Cheverton, who wrote in 1826, had the gift of foresight, for he pointed out that the practical mechanic wanted a dynamic engine, which is always ready for work without costing too much to drive, and causing no loss of time in preparation; and he went so far as to say that the advantages which society would derive from such a machine would be incalculable, even if the cost should be greater than that of steam. To the Frenchman, Lenoir, is due the honour of starting the gas-engine on its road to success, for he did produce a practical motor, which subsequently fell into disrepute because it was unable to substantiate the claims made for it. Hugon and Reithmann claimed the invention, but although the dates are only a quarter of a century old, there is much uncertainty about the matter. Like all new inventions, many of the experiments were carried out in secret, and it is most likely that several inventors had been endeavouring to carry out the same principle in a different manner. However, Lenoir made a gas-engine that would work, albeit rather expensively, and in 1867 Otto and Langen exhibited their engine, which is practically the forerunner of all successful applications of gas as a motive power, for it combined a knowledge of the theoretical requirements with considerable mechanical skill, and in a very few years a large number of their engines were sold. The start thus gained has never been lost, and the success which attended the earlier efforts of the firm established at Deutz enabled them to proceed with the development of the gas-engine, and the result is well known so far. Of late years, many improvements have been introduced, and the Inventions Exhibition shows, if any evidence is needed, that the gas-engine is the motor of the future, at all events where small power is required—say up to forty horses. The Otto and Langen engine of 1867 was, however, anything but satisfactory, for it made a fearful noise, and, like the earlier steam-engines, obtained its power from the atmospheric pressure on the piston—that is, the piston had a rod with a rack, which, when the explosion took place, was jerked upwards, and a partial vacuum being created in the cylinder, the piston was forced downwards, the rack, by means of ingenious clutch gear, imparting motion to the shaft. The Italians, Barsanti and Matteucci, seem to have been earlier by ten years than Otto and Langen in devising a practical gas-motor; but for some reason they did not persevere, and Gilles, of Cologne, having succeeded in making a comparatively noiseless engine, Otto was put on his mettle, and produced his well-known "silent" motor. An historical résumé of the invention of the gas-engine appeared in Vols. XXVI. and XXVII., based on the records of the Patent Office, and although Mr. Macgregor seems to have omitted a reference to the gas-engine invented by Mr. F. H. Wenham in 1864, it is on record in Vol. XXVII., p. 63, that Wenham "brought out in an almost perfect form the double-piston atmospheric gas-engine"—in fact, he has the honour of being the first to bring out an economically-working gas motor. Others may have introduced practical gas-engines, but Wenham's was an economical as well as practical success. Of late years the gas-engine has made great strides towards perfection, and except that in a work dealing with the gas-engine it is necessary to trace its historical development, the detailed descriptions of the earlier models are of little interest. Otto's engine is the typical gas motor, and is that one which has been the subject of the greater number of experiments. Mr. Macgregor gives a number of these in detail, including those of Messrs. Brooks and Steward, which we described in Vol. XXXVIII. p. 527. These gave the indicated work as 18 per cent. of the total heat of combustion of the gas, and the useful work as 14½ per cent. The experiments of Brooks and Steward were carried out under the direction of Prof. Thurston, with the view of checking his own results obtained from engines of various size and different design. Prof. Thurston found that a horse-power was obtained from 21 to 23 cubic feet per hour of water gas, the quantity used increasing slightly in the smaller engines. Messrs. Brooks and Steward found that 21 cubic feet of average good quality coal-gas might be accepted as the datum for calculations; but it is obvious that the quantity of air will depend on the quality of the gas, and to obtain the best results it is always advisable to ascertain the average composition of the gas used. Brooks and Steward found the ratio of air to gas to be about 7 to 1 when the Otto with which they experimented was running most economically; but they used a poor quality (Hoboken) gas, and probably a safe datum is from 7 to 10 volumes of air to one of gas, according to the quality of the latter. Crossley's improvements in the Otto are not changes in principle; but they have had the effect of increasing the efficiency and steadiness of the motor, and of remedying some mechanical defects. Mr. Macgregor mentions the various patents which have been taken out from time to time; but devotes more space to such designs as the Lenoir, Bischopp, Wittig and Hee, Körting-Lieckfield, Simon, Maxim, Siemens, Clerk, and Otto. Of Atkinson's designs he says, all present "novelties of ignition, regulation, and distribution, that we regret it is beyond the scope of this work to consider." Other well-known designs seem to have been dismissed in as few words, and of Siemens' latest we are told that "it is more notable for its theoretically perfect plan than for any practical results that have as yet been attained by it. It is very simple, and should be productive of highly efficient results; but it is observable that the highest results have not always followed the best theoretical design, particularly in gas-engines." Dugald Clerk's engine is described at some length, and a chapter is devoted to Clerk's theory, as set forth by that inventor in his well-known paper. Mr. Macgregor also devotes a chapter to the views of M. Witz, and another to the researches of Berthelot and Vielle, as given in the *Comptes Rendus*, on the relative speed of combustion in gaseous explosive mixtures. The chapter on the theory of the gas-engine, in which the method of calculating the heat evolved by the combination of the hydrogen and carbon of the gas with the oxygen of the air is set out, will be useful to many. The calculations, according to Mr. Macgregor, are more readily effected in the decimal system; but he afterwards gives reduction factors, where necessary, to "convert the results into the irrational system still in use by English engineers." The next sentence reads, "Taking 100 litres as the volume of gas employed, we find the weights in grains," which we take to be a typographical error, as the heading in the tables reads "Grms. per 100 Litres." As the work is, we presume, intended for English engineers, it would perhaps have been better if the author had adopted their "irrational system" throughout, for it is, to say the least, rather confusing to have litres and "heat in water-gramme degrees" in one chapter, and "cubic feet," "foot-pounds," and "heat-units per cent." in another. The chapter on the indicator diagram of the gas-engine will be useful to a good many who are studying these motors, provided they understand the formulæ, which are those of Profs. Ayrton and Perry. The work is illustrated by seven plates, containing altogether seventy-five figures, the engines selected being shown mostly in sectional drawings, with detailed sketches of parts, and as the text is divided into chapters on (1) direct-working engines without compression, (2) engines working with compression, and (3) compression engines with compression pump, the practical man will be able to readily obtain a good idea of the different types of gas-engines, and of the principles on which they are constructed.

## BELTS v. ROPES.

THE contradictory statements made in reference to the relative advantages of belts and ropes might with advantage form the subject of an inquiry by the Institution of Mechanical Engineers. A series of properly conducted experiments carried out by experts ought to be, and would be, of great interest to engineers and to power users, for as matters stand opinions are, to say the least, divided, though possibly the majority favour the belting. Even in connection with belting there is considerable difference of opinion as to the truth of the saying "nothing like leather," for while some declare for the comparatively new link belting as the greatest improvement in modern times, others will have nothing but cotton belting, or the patent beltings made up of plies of different materials. Those interested in the matter have a good opportunity of seeing the various kinds applied to all sorts of machines at the Inventions, and in spite of what has been said about ropes, two of the large engines have them, while in some cases they are employed in driving dynamos. There are certain conditions in which ropes are specially indicated, as, for instance, in driving from one pulley to several floors; but where the ropes all drive on to the same shaft, that is on one pair of pulleys, it is contended that they never pull all together as one: each rope has its own travelling speed, and consequently there must be a loss of power as compared with abelt. Ropes are, however, less costly than main belts—whether they are really cheaper is the point to be decided, and that can be satisfactorily done only by first determining the actual work of which ropes are capable as compared with belts; and then ascertaining their average life under different conditions, and the cost of replacing, in the shape of time required, when worn out, and also time occupied in tightening up, &c. These latter items could be easily found by users amongst themselves in the course of a few years; but we want first some authoritative figures made with the aid of the dynamometer in a series of experiments. Makers of leather belts are, as a matter of course, advocates of their own goods, but they not unfrequently state their case with fairness when reading a paper before a society. At the convention of the National Association of Millers, held a short time ago in Glasgow, Mr. John Tullis, of that city, read a paper on "Belts v. Ropes," in which he endeavoured to settle the question by reviewing the relative advantages and disadvantages of the two systems. Both have their admirers and advocates, and both, in Mr. Tullis's opinion, have proved worthy of much patronage. First cost is not everything, and though there is no doubt that main belts are more expensive than ropes, it is necessary, also, to take into account the extra cost of the grooved as compared with plain belt pulleys. Well-made, properly-stretched leather belts will run for 30 years, says Mr. Tullis, and will be good then for cutting up into smaller sizes. Belts and ropes both drive well, when the distances between the centres of the pulleys are great, and the pulleys themselves of large diameter, but ropes are beaten, Mr. Tullis thinks, when the shafts are near each other and the pulleys are less than 54in. in diameter. There are one or two exhibits at the Inventions which might cause him to modify that opinion, though, in the cases meant, it is true that the ropes are not employed for transmitting much power. Mr. Tullis's remarks on the treatment of belts are so good that we quote them almost *in extenso*, with the remark that many power users prefer to employ castor oil in preference to dubbin and boiled linseed oil. Mr. Tullis says:—After having been taken up once or twice during the first year, good belts require very little attention during subsequent years. If the belt is driving in a warm engine room it ought to get a coating of curriers' dubbin three times a year. All belts having much work to do ought to present a clammy face to the pulley, and this condition can be best maintained by applying one coating of dubbin and three coatings of boiled linseed oil during a year. This oil oxidises, and the gummy surface formed gives the belt a smooth, elastic driving face. A belt looked after in this way will always run slack, and the tear and wear will be inconsiderable. On the other hand, dry belts have to be kept tighter, because they slip and refuse to lift the work. The friction of the running pulley "burns the life" out of the belt while this slipping is going on. The driving face is made as hard as millboard, and as well polished as a millstone. Bushes are ground down, shafting worn, oil consumed, the belts killed and condemned, because the disease has been misunderstood. If a belt is wanted to do more work than was originally intended, by, say, an addition to the machinery of the mill, a very good plan of getting power is to run a second belt upon the top of the one in use. Do not connect them in any way, and the outside belt will work for itself, and do a large proportion of the driving. By way of experiment, I have made four 6-in. single belts, running independently on the top of one another over 4-ft. driver and driven pulleys, transmit over 80-horse power, the belts travelling at a speed of 1,800ft. per minute. Each of these belts did its own share of the work, and while running over its own circumference each gained a little over 30ft. per minute upon the one below; so that the outside belt travelled over 90ft. per minute more than the inside belt. The best leather for making belting is that known as "Orange Tan." This leather is made from the heaviest and best-grown Highland ox hides. During the process of tanning, instead of swelling, as is the case with all bark tannages, this leather becomes thinner in substance, and weighs 45 per cent. less than if tanned with oak bark. The breaking strain, according to Lloyd's Proving House test, is 45 per cent. greater than oak bark tanned leather. There are life and spring in it not found in any other leather. For driving machinery this leather stands first. Long belts should never be made heavy, because the weight makes them swing to a certain extent. The heavier the belt the greater the oscillation. Double-orange tan belts will work as steady as ribbons up to 350ft. long.

---

* Gas Engines. By William Macgregor. London: Symons and Co.

As to which side of a leather belt ought to run next the pulley, Mr. Tullis points out that although it is well known the "grain" side gives the best results at first, it is better to put the belt on in the natural position, for it will have a longer life. If the boiled linseed oil is applied as he recommends, the flesh side will become as smooth as the "grain," and quite as much driving power will be obtained. Mr. Tullis states further that with the flesh side to the pulley the belt is more pliable, and a strip of leather well pulled will curve naturally with the flesh side inwards, thus teaching what practice proves to be correct. A properly-made joint is, however, of the first importance, and, according to Mr. Tullis, a good butt joint with the holes punched to the diamond pattern, and well laced, is as good as any.

Referring to the patent leather chain-belting, or link belting, which is "arched" to suit the curve of the pulley face, Mr. Tullis says that no unequal strain comes upon the rivets, as the belt is made thicker at the edges than in the centre, to suit the curve of the pulley—all that is needed for guide being a template of the pulley. This kind of belt, it is asserted, will transmit 25 per cent. more power than a flat solid leather belt of the same width; because, in Mr. Tullis's opinion, a flat belt always retains a cushion of air between itself and the pulley, which air escapes between the links of the chain belt. A simpler method would be to perforate the periphery of the pulley; but the fact is the link belt has other advantages than spaces for the escape of air. The joint is made by riveting the links, which leaves a belt without a visible joint, and perfectly endless, running straight and steady at any speed. Mr. Tullis has a good word for cotton belts, for they are used in the works with which he is connected, and are exposed to the weather, the only protection being a coat of boiled linseed oil applied every two months; but they are protected from fraying at the edges by Tullis's patent projecting leather edge, which is riveted on with copper wire, and takes the thrust of the shifting fork. With regard to leather ropes, which have been introduced in various forms, Mr. Tullis makes the following remarks, but confesses that none of the devices have been able to compete successfully with cotton or hemp ropes:—There is the ordinary cable-laid hide rope, the strands of which soon cut themselves into pieces by pressure and internal friction. There is also the "Combe" rope, which is made of a multitudinous body of long leather strands twisted together; the friction and pressure also soon cut them up. Then there is the V-shaped solid leather rope, which is much too stiff and hard. The bottom plies get all cut and broken by the outside strain. There is the V-shaped rope with two or more plies of solid leather, with friction sections riveted on these plies. The openings left between these sections are meant to make this rope more pliable, and less liable to cut. It has done good work, but is not a success. There is the square solid leather rope that is now being made, the faults of which are the same as those of the solid leather V-rope. However, there is nothing like perseverance. The outcome of this desire to improve is the patent V-shaped chain rope. This rope seems to possess all the qualities required to enable it to become the driving rope of the future, for it can be put on or shortened in a few minutes, it works well over pulleys of any diameter, can be made to fit any shape of groove, and gives four times the working contact of a round rope. The fact that great differences of opinion prevail shows conclusively that belting, after all that has been said and written about it, is not thoroughly understood, and it would be to the advantage of power users if a series of exhaustive experiments were made in order to obtain some thoroughly trustworthy data.

## THE INTERNATIONAL INVENTIONS EXHIBITION.—XII.

### Philosophical Instruments and Apparatus.

THE student of science who expects to find all the more modern philosophical instruments and apparatus gathered together in this group will be disappointed; but by turning to the preface in the catalogue, which is from the pen of Prof. G. Carey Foster, M.A., F.R.S., he will obtain a brief résumé of the progress that has been made in the last thirty years or so. Scientific instruments may be divided roughly into two great classes—those for producing special physical conditions or particular phenomena, and those for defining the conditions or phenomena or for the observation of the resulting effects. It is in the latter class that by far the larger number of improvements have been introduced, and in every branch of science the fullest prominence is now given to numerical measurements. Walking through the group the visitor will almost of necessity be attracted by the gigantic influence machine which Mr. Jas. Wimshurst, one of the consulting engineers to the Board of Trade, made for the physical laboratory at South Kensington. We described this machine in No. 1035; but it will be worth while to repeat that it is the largest and most powerful in the world, the two discs being of plate-glass $\frac{3}{8}$in. thick and 84in. in diameter, each weighing 280lb. These discs have 16 radial sectors of tinfoil 19in. long, presenting a total metallic surface of more than 500 square inches on each plate. The machine represents the latest improvements of Mr. Wimshurst, and belongs to what is now the leading type. The discs are rotated in opposite directions, and the foil sectors are swept by little brass brushes carried by neutralising rods placed at an angle of 45° diametrically across the discs. The electricity is collected by four combs, two to each disc; but these do not aid in the induction, for if they are removed and the sectors are comparatively close together the sparks will leap from one to another. A 12in. "compound continuous electrophorus," specially designed to exhibit this phenomenon, is placed on the stand, in company with an 18in. laboratory machine, and the separate parts for making the latter, so that all who desire to make a machine of the kind may have an opportunity of thoroughly comprehending its construction. For several years Mr. Wimshurst has devoted a considerable portion of his spare time to the practical study of electricity, and the machine which bears his name has in its latest forms attained to a wonderful degree of perfection. Mr. Wimshurst includes in his exhibit a Nicholson's revolving doubler of 1780, the parent of all influence machines. Prof. Carey Foster, however, says that the earliest application of induction on the "compound-interest principle" appears to have been Bennet's Doubler, 1787, an application revived by Varley in 1860, and since made familiar in the machines of Töpler, Holtz, Voss, and Wimshurst. Specimens of the Voss machine are shown by Becker and Co., of Maiden-lane, Covent-garden, at a stand in a corner of the Swiss Court, or the east-central gallery, so that students will have an opportunity of comparing the two machines. Some members of the Physical Society of London exhibit apparatus which are of necessity in a glass case, and as there is no attendant the visitors will not learn much unless they already know something about the instruments. A similar remark applies to opticians, philosophical instrument makers, and others, who have crowded apparatus into a case and left them without labels or a word of explanation. Two instruments or machines which attract much attention are Edmondson's Circular Calculating Machine for working the four fundamental rules of arithmetic, and Tate's Improved Arithmometer. The former is exhibited by J. Edmondson, of Heath-avenue, Halifax, and is an adaptation of the circular principle, which admits of any product disc being brought opposite any digit on the face-plate while the figures appearing in shallow apertures are easily read. Click springs are dispensed with, and the "eraser" brings to zero any part or the whole of the figures on the circle. The driving handle is conveniently placed, and must be turned in one direction always. The machine deserves the attention of those who have long sums to work in the first four rules of arithmetic. The arithmometer exhibited by Mr. Tate, of Gloucester-street, Clerkenwell, resembles the calculating machine of Thomas de Colmar, which was illustrated in Vol. XXII., p. 642, but materially improved and simplified, while it is a strong and trustworthy apparatus. It is in use in many offices, and at the Exhibition an attendant is ready to show off its capabilities. M. Hedicke and Co., of Adelaide-place, London Bridge, exhibit the interest-calculating machine of Herr Hartmann, which is said to be the first of its kind ever produced. It calculates the rates of percentage from ½ to 5, divided in sixteenths, and from 5 to 10 in eighths, the working being simple, while the results are rapidly obtained. It consists of a scale having on its right a roller containing the numerical table, and on the left a cylinder with a graphical table and two sliding indicators. The cylinder is a supplement to the roller. Mr. T. Dixon, of Buttershaw, exhibits his combined circular, multi-circular slide-rule, which is equivalent to a straight rule 50ft. long, and also the machine for setting out and dividing spiral and circular slide rules. Aston and Mander, of Old Compton-street, Soho, exhibit the slide-rule of the late General Hannyngton (see Vol. XXXVII. for a discussion on slide-rules), and a collection of their own well-known productions. Not many of the opticians show telescopes, but Ross and Co., of New Bond-street, have one or two, and several microscopes, including both monocular and binocular with the Zentmayer swinging tailpiece. Wenham's paraboloid, diffusion condenser, and reflex illuminator are also exhibited. R. and J. Beck, Cornhill, exhibit the "star" microscope (illustrated on p. 406), and, amongst a notable collection, the ribbon-cutting microtome, which is really an attachment for taking away the slices as they are cut, and can be added to most microtomes. This simple addition is a very useful one, as it preserves the slices intact. C. Baker, of Holborn, amongst his exhibits has an ether freezing, Haile's universal, and Rutherford's freezing microtomes. He shows also Stephenson's erecting binocular, and the colorimeter used by Drs. Tidy, Odling, and Crookes in determining the purity of water, or rather its degree of freedom from cloudiness. Newton and Co., of Fleet-street, amongst other exhibits, show Wright and Newton's patent lantern microscope, and the micro-polariscope—the former being the apparatus which was highly commended at the meeting of the R.M.S. on Nov. 12 last, as reported p. 259, Vol. XL., and some details of which were supplied by Mr. Lewis Wright on p. 299, same volume. J. H. Steward, of the Strand and Cornhill, amongst a rather large collection, shows Bridgman's triple lantern, with three and four way plug dissolvers and connections for facilitating the work of the operator; slide carriers of different patterns, range finders in some variety, and a speciality in Kapteyn's chronograph for railway timing, with the scale marked in kilomètres and miles to facilitate the ascertaining of the speed of trains. Belle's registering fluid measure and indicator is also a useful piece of apparatus, as it cannot register until the fluid is actually measured. How and Co., of Farringdon-street, exhibit Dr. Dupré's improved apparatus for applying the heat test to dynamite, gun-cotton, and similar explosives, and also his apparatus for the estimation of urea by means of the hypobromite of sodium. Biological apparatus for the examination of micro-organisms, including incubators, steaming appliances, hot-air chambers, sterilising and cultivating vessels, &c., are exhibited by Griffin and Sons, of Garrick-street, while Deane and Co., King William-street, E.C., show a collection of Fletcher's patent furnaces, forges, and blowpipes. Horne, Thornthwaite, and Wood, of the Strand, show a variety of articles connected with photography and optics, including Ackland's astigmatic disc, Lennox Browne's throat illuminator, and Wood's lime-light microscope. They also exhibit a 6½in. reflector on equatoreal stand, with tangent screw adjustment. Mr. W. F. Stanley, of Great Turnstile, exhibits a number of inventions in mathematical and scientific instruments, and altogether the student has an opportunity of seeing, as it were, at one view a collection of apparatus which it would take days to find by hunting through the shops of the dealers. Amongst the exhibits of special interest may be noticed the stand of Col. Ross, which contains about thirty sublimates on aluminium plates, and a number of other specimens, which will not fail to interest the worker with the blowpipe and the student of pyrology. The gallant colonel also shows his improved patent condensing smoke-filter tobacco-pipes. As everything is clearly labelled at Col. Ross's stand, the visitor can spend half an hour there with pleasure and profit, especially if he understands anything of blowpipe analysis. Professor H. S. Hele-Shaw, of Bristol, but soon to be of University College, Liverpool, exhibits various applications of the sphere and roller integrator, which is to be seen employed for transmitting power in the group devoted to manufacture of textile fabrics. Mr. H. Cunynghame, of Fulham, has a variety of exhibits which will interest the mathematician —for instance, a machine for describing rectangular hyperbolas for use in determining questions of maximum and minimum values in political economy and other sciences, a machine for solving by mechanical means the real and impossible roots of quadratic and cubic equations, and sundry other appliances which would occupy much space to describe. In fact, there are in this group so many pieces of apparatus which it is impossible properly to describe without diagrams, that we must pass over them with the intimation that they are nearly all worth the attention of those interested in the progress of philosophical apparatus. Townson and Mercer, of Bishopsgate-street, have a good collection of chemical and philosophical apparatus; and the Cambridge Scientific Instrument Co. also exhibit some of their productions. Mr. P. Ward, of Fulham, shows a collection of apparatus for illuminating internal parts of the body, for surgeon's use, but some of these can be seen at work, as we stated on p. 378, at the stand of Mr. Swan in the Electric Group. J. J. Hicks, of Hatton-garden, E.C., exhibits a collection of thermometers, hydrometers, &c., McLeod's sunshine recorder, Beckley's self-recording rain-gauge, and a great variety of apparatus, but the principal novelty is the opaque stem chemical thermometer, which facilitates the reading of the temperature. The principle of this arrangement is applied to several instruments, a channel of plain glass being left on each side, so that the position of the contents can be easily seen. The principle is applied to water gauges for steam boilers on the patent of Crossley, Hanson, and Hicks. The tube having opaque enamel at the back, with a line of plain glass, indicates the position of the water very clearly, because the water itself magnifies the dark column, which is the boiler front seen through the plain glass. The line of demarcation is very clear, and can be distinguished without any liability to error. Mr. Hicks also exhibits a lamp for medical men, in which a platinum gauze cap is made incandescent by forcing a blast of air through benzoline contained in a sponge reservoir. Adjoining Mr. Wimshurst's great influence machine, the operation of polishing cylindrical lenses for remedying astigmatism can be witnessed at the stand of Messrs. Pickard and Curry, of Great Portland-street, W., who exhibit the magazine ophthalmoscope of Mr. John Couper, F.R.C.S., and his optometer, with index at back. Both instruments are on the same principle, and the ophthalmoscope contains 72 lenses, divided equally between minus and plus, which are passed in rotation by a simple mechanical arrangement up to the viewing hole, each lens being centred as it arrives at the point of sight. The apparatus is so arranged that it can be placed in any desired position, and from its construction the eye of the ophthalmoscopist is brought nearer to the eye of the patient than the far-point of the latter. Prof. McHardy also exhibits his self-registering perimeter with charts, which registers on either of two scales, and is adopted for ascertaining and recording the fields of direct vision and of indirect vision, and also for determining the angle of squint. Mr. W. H. Harling, of Hatton-garden, E.C., has a notable collection of mathematical, drawing, and surveying instruments, but his principal novelties are bow pens and pencils with spring needle-points, which facilitate the drawing of very small circles, and Grace's patent epicyclic elliptograph and geometrical pen, which will describe mathematical ellipses of various sizes and proportions, from 1¼in. by ¾in. up to 20in. by 10in. and more. The instrument is rather complicated in gearing, but the toothed wheels do not interfere with the operator, and by a combination of change wheels he is enabled to draw an almost unlimited number of symmetrical curves. This instrument is at present practically unknown, but there will be a considerable demand for it when its capabilities are recognised. Mr. Harling also exhibits his "Engineer's Own Level," which is provided with his patent exterior sights for reading "near sights" with accuracy and despatch.

Mr. A. J. Frost, 6, Westminster-chambers, S.W., exhibits Mr. Latimer Clark's transit instrument for obtaining time from sun or stars, which is much cheaper than the old form, and the method of using which is described in Mr. Clark's book which we reviewed on p. 488, Vol. XXXV. A very interesting collection will be found at the stand of Mr. W. Groves, of Bolsover-street, W., where Stroh's curve writer and his sonorous vibration apparatus can be seen; also Prof. Hughes's induction balance and its accessories, his magnetic balance, and a number of test pieces of steel, with sundry other apparatus of more or less interest. Adjoining, Sir David Salomons, Bart., exhibits a case containing models, &c., illustrating his numerous inventions, including a locomotive showing his method of electric signalling to the driver through a centre insulated line, a system which we described some years ago, and which automatically stops a following train, when it enters a section already occupied, by an electro-magnetic arrangement for shutting the regulator.

Messrs. A. Légé and Co., of Turnmill-street, E.C., exhibit Sir W. Thomson's improved tide indicating machine, in which the barometer, thermometer, wind-gauge, &c., are combined, and also Roberts's tide-predicting machine. In these machines the paper is not ruled, but the time is indicated by perforations in the margin, an arrangement which is said to avoid mistakes. Mr. Baldwin Latham exhibits his portable tide-recording gauge, in which the paper is either ruled or perforated by a special striker every hour, the drum being driven round once in twenty-four hours. Dr. Dudgeon shows his diving spectacles fitted with air and glass lenses; an air lens in glycerine to exhibit the refractive power, and his well-known pocket sphygmograph, which we illustrated on p. 104, Vol. XXXIV. We have already in a previous article (p. 337) mentioned Mr. J. Rigg's educational models, which properly should have been grouped in the "elements of machines," and have little space to notice other exhibits, except to point out that there is a notable improvement in mariners' compasses by Mr. F. M. Moore, of Belfast, in which semicircular correctors act on a lowered system of needles, while quadrantal correctors, in the shape of moving iron balls, assist in preventing "heeling errors," and render the adjustment of the compass easy and rapid. Dr. Richardson exhibits models of the apparatus for the painless extinction of life in animals, which we described on p. 378, last volume. W. J. Wilson, F.C.S., of Ealing Dean, exhibits a harmonograph, with specimens of the curves produced by it, and there are in the group a variety of instruments of more or less interest merely to catalogue which would exhaust our space. The student of science, even if he does not find apparatus he particularly wishes to see, will find much that will attract his attention, and many exhibits that deserve careful notice.

## ENGINE-MAKING AT HOME.—VIII.

### The Piston and Cross-Head.

HAVING the cylinder both bored and faced, chest and covers and glands fitted and holes drilled, perhaps it would be well, before preparing any more attachments, to bolt these parts together. This reminds us that we require a number of bolts of various sizes, and as such repetition work is rather tedious, we will consider the best way to get through it.

One circumstance is favourable: none of our screws are very small, and therefore not so trying

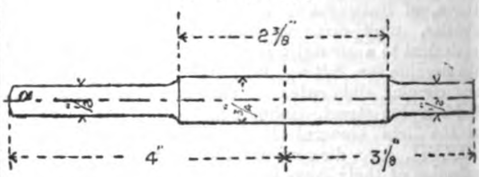

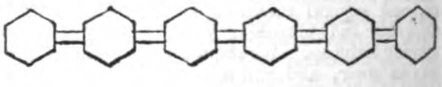

FIG. 96.

to one's patience as the toy screws of the model maker's. I should prefer, also, to make all screws of steel wire, in preference to iron or brass. Small screws when made of wrought iron are apt to bend, and brass, though easy to work, looks common in engine work; while steel takes a clean, keen thread, resists liability to twist off, or strip, and keeps a high polish.. The labour of screw-making consists chiefly in turning down from the diameter of the head to that of the screw. Each screw is better turned separately, to avoid the spring inseparable from turning a long strip of slight metal, and the best way to chuck is either between centres using a specially small driver for the purpose, or holding the head in some type of bell or self-centring chuck, and allowing the opposite end to run on the dead centre.

The best way, I think, to cut the nuts is to get a strip of metal of a thickness and width suitable for a single nut, but long enough to embrace a dozen or more, and to mark them out in line, leaving a space between each sufficient to get a hack saw in—to punch the centre of each for drilling, to drill and tap them all while in the plate, and then to saw them out afterwards; finally to thread them in batches on a screw, and file the hexagon flats off altogether, using the file length ways. The chamfer on each nut must be added afterwards, singly in the lathe. If brass nuts were used, they would be cast in a string, Fig. 96.

The screws required for present use are shown in the figures. Of Fig. 97 we require four for bolting down the cylinder; of Fig. 98, six for the *bolt*-holes in the cylinder flanges and covers; of Fig. 99, six for the *stud*-holes in the same; of Fig. 100, five for the steam-chest flange; of Fig. 101, three for the cylinder gland; and of Fig. 102, two for the gland of the steam-chest.

It will be as well to bolt these parts together at once, and afterwards temporarily remove any one section as required. If the instructions given in the last have been followed, there will be no material inaccuracy in the parallellism of the cylinder foot, so we shall bolt that down to its place on the bed, taking, however, the precaution to try a straight-edge through the bore, to see if it is lineally true, both with the face and the edges of the bed, before drilling the holes in the latter.

Fig. 103 shows the position of the holes in the bed for the cylinder studs, those in the cylinder foot being placed equi-distantly from its transverse centre, or so that the cylinder centre shall measure 7⅛in. from the centre of the first pair of guide-bar bosses. In the other direction, the position is fixed by the recess A, and the corresponding strip upon the cylinder foot. It would be more convenient, in one respect, to use bolts in this instance, and to lift the bed up, and bolt from underneath, for the steam-chest flange comes down in the way, and prevents our using a straight spanner on that one side. Still, it is better not to move the bed from its permanent fixing, but to make a bent spanner out of a bit of wrought iron for temporary use only to clear the flange, and put in studs through the cylinder-foot into the bed.

The piston, piston-rod, crosshead, slippers, and slipper-pin (Fig. 104) may now be taken together and fitted up. The piston in so small an engine is best made solid, with Ramsbottom rings. It will be turned to 3¼in. diameter, and bored to receive the screwed end of the piston-rod. Two grooves will be turned out to take the spring rings, which rings may be made by turning a short cylinder of cast iron, steel, or brass to 3$\frac{5}{16}$in. outside diameter, 3in. inside diameter, —cutting off two rings $\frac{3}{16}$in. in thickness, and sawing them either on the slope simply (Fig 105), or with a shoulder (Fig. 106).

Turn the piston-rod of steel accurately to $\frac{7}{16}$in. diameter (Fig. 107). If Whitworth gauges can be borrowed, it is better to turn all rods and bore their bearings to gauge rather than with calipers simply. The piston-rod is one of the parts which should fit well; hence it becomes necessary to take light cuts with sharp tools to avoid the risk of spring in the rod, which would be as great an evil as a slack fit; and to finish with a fine file, sliding the gauge along to get equal diameters in every section. When the piston is brought up against its shoulder, and the nut screwed up, a hole (Fig. 104) is drilled through nut and screw, and a pin driven through to prevent the nut from working back and becoming loose.

The cross-head (Fig. 104 A), made in brass, or, if preferred, from a piece of wrought iron, will be fitted up after this fashion:—Run a line with a scribe down the centre of the face, *a*, of the forging or casting. Bolt the opposite side on the slotted face-plate, or grip it with the dogs of the jaw-chuck, packing at the back until the axial centre-line is parallel with the chuck-face; then turn the outer face, bore the holes to ¾in., and with a small bent tool passed through the outermost hole turn one of the inner faces—the one which shows outwards. Also skim the bossed edge of the facing to 1¼in. diameter. Re-chuck on the plate by this turned boss, and repeat the operation of facing and turning upon the sides opposite to these just done. Then screw one boss face against an angle-plate, and adjust the latter until the longitudinal centre line coincides with the lathe centre, the circular portion standing outwards. Fix a drill in the slide-rest, and drill up the hole for the piston rod. Skim over and polish the outside, and the non-bearing parts of the cross head, and proceed to attach it to the rod.

The rod may be secured in one of two ways: either by means of a screwed, or a cottared end. If the former, the screw will be equal in diameter to the rod at the bottom of its threads—that is, a ½in. screw (Fig. 107) would be required. If cottared, that end should be enlarged to $\frac{9}{16}$in. diameter, to compensate for the weakening effect of the cottar way. This would be cut by drilling holes in line, and opening out the slot by means of a small chisel and file. The cottar should measure ½in. by ⅛in., and be made in steel.

The cross-head pin, or "gudgeon" (Fig. 108) should be turned of steel to the dimensions, and should be a tight fit in the holes in the cross-head. The prolongation at *a* is to take the eye of the pump plunger.

The two slippers will be filed parallel to ⅞in., and tried well with calipers, the accuracy of the shoulders *b*, *b* being tried with small metal winding strips. When these bearing surfaces are true, we shall employ them for the accurate production of the other working portions. The block will be screwed with its back side to the face-plate, being clipped by the flanges or shoulders,—the parallelism of the shoulders with the plate checked with internal calipers, and the parallelism of the bearing faces with the axis of the lathe being checked either by set square from the plate, or by the use of an angle plate for chucking. The centre of the block measured from the filed bearing faces and from the ends is indicated by a centre punch mark, and this also is adjusted until it corresponds with the centre of the lathe. Then the face is skimmed over, and the hole bored with a ½in. drill. By means of this face and hole, the block is rechucked, and the opposite or inner side faced, not forgetting to round the inner edge of the hole. If these successive operations are carefully performed, all the faces will be parallel, and at right angles with each other. We might, of course, have reversed the mode of operations, boring the hole first of all, and driving the block on a mandrel, have turned the faces thus, filing the bearing parts afterwards; but I think the first plan the better of the two.

## THE MECHANICAL TELEPHONE.

ON Saturday last a new mechanical telephone, on the old principle of the chip boxes and string, but with several important improvements, was exhibited to members of the Press at 4, Ludgate-circus, E.C., where it can be seen and tested by anyone interested. The new telephone is the invention of Messrs. Knudson and Ellsworth, two American gentlemen who have succeeded in converting Hooke's wire telephone into a practically useful means of transmitting and receiving messages over distances of about two miles. As our readers know, there is not much difficulty in working the simple telephones when the wire or string can be kept straight as well as taut; but Messrs. Knudson and Ellsworth have not only succeeded in overcoming the difficulty of taking wires round angles, but have also discovered a material for making the vibrating diaphragm which answers admirably. In a simple wooden box they secure firmly a disc about 6in. in diameter, made up of thin strips of willow, interlaced in the fashion of wicker-work, and varnished to preserve it from the effects of atmospheric and other moisture. In the centre of this disc is a metal plate about 2in. in diameter, with a small washer supporting a cross pin, to which the wire is attached, and by means of which it can be tightened. With such an instrument as that, nearly the whole area of the diaphragm being exposed through the perforated cover, words are heard with distinctness and precision even at a distance of several feet from the instrument, which is of course both receiver and transmitter. The greatest improvement, however, is the method adopted for taking the connecting wire round angles, for the wire must be perfectly free to transmit the vibrations. The patentees accomplish that in an ingenious manner by supporting indiarubber corks on the wall brackets, and passing through them wire loops, which hold the line wire at the requisite tension, and with two bends instead of one. At first sight it might be thought that two bends would deaden the vibrations more than one, but as a matter of fact, what with the rubber cushion and the carefully adjusted angle of bend, there is little loss of vibration, and speech can be heard distinctly between Ludgate-circus and Chancery-lane, a distance of about 500 yards, with, as we need scarcely say, a large number of unavoidable angles. In order to show how easily the wire can be led in all directions without interfering with the transmission of sound, a line has been erected at 4, Ludgate-circus, between two rooms, and altogether there are nine bends; but, notwithstanding, speech can be heard with practically perfect distinctness. Telephones of this kind should be found very useful in large works, in railway stations, in hotels, and on board ship, for the signals are clear and distinct; there is practically no buzzing, and once properly fixed, there is nothing to get out of order.

## ON THE WARPING AND CRACKING OF CASTINGS.*

WHEN a casting comes out of the sand in a different shape from what the pattern was in in the mould, it is caused by unequal contraction, some parts of it having cooled faster than others. This is usually caused by some portions of it being heavier than the rest. After the light parts are cold and done shrinking, the heavy parts are still hot, having yet to shrink, and in doing so draw the light parts with them. When the casting is of such design that it cannot bend, then it breaks, or cracks. In Figs. 1 and 2 are shown a section and top view of a truck wheel—what is known as a soft wheel. In trying to chill the rim it was found that the arms would crack every time. This was caused by the rim cooling first and the hub last, leaving a strain upon the arm. Digging out the core and cooling the hub with water did not change the result, so the following plan was tried with success:—A chill was made to suit each end of the hub, and the wheel cast with them on, as shown in Fig. 1. This had the desired effect, for none of them have cracked that were cast in this way. It is a case where the same amount of iron was in the hub each time, and shows the good effects of cooling. The chills do not come over the ends of the hubs, so it does not interfere with their being faced off. Here there is no chance for the arm to bend, so it cracks, and is a small illustration of the great strain castings are sometimes subjected to. For, calling the sectional area of the arm 2in., and the breaking strain of cast iron 31,829lb. per square inch, we have 63,658lb. exerted in pulling the arms apart. What applies to the above wheel applies also to pulleys. If the arms of a pulley crack, the rim has cooled first and the hub last, leaving the arms in tension or the rim in compression. The old style of curved arm was intended to remedy this, but it only partially did so. If the rim cracks, which is not so often the case, the hub has cooled first and the rim last, which leaves the arms in compression and the rim in tension. This is shown to be the case in the flywheel, where, if the rim is not cooled the arms have a tendency to buckle or get dishing. In pulleys that are of such a design that the arms have a tendency to crack, they may be benefitted by chambering out the hub; that is, making the core larger in diameter for a short distance in the centre, which makes the hub lighter, digging out the core as soon as cast, and also gating in two opposite places on the rim, which keeps the hot iron in the rim and allows the cooling iron to run to the hub.

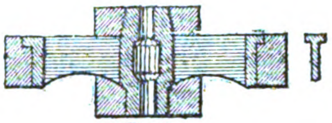

Fig.1

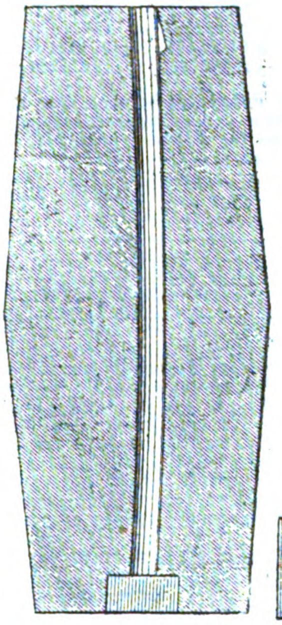

Fig.3

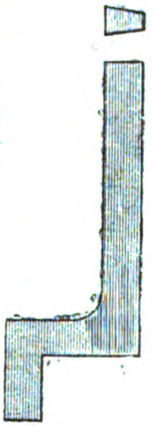

Fig.4

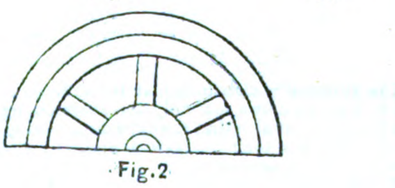

Fig.2

In casting the counter weight with a 2½in. hole through it, as shown in Fig. 3, there is often trouble in keeping the core straight, so much so that in the first two that were cast the sustaining bolt, 2in. in diam., had to be heated red hot and driven in to accommodate itself to the curved hole, this was caused by the core prints on the top and bottom holding the core and ⅝in. core rods firmly, so that it could not expand up or down, and it therefore bent sideways, to make up for its increased length. To remedy this the core print was continued through the cope, and made large enough to be a loose fit. Some pieces of cloth 8in. wide were given a coat of paste and wrapped around the top end of the core, making ⅛in. thickness on each side, when it was blacked over and dried. This projected into the casting 4in. where the iron is liquid for some time and up into the core print 4in. where the iron sets almost as soon as the mould is full; the pasted cloth burns away and leaves a space of ⅛in. on each side, which acts as a stuffing box, and allows the core to expand upwards freely.

In an air-chamber, kettle, or any brick core that acts as a rounding or spherical top where the iron runs over it, there is often trouble caused by the loam expanding, the part that is hot expanding or buckling over the parts that are cold. This, though it may not condemn, yet hurts the appearance of what might otherwise have been a nice-looking casting. A good plan for this is to saw a groove over the top of the core $\frac{3}{16}$in. wide down to the brick so as to divide in quarters. Also another groove around the core to meet them the length of the radius down, measuring from the centre on top. This leaves a space for the expanding loam to fill, and if not quite filled up it is easily chipped off. The loam for a core of this kind should be mixed as open and porous as possible, just so that the iron will not cut it when pouring.

A tedious operation about a brick core is to cut out a row of bricks after the casting is poured, to allow it to contract. This trouble may be avoided by building in a shrinkage piece, as shown in Fig. 4. A chain is attached to it at the lower end by a clevis and bolt, the chain running under the opposite side of the bottom plate through an elbow to the top of the pit. Soon after the casting is poured, hook on to the chain with the crane and pull out the shrinkage piece, which leaves a space of 2in. wide for the casting to shrink on.

The most important item connected with this subject is the iron, what is known as the regular mix in a foundry. If this is not right, nothing will be right. Whole heats of pulleys have been spoiled by a slight change in the mixture. The regular mix should have, besides the other properties required, that of a minimum of shrinkage. This is best accomplished by using three or four brands of iron. When a new lot comes in, use, say, one-sixth of it for one heat, cast some test bars 4ft. long by 1in. square; compare these with a known good quality as to shrinkage, when more or less of it can be used accordingly.

## ON TRIPLE OBJECTIVES WITH COMPLETE COLOUR CORRECTION.*

By Charles S. Hastings.

THE prime defect in the large refractors of the present day is the secondary spectrum. This, arising from the irrationality in the spectra produced by the crown and flint glass, hardly noticeable in small apertures, detrimental in telescopes of medium power, is positively obnoxious in the large instruments, and will speedily put an end to further increase in dimensions. On this account there have been many efforts to produce two kinds of glass differing sufficiently in dispersive power which would still yield mutually rational spectra. As far as I know, we are now no nearer success in this direction than when Brewster investigated the subject 50 years ago. Can we secure the same end by increasing the number of glasses in the objective? Theoretically, since a new disposable constant for colour change is introduced with each lens in the system, the answer is evidently affirmative; but if we limit ourselves by the condition that the construction shall be practicable—*i.e.*, that there shall not be too many lenses, and the curvatures shall be moderate, the conclusion is not so ready. On entering the discussion we will assume three as the limiting number of lenses, and $\frac{1}{10}$in. the focal length as the minimum radius of curvature.

---

* By T. H. Radcliff, in the *American Machinist*.

* From the *American Journal of Science*, Art. LIV. No. 108, December, 1879.

The formula for the focal length F of three thin lenses in contact is, if we set $\phi = \frac{1}{F}$:—

$$\phi = (n' - 1)\left(\frac{1}{r} + \frac{1}{r_2}\right) + (n'' - 1)\left(\frac{1}{r_3} + \frac{1}{r_4}\right) + (n''' - 1)\left(\frac{1}{r_5} + \frac{1}{r_6}\right)$$

Where $n'$, $n''$, $n'''$ are the indices of refraction for the three materials used, and $r_1, r_2 \ldots\ldots r_6$ are the radii of curvature for the six surfaces successively. We may write this more concisely for our end, as follows—

$$\phi = (n' - 1)\,A + (n'' - 1)\,B + (n''' - 1)\,C,$$

calling A, B, and C the *curvature sums* of the first, second, and third lenses respectively.

The problem then, succinctly stated, is to find values of A, B, and C; no one of which shall be more than thirty when $\phi = 1$, and which shall make $\phi$ independent of the wave-length of light transmitted.

If $n$ can be expressed as a function of any variable $x$ of the form—

$$n = A + B f_0(x) + \Gamma f_1(x).$$

The problem has its mathematical expression in the equations—

$$\phi_\lambda = (n'_\lambda - 1)\,A + (n''_\lambda - 1)\,B + (n'''_\lambda - 1)\,C = 1.$$

$$\frac{d\phi}{dx} = [B' f_0'(x) + \Gamma' f_1'(x)]\,A + [B'' f_0'(x) + \Gamma'' f_1'(x)]\,B + [B''' f_0'(x)] + \Gamma''' f_1'(x)]\,C = 0.$$

But since the latter must hold true for all values of the variable $x$, the final conditions for perfect colour correction are—

$$\left.\begin{array}{r} (n'_\lambda - 1)\,A + (n''_\lambda - 1)\,B + (n'''_\lambda - 1)\,C = 1. \\ B'A + B''B + B'''C = 0. \\ \Gamma'A + \Gamma''B + \Gamma'''C = 0. \end{array}\right\}$$

the only practical limitation being that neither A, B nor C surpasses thirty as a maximum.

As to the choice of the variable $x$, the most natural suggestion is the wave-length of light, using the first three terms of Cauchy's well-known formula as an expression for $n$; but there are two objections to such a course, the first and most important being that three terms of this series will not express the values within the necessary limits of accuracy, and the other lies in the great labour requisite to compute the constants. I have, therefore, chosen to take the value of $n$ for some one material as a standard, and compute by the method of least squares the values for other materials as functions of this. The standard selected is Feil's Crown glass, No. 1219, which I have studied and described, with four other kinds, on page 273, Vol. XV. of this Journal.* The reason determining the choice is the greater accuracy of our knowledge of its constants over that of any other light glass. The form of the function is a trinomial of the second degree, thus:—

$$N = A + Bn + \Gamma n^2 \ldots\ldots\ldots\ldots\ldots\ldots (3)$$

Doubtless, by not restricting it to the first and second powers of $n$, a formula might be shaped which would make the differences between the observed and calculated values less; but as that could be attained only at the expense of much greater labour in determining the various values of the constants, and, moreover, as the errors of observation are generally greater than those of the formula, it seems unadvisable to modify it.

In this discussion I have included all the different varieties of glass the optical constants of which I have been able to find given with the requisite accuracy. Unfortunately, there are but few. Besides the five which I have determined, and are cited above, viz.:—

| | | |
|---|---|---|
| Feil's Crown, | 1,219 | α |
| " Flint, | 1,237 | β |
| " Flint, | 1,241 | γ |
| Crown, | A. | δ |
| Flint, | B. | ε |

are included the seven of Fraunhofer†, viz.:—

| | | |
|---|---|---|
| Crown | 13 | ζ |
| Crown | 9 | η |
| Crown | M | θ |
| Flint | 13 | ι |
| Flint | 3 | κ |
| Flint | 30 | λ |
| Flint | 23 | μ |

Six of Van der Willigen* (one closely resembles my A above, while two others are almost exactly alike), viz:—

| | |
|---|---|
| Crown, Merz, No. III. | ν |
| Crown, Merz, No. IV. | ξ |
| Flint, Steinheil, No. II. | ο |
| Flint, Merz, No. V. | π |
| Flint, Hoffmann, No. I. | ρ |
| Flint, Merz, No. II. | σ |

And finally one of Ditscheiner†—

| | |
|---|---|
| Flint | τ |

These are further measurements of 18 different prisms by Dutiron,‡ but so inaccurate as to be worthless for our purpose.

In the order in which the glasses are named are entered in Table I. the values of the constants for (3).

TABLE I.

| | A. | B. | T. |
|---|---|---|---|
| α | + 0· | + 1· | + 0· |
| β | 22·3186075 | − 29·1759937 | 10·2399102 |
| γ | 14·0097123 | − 17·9513549 | 6·4320057 |
| δ | ·5679958 | + ·2172063 | ·2681091 |
| ε | 21·026827 | − 27·430617 | 9·645678 |
| ζ | ·5749543 | + ·2333290 | ·259890 |
| η | ·9025943 | − ·2110704 | ·411148 |
| θ | 5·2924649 | − 6·1318968 | 2·4193199 |
| ι | 19·6074744 | − 25·7440377 | 9·1597811 |
| κ | 20·7768050 | − 27·0625275 | 9·5093547 |
| λ | 24·6152640 | − 32·2820439 | 11·2916241 |
| μ | + 25·4950932 | − 33·4611946 | 11·688423 |
| ν | 2·250818 | − 1·973145 | 0·983738 |
| ξ | 2·737385 | − 2·679993 | 1·241673 |
| ο | 19·541685 | − 25·438209 | 8·976709 |
| π | 27·444400 | − 36·035067 | 12·537277 |
| ρ | 43·623628 | − 57·822556 | 19·899438 |
| σ | 69·141334 | − 91·827575 | 31·313410 |
| τ | 19·960275 | − 26·041640 | 9·196286 |

If we tabulate the differences between the observed values and those derived by substitution in the formula, we have the following expressed in units of the sixth place:

The indices of the following groups are only given to five places of decimals, and are evidently made with much less care than the others.

By taking from Table I. the constants for any three glasses, and substituting them in formulas (2), we obtain values of A, B, and C, which would give complete colour correction; but in general the values would not all be below thirty—the limiting maximum. Of those, however, which satisfy this condition, I select four cases, confining myself to these four, not because it exhausts all the serviceable combinations, or even gives the smallest values for the curvature sums, but because it introduces eight out of the nineteen glasses which are most useful. They are—

| | | | |
|---|---|---|---|
| Case I. | α | β | ι |
| " II. | ν | π | ο |
| " III. | ν | π | τ |
| " IV. | ξ | π | ο |

giving values for the curvature sums:—

| | A | B | C |
|---|---|---|---|
| I. | 3·47026 | 7·20807 | − 8·35472 |
| II. | 9·47513 | 14·28004 | − 21·23665 |
| III. | 7·58585 | 11·57425 | − 16·59076 |
| IV. | 11·67459 | 18·10299 | − 27·22301 |

Substituting these values in the general formula (1), we derive for F the following, the first column giving the Fraunhofer ray for which the focal length is computed:—

TABLE III.

| | I. | II. | III. | IV. |
|---|---|---|---|---|
| A | — | 1·00002 | — | 1·00000 |
| B | 1·00000 | ·99949 | ·99989 | ·99968 |
| C | ·99999 | 1·00043 | 1·00102 | 1·00053 |
| D | ·99999 | 1·00026 | 1·00052 | 1·00005 |
| E | 1·00024 | ·99992 | ·99942 | ·99993 |
| F | ·99999 | ·99988 | ·99951 | ·99999 |
| G | ·99999 | 1·00002 | 1·00030 | 1·00000 |

To exhibit more distinctly the improvement in this form over the double objective, I arrange the differences in the above values between each, and the true focal length of that system in a table, supplementing it with a sixth column in which are entered the corresponding differences for a double objective of glasses *a* and β with its best colour correction, and having a focal length of unity.

TABLE II.

$n - N$

| | A | B | C | D | λ 5614 | E | F | λ 4548 | G | *h* | H |
|---|---|---|---|---|---|---|---|---|---|---|---|
| α | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| μ | — | + 19 | + 10 | − 34 | — | − 30 | + 24 | — | + 30 | — | − 19 |
| ν | + 23 | + 19 | − 22 | − 42 | — | + 14 | + 20 | — | + 13 | + 19 | |
| ξ | + 21 | − 3 | − 16 | − 15 | — | + 15 | + 11 | — | − 10 | + 22 | |
| ο | + 38 | − 27 | − 13 | − 25 | — | + 2 | + 28 | — | + 15 | − 19 | |
| π | + 54 | − 16 | − 37 | − 34 | — | − 9 | + 28 | — | + 29 | + 17 | |
| ρ | + 40 | − 19 | − 30 | − 19 | — | + 11 | + 25 | — | + 4 | − 11 | |
| σ | − 60 | − 47 | − 26 | + 25 | — | +119 | +116 | — | + 32 | − 92 | |
| | | − 8 | + 26 | − 10 | − 34 | − 0 | + 43 | — | + 8 | − 26 | |

The systematic distribution of the differences in the first group shows not only the shortcoming of the formula, but also that the extreme accuracy indicated by the probable errors attached to the indices is not imaginary.

The accuracy of the second group is also great, but much inferior to the first. Occasional abrupt changes, as in that of ι D to ι E in Table II., can only arise from erroneous values in the indices. Here we recognise at once that $n_E$ must be about thirty too great.

TABLE IV.

| | I. | II. | III. | IV. | V. |
|---|---|---|---|---|---|
| A | — | + 2 | — | − 3 | + 135 |
| B | + 1 | − 53 | − 22 | − 35 | + 66 |
| C | 0 | + 41 | + 91 | + 50 | + 41 |
| D | 0 | + 28 | + 41 | + 2 | + 0 |
| E | + 25 | − 10 | − 67 | − 10 | + 13 |
| F | 0 | − 14 | − 60 | − 4 | + 73 |
| G | 0 | + 2 | + 21 | − 3 | + 287 |

The large differences in F E is owing to an erroneous value of $n_E$ in Fraunhofer's Flint 13.

The greater differences in other cases are to be attributed to inaccurate measurements of the optical constants, inaccuracies which are most marked in Ditscheiner's determinations. It may be noted that only in the first two groups are the indices given to six places of decimals, and whatever the errors may be, they are multiplied by large factors in all but the first case. That these differences do not represent any outstanding colours we may be sure from their non-systematic character.

The problem is then solved generally, and shown to be quite practicable in the case of a number of known varieties of glass. Of course, in its practical application, this process should be used to yield a first approximation only, since the thicknesses and distances of the lenses are neglected; but having this, there is no difficulty, other than the laborious character of the computations involved, in determining by successive approximations the values of all the radii requisite to secure complete colour correction and at the same time eliminate spherical aberration. As in the case of the double objective, after satisfying the conditions of given focal length of colour correction and elimination of spherical aberration, we have one arbitrary condition to impose, so in a triple objective we have two arbitrary conditions to impose. In my opinion, were we using materials that required large curvature sums, it would be advantageous to utilise these conditions in making two of the lenses bi-convex and bi-concave, thus rendering the necessary thickness of the materials a minimum.

‡ Comptes Rendus, XXIX. pp. 632–636. Poggend. Annal. LXXIX. pp. 335—336. Annales de Chimie, XXVIII. pp. 176—210. These incredible values, which are extensively quoted in prominent textbooks on optics, have given me a deal of trouble, used as they are in several places to discuss the defects and possible improvement of the double objective. Only by the merest chance I found on the last leaf of the Annales de Chimie, XXVIII. pp. 201, 502, a set of corrections to *all* the values. These new values are less fantastic, but still the errors are large, and even indicated anomalous dispersion is not wanting.

These results are directly opposed to those of a recent writer in this journal.* But his conclusions arise from erroneous calculation. Not only does his interpretation of his equation (12) imply the manifest absurdity that in a system of infinitely thin lenses in contact its properties are determined by the order of the lenses, but the interpretation is impossible. True $A_2$ should have an opposite sign to $A_1 + A_3$, but that asserts nothing as to likeness of the latter symbols in sign. Thus $n$ in eqn. (16) may be negative, and consequently his subsequent reasoning is fallacious, for in that case $n$ does not have to be infinite to cause equation (27) to vanish. I may add that the origin of the confusion is in making the ratio $\frac{D}{E}$ in equation (9) constant; it may be, and, of course, should be, indeterminate.

Professor Harkness has made another mistake, founded upon inadequate experiment, which has so important a bearing on the theory of the double objective that it should not be allowed to pass uncorrected. His statement concerning the condition for colour correction is substantially correct, though, in my opinion, it is not self-evident, but requires proof. This proof I shall supply in a forthcoming number of the *American Journal of Mathematics*. His experiment, however, directly contravenes this principle, for he finds that the focal plane does not correspond to the minimum focal distance, but to something greater. The source of error is the introduction of a variable element in the system—namely, the eye, which would adjust itself differently in observing the star and its spectrum. Had the writer used eye-pieces of successively higher power, thus lessening progressively the power of accommodation of the system with his prism, he would have seen his points $\gamma_m$ and $\gamma_n$ approach until they sensibly coincided; or, better still, had he formed his spectrum by a grating (such as a perforated cardboard) before the objective, instead of by a prism between the ocular and the eye, he could not have been misled, since the uncoloured image would serve to control the eye.

Finally, the fourth conclusion is strictly true, though we are not to conclude, as would seem from the text, that the detriment due to the secondary spectrum depends either solely upon the aperture, or varies inversely as the focal length; for though the secondary spectrum remains constant in dimension with a given aperture, and consequently its angular value decreases inversely as the focus, a stellar image (diffraction disc) increases directly as the focal length. Hence, by increasing this element, more of the central portion of the secondary spectrum—i.e., the brighter portion, would be absorbed into the stellar disc. In other words, by doubling the length of the telescope, the secondary spectrum becomes much less than half as offensive.

Johns Hopkins University, Sept. 20th, 1879.

## THE POINTS OF A GOOD LATHE.

LET us consider the common screw-cutting engine lathe, that most widely known and indispensable adjunct of the machine-shop. We say indispensable, because of all the tools in the best equipped machine-shop the lathe is the only tool that could not be dispensed with. Looking through dealers' stocks we find almost as many designs of this tool as there are builders. Some of these designs are very good, some mediocre, others faulty, but none are perfect. It may be considered a bold assertion to make, but we do not hesitate to say that the model engine lathe of to-day—with the exception of a few minor details—is not one whit in advance of its prototype of thirty years ago. The crowning fault with the majority of lathes now on the market lies in the fact that there is not metal enough in the bed itself. This is a serious fault, and has prevented the sale of many an otherwise fairly good lathe. There would seem to be no excuse for this penuriousness on the part of builders when the very low price of pig-iron is taken into account. It is safe to assert that the average engine lathe should have one-third more metal in its bed. And not only this, but the metal should be so distributed as to bring the centre of gravity of the entire tool much lower than it is usually found. Of all the nuisances to be met with in a machine-shop a top-heavy lathe is the greatest.

Another fault with modern tool builders consists in making the top part of the bed too narrow. The bottom part of the bed should be made considerably wider, also, and more spread given the legs. A lathe, as much as any tool, should be built upon the anvil principle, and top-heavy lathes are sure to tremble and weave under high speeds or heavy cuts. A lathe should be a solid, compact tool, and set upon a foundation in keeping with its weight and capacity. The bed should be wider and deeper; the legs should be shorter, and have considerable more spread, and the entire tool made to assume a more squatty appearance. Placing the lead screw on the back side of bed has its advantages as well as disadvantages. It is undoubtedly an advantage to have the lead screw tucked away under the overhang on back side of lathe, out of the way of grease, dirt, and chips, but it is equally a disadvantage to the workman when cutting such pitches as allow of running the carriage back by hand—particularly in short screws—as he is compelled to assume an awkward and uncomfortable position while handling the lock-nut lever. The splined lead screw has its admirers, and some buyers will have no other. It is always placed in front of lathe bed, and this much is in its favour. Still, we are inclined to think it is better to use the lead screw for thread cutting only, and that it should not be used for any other purpose.

The slow process of running the carriage back by belt, when cutting odd pitches, obtains to-day as well as it did thirty years ago. With the exception of a few feeble attempts, builders have done nothing to overcome this waste of time. All screw-cutting lathes should have the lead screw placed in front of bed, and there should be some device attached, which would admit of running the carriage back by hand for any pitch. This, with a properly-constructed and positive rod feed, would bring the entire mechanism by carriage movement and cross-feed immediately under the hands of the workman. Tail stocks are frequently made too short, and we have seen those that were much too light, notwithstanding the very low price of pig-iron. There are some builders who aim to get a regular gradation of speeds, from the slowest out of gear to the slowest in gear. This, of course, can be done, but it can only be attained at an expense of power, and buyers would do well to note that any lathe so constructed has not the same amount of power at which it should be rated. The master wheels should have more breadth of face, and the front journal of live spindle made longer in diameter and somewhat shorter. Builders seem to vie with each other in making long spindle bearings, although at the same time they know that there is no advantage in it, but simply because the market demands that they should be made so. The idea that spindle bearings should be made very long is an exploded fallacy, and it behoves buyers to eschew this notion, and devote their attention to points of greater importance when inspecting a lathe.

In buying a lathe lost motion should be sought for in the cross screws, and the perfect alignment of the lead screw with the half nut is a matter of the utmost importance. If one eighth of a turn lost motion be found in any cross screw, it is safe to presume that the rest of the fitting is of like character. Lathe aprons conceal much rough work and imperfect fitting, and as the buyer has no opportunity of examining this hidden arrangement of wheels, pinions, sleeves, and levers, he should exact a guarantee from the dealer that the quality of this work is in keeping with that which is exposed to view. Tail-stock arbors should have right-hand screws, as it is much easier for the workman to pull on the hand wheel than to push it. Besides, all lathes were formerly made with right-hand arbor screws, and modern left-hand screws for this purpose are a senseless innovation, for the reason that they bother and confuse veteran lathesmen, who have been always accustomed to right-hand screws. Arbor screws should have hand wheels—not cranks. This is obvious to the workman, although it may not be to the designer in pursuit of novelties. If the live spindle centre runs true when thrown in at random, it is a pretty sure indication that all other alignments and fittings are true, and good close work can be expected from such a lathe. Still, we have seen very good lathes that required the live centre always set to a mark. The fact that the lead screw is made of steel amounts to nothing. Steel being free from seams and grit, and being homogeneous throughout, is a cheaper metal for this purpose than iron. Builders also dwell particularly on the fact that all their gears are cut from the solid. Their is no necessity for this enlargement at all. For it is a well-known fact that cast gears are more durable than cut gears, but as the teeth of cast gears cannot be got mathematically correct, cut gears are used instead, because they are cheaper.

Some builders still keep up the fancy scraping craze; in fact, they overdo it. While this sort of ornamentation adds nothing to the working value of a lathe, it certainly costs something, and somebody must pay for it. Fancy scraping and oil stoning, while pleasing to the eye, and apt to catch the unwary buyer, is a positive detriment to keeping the lathe clean. We would rather not have any in ours. To sum up: a lathe should be made of perfectly sound castings. The bed should be heavy and well braced, and quite deep; the legs short and have considerable spread. The cone and back gears should be designed for power instead of regular gradation in speed. The wheels have broad faces and accurately cut epicycloidal teeth, to prevent rattling and backlash. The cone should take a wider belt than is common. The tail stock should have a long bearing on its V's, and a receptacle on back end for tools, chalk, &c. The studs should be so made that change wheels could be slipped off and on without taking off the nuts. The alignment of live and dead centres should be as near perfection as human ingenuity and improved machinery can get. The live centre should not run out of truth more than $\frac{1}{16}$ of an inch, 6in. from the face plate. There should be no lost motion in cross screws. The lathe should have a compound rest if the swing will admit of it, and, where admissible, automatic cross feed. The spindle, arbor, lead screw, and cross screws should be made of hammered steel, the spindle bearings of best brass, and all tap bolts, set and cap screws, of best quality of iron casehardened. A lathe such as we have described would produce true work of all kinds, it would afford the workman pleasure in running it, and although its first cost might seem high, it would be the cheapest in the long run. "*Observer*" in *Age of Steel.*

## OXYGENATED WATER.*

SINCE Schönbein's researches, the process of "grass bleaching" was attributed to the influence of ozone, but the new and very exact experiments of Emil Schoene, together with the earlier labours of Houzeau and Goppelsroeder, have proved that the reactions formerly attributed to ozone really owe their origin to oxygenated water. Repeated quantitative analyses showed that the richness of the air in peroxide of hydrogen varies according to the seasons of the year, the hours of the day, the direction of the wind, &c.; but Schoene attributes a predominant influence to the light. Rain, but especially dew in certain cases, contains a considerable proportion of oxygenated water, namely 0·04 mgm. to 1 litre of liquid; the quantity which the soil receives in this way amounts to 62·9mgm. per square mètre. Although "grass-bleaching" has been known and practised for centuries, and there was plenty of time and labour employed to its improvement, it cannot be denied that this procedure has its many great drawbacks. The success of a bleach upon the meadow can never be foretold to a certainty in a given time; the bleaching always requires a long time, and "time is money." These considerations show what profit would be derived from replacing the natural bleaching by the preparation of a more concentrated form of oxygenated water.

Chemistry offers a numerous series of combinations in which the oxygen is but feebly held, and which easily surrender it to other substances. These oxidising agents can be used instead of the air in bleaching, and those which are practically employed for that purpose are nitric and nitrous acids, permanganic acid, chloric acid, chlorous acid, and finally chlorine, either in a gaseous form or in combination with bases. But all these products, however different from each other, have the inconvenience of more or less attacking the fibres; oxygenated water alone has not this fault; it contains in a more concentrated form the active principle of the best kind of bleaching—that is, of grass-bleaching; it is superior, therefore, to all those products, and may be considered as the bleaching agent that is to rule in the future.

Thenard, in 1818, discovered the peroxide of hydrogen; it was obtained by the action of acids upon barium peroxide in the presence of water. Since then, oxygenated water has been the subject of investigations by Pelouze, Duprez, Balard, J. Thomson, E. Schoene, &c., but without achieving an improvement in the manner of its production; only very dilute solutions were obtained with possible 5 per cent. peroxide contained in them. The pure product $H_2O_2$ is hardly obtainable on account of its utter decomposibility. There are but two ways of concentrating the solutions; either by freezing, or by evaporating in a vacuum at 59°—68° F., over sulphuric acid.

Pure peroxide of hydrogen is a syrupy liquid, of 1·453 density, whose decomposition yields 475 times its own volume of oxygen. Its dilute solutions are

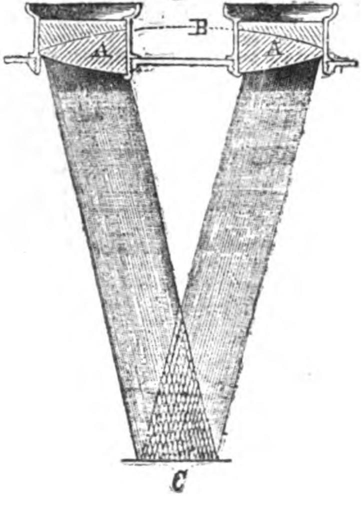
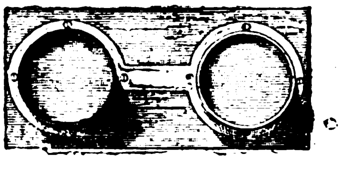
* From a lecture delivered by Dr. P. Ebell at Hanover.

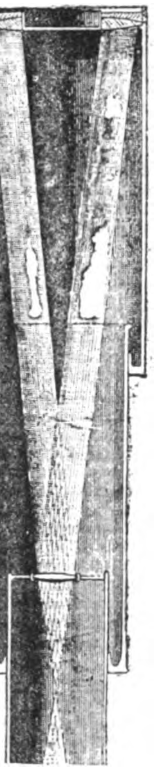
1



2



3



analogous in their action to chlorewater, and can be preserved for months, if kept in the dark at a temperature not above 77° F. They keep better still if a trace of acid is added to them; while alkalies or liquids of alkaline reaction promote decomposition. This inclination of oxygenated water to set oxygen free places it among the oxidisers. There are many substances which provoke this decomposition without undergoing themselves any modification, such as alum jelly, oxyhydrate of iron, charcoal, some metals in a condition of extremely fine division, silver, gold, and platina. With another class of bodies, the oxygenated water behaves like many other oxidising agents—that is to say, it surrenders its oxygen; for instance, with arsenious acid it produces arsenic acid, and transforms the metallic sulphides into sulphates. Upon certain peroxidised substances, finally, the oxygenated water can act reducing; for instance, upon the peroxides of lead and of manganese, which are reduced by its presence to the oxide state.

All chemists who have occupied themselves with this subject are unanimous in predicting a brilliant future for the employment of oxygenated water. Dumas, in 1830, recommended it for cleaning old paintings, because the lights of paintings become black by the transformation of the white lead into sulphide of lead, which being retransformed into sulphate by the action of oxygenated water, the light colours must be restored to their original appearance. Oxygenated water, however, was ignored for a long time, until in 1870 a perfumer availed himself of its bleaching properties, to introduce a 3 per cent. solution of it as a hair dye under the names of "Auricome" or "Eau de Fontaine de Jouvance dorée." About the same time A. Von Schroetter, R. Boettger, Geiger, and Hagen directed the public attention to the therapeutic properties of oxygenated water.

The difficulties of preparing pure oxygenated water on a grand scale, causing its formerly high price, have been at present overcome, so that a 3 per cent. (by weight) aqueous solution can be had at a moderate price and in any quantity. With its excellent bleaching properties and safety of application the road seems to be opened, therefore, for its extensive utilisation in industries.

## OBJECT-GLASS FOR TELESCOPES AND CAMERAS.

THIS invention has a twofold object: to obtain the effect of a lens of large diameter without the labour and expense required for the production of large lenses; and to improve photographic pictures by the use of lenses which serve to intensify the image and produce a stereoscopic effect in the picture. The lens is of compound or double form, each portion being ground to the curvature of a solid lens of the required diameter, and the two parts being held in their support so as to be retained in the same relative position with regard to each other that they would sustain in a solid lens of the same diameter and curvature. The lens is composed of the two parts, A, which are constructed by securing two discs of glass in the same plane, and then grinding them to the curvature of a solid lens of like diameter. These are then secured or set in a frame made of any suitable material. For telegraphs the setting may be of some inferior glass, or it may be, as shown in Fig. 2, similar to those used in opera glasses. The same effect may be obtained by taking an ordinary lens, and by diaphragms or other means, rendering it opaque, except at diametrically opposite portions. It will be understood that in cameras this construction applies to the front or object lens, the condensing lens, C, being applied as usual. This invention has been patented by Messrs. J. A. Smith and A. J. Athay. Further particulars can be had by addressing the latter, at Sparland, Illinois, U.S.A.

## ATMOSPHERIC ELECTRICITY.

THE following notes on atmospheric electricity are given by L. Palmieri in *Biedermann's Centralblatt*:—

1. *Electricity with a Clear Sky.*—When within a circle of about 140 kilomètres in radius, neither rain, hail, nor snow is falling, the electricity at the place of observation is always positive. If negative electricity is observed with a clear sky, downfall at some little distance may be inferred. As regards the daily periodicity of atmospheric electricity in calm, bright weather, two maxima and two minima may be recognised. The first maximum appears at the ninth hour of the morning; the second, which is more decided, a little after sunset. It often continues during a great part of the night. Toward daybreak a minimum appears, and a second, less distinct, in the afternoon. This daily period is easily disturbed by movements of the wind, by a cloud appearing on the horizon, by a mist rising from the somma, and by other causes often hard to determine. It may be asserted that when the maxima are very considerable, or when decided maxima appear at unusual times, the sky on the following days will scarcely be serene. If the sky begins to be overcast, the electric indications grow stronger, and if at the time of the evening maximum the relative moisture increases with a heavy dew, maxima of special intensity and duration may be expected. The general assumption that atmospheric electricity becomes stronger with the altitude has not been confirmed by the observations made simultaneously on Vesuvius and at the observatory of the University. The values obtained on Vesuvius were generally smaller. As regards the yearly periodicity, lower tensions are generally observed on hot summer days. In spring and autumn the indications are stronger. In winter the values are uncertain.

2. *Electricity with a Cloudy Sky.*—In the absence of distant rain, &c., the atmospheric electricity on cloudy days is always positive. It is less intense, more variable, and without a decided daily period.

3. *Electricity in Time of Rain.*—During rain, atmospheric electricity increases considerably, both at the place of observation and at some distance, even though no lightning occurs; this increase begins and disappears along with the rain. Sometimes, if rain is falling at a certain distance, the atmospheric electricity changes its sign once or repeatedly. When the rain is falling, the electricity is positive; this region is surrounded by a zone of strongly negative electricity, upon which again follows a second zone of strongly positive electricity.

4. *Thunder-Rain.*—Between ordinary rain and thunder-rain, the only difference is the more abundant development of electricity in the latter. The raining cloud must be regarded as a constantly flowing source of electricity. There can be no lightning without rain and thunder. The so-called "harvest lightning" is merely a distant storm. The sound of thunder cannot be heard beyond 21 kilomètres (13 miles), while lightning is perceived at a far greater distance.

## DIMENSIONS AND MOVFMENTS OF WAVES.

THE ships of the United States Navy have been engaged for some time in making observations of the dimensions and speed of deep-sea waves. These recorded observations are not so complete and numerous as is desired, and any assistance in this respect will do much to advance one important branch of the science of naval architecture. The observations made where a ship falls in with a single series of approximately regular waves are most valuable, and should be accompanied by full records of the attendant circumstances.

One method of measuring the wave lengths consists in towing a log line astern of a ship, and noting the length of line when the chip floats on the wave crest next abaft that on which the stern of the ship momentarily floats. The ship should be head-on, or allowance made for the departure of the log line from the head-on position. To measure the wave heights, when the ship is in the trough of the sea, and for an instant upright, the observer takes up a position such that the successive average wave ridges, as viewed by him from the trough, just reach the line of the horizon without obscuring it. The height of the eye above the water level correctly measures the height of the waves. To measure very high waves the observer may have to ascend the rigging, while for waves of less height a station on one of the decks may suffice, or some temporary expedient devised for placing the observer near the water level. It is desirable to select a position as nearly amidships as possible, but if it becomes necessary to take a station near the bow or stern, allowance must be made in estimating the height of the eye above water for the deeper immersion which may be caused at the instant by pitching.

The longest recorded wave measured half a mile from crest to crest, with a period of twenty-three seconds. Waves having a length of 500ft. or 600ft., and periods of ten to eleven seconds, are the ordinary storm waves of the North Atlantic. In regard to the heights of waves, the most trustworthy measurements show from 44ft. to 48ft. to be a remarkable height. Waves having a greater height than 30ft. are not commonly encountered. The U.S. Hydrographic Office has blank forms for recording these observations, and would be glad to furnish them to any shipmaster who takes sufficient interest in the subject to make observations whenever the opportunity occurs.

**New Reaction for Digitaline.**—The difficulty of distinguishing by chemical methods between various alkaloids has always been very great. This difficulty, where forensic matters are concerned, necessitates in many cases the employment of vivisection in order to subserve the ends of justice. Digitaline may be certainly recognised chemically by the following method, according to M. Lafon: If a trace of digitaline be treated with a mixture of sulphuric acid and alcohol, of each one part, and if to this mixture a drop of ferric perchloride be added, a beautiful greenish-blue colouration is developed, which lasts for several hours. The most favourable conditions for the reaction are the following:—Use a very small quantity of digitaline; dry the substance with a very small quantity of the mixture of sulphuric acid and alcohol, and warm slightly until a yellowish tint appears; then add the drop of ferric perchloride, which should be allowed to spread out. This reaction is peculiar to digitaline, for M. Lafon has tested the whole of the alkaloids and glucosides usually employed in therapeutics. Morphine produces with ferric perchloride the blue colour, but this only occurs where the reagents are neutral. Digitaline prepared at Darmstadt by Merck, neither in its crystalline nor in its powdered condition, gave the above reaction; so that there is a marked difference between some German digitalines and the French alkaloids, a difference which is said to be shown in the varying solubility of the alkaloids as well as by the physiological effects. Chloroform dissolves but little of the German alkaloids. MM. Laborde and Duquesnel have recently pointed out the different physiological effects of digitaline according to the source of the alkaloid.—*Lancet.*

# SCIENTIFIC NEWS.

FROM Dun Echt Circular, No. 95, we learn that the elements and path of Barnard's new comet (see p. 426), as computed by Mr. S. C. Chandler, jun., from three observations made at Boston, U.S., are as follows:—T May 16·72 G.M.T.; $\pi$ − ☊ 150° 8′; ☊ 91° 28′; $i$ 84° 27′ (mean equinox 1885); log. $q$, 0·39340). The ephemeris for G. midnight, July 25, is R.A. 16h. 52m. 12s.; S. Dec. 14° 32′. The brightness is decreasing.

A year's rainfall at Ben Nevis observatory (including melted snow and hail) amounts to over 152in.—that is, for the twelve months ending with June last. The measures have been taken as carefully as possible at every hour, and the average of the monthly returns since June, 1881, gives a mean annual rainfall on the summit of the Ben of 145·73in., the largest observed at any spot in Scotland. Falls of an inch a day are of common occurrence—about one day in seven; but the largest fall in a month was 25·30in. in December last, and the smallest, 4·85in., in April last.

At the Albert Palace, on Monday last, the electric signalling balloons of Mr. Eric S. Bruce were tried for the first time. These balloons are exhibited in model at the Inventions in Group 25, No. 1913. The invention consists of an ordinary balloon made of a material as translucent as possible (in the case of the one at present on exhibition the material is cambric) in which are fixed a number of incandescent lamps. The balloon is a captive one, and the rope which secures it is also utilised for conveying the electric current to the lamps inside the balloon. The system of long and short flashes of light is adopted, and the experiments were completely successful. It is proposed to continue the exhibitions of signalling for a month. The chief obstacle to be overcome in introducing the electric light into the balloon was that occasioned by the highly inflammable nature of the gas with which the balloon is inflated. Mr. Bruce lectures on the signalling balloon every night before the ascent, and will also lecture on it at the Crystal Palace this afternoon. Mr. Bruce is in communication with the military authorities, who will probably order a trial of the balloons.

The Irish Lights Commissioners, who are making a tour of inspection, visited Mew Island, Belfast Lough, last week. The lighthouse is at the entrance to the Lough, and has an illuminating power of over 2,600,000 sperm candles. Under the superintendence of Dr. Ball a series of interesting experiments were proceeded with. The illumination with the first or ordinary supply, and also with the additional or second quantum, of gas was tested; but the full strength used in very thick weather could not be shown, as the glass reflectors, &c., had been lent to the English authorities for kindred experiments at the North Foreland Light. Those tried were found to be in admirable condition, and the results were in the highest degree satisfactory. The light is one of Mr. Wigham's patent triform group-flashing gas-lights. The Board of Trade directed that oil should be used as the illuminant, and not gas; but the Commissioners of Irish Lights insisted that gas should be used not only as the illuminant in the lighthouse, but also as the motive power for the fog signal, and in the end they carried their point. However, if the gas should fail at any time, there is a very complete set of appliances for illuminating with oil, and these were also experimented with. The gas was turned off, and in a few seconds the lightkeepers had a brilliant illumination with oil.

What is a diaphragm? is a question which has been engaging the attention of a number of experts recently; but judgment, at the time of writing, is deferred. The question arose in connection with a telephone case.

The Council of University College, London, have instituted a professorship of electrical engineering, and have appointed Dr. J. A. Fleming to the chair.

The International Telegraph Congress will meet in Berlin on August 10, and will be attended by delegates from nearly all parts of the world, and by representatives of all the great cable companies. The principal subject for discussion, so far as the public are concerned, is a general reduction of tariffs.

Details of an important geographical discovery in the shape of another great African waterway have been received from the Rev. G. Grenfell, who has proved that the Mobangi, which enters the Congo on its right bank, is probably the greatest tributary of the latter. Mr. Grenfell navigated the Mobangi in the little steamer *Peace*, on a mean course of north by east, from the equator to 4° 30′ N. lat., and left it still an open waterway. At 4° 23′ N., just below the second rapids, he found it 673 yards wide; at no point lower was it less in width. Its mean depth is 25ft., and although the current runs not more than 80 to 100ft. per minute, it means an immense volume of water to find running south at a point so near the supposed sources of the Binué, the great affluent of the Niger. The Mobangi is probably the lower part of the Welle, a river whose course is one of the unsolved problems of African geography. From the notes sent home by Mr. Grenfell it would seem that the Mobangi is navigable the whole way from the Congo to 4° 30′ N., a distance of probably 400 to 450 miles, taking account of the bends. A large map, in ten sheets, of the explored part of the river has just been received at the Royal Geographical Society. This map will appear in an early number of the society's proceedings, and a long narrative of Mr. Grenfell's recent work will probably be published in the next number of the *Baptist Missionary Journal*. It is hoped, moreover, that a full narrative of Mr. Grenfell's explorations will reach England in time to be read at the Aberdeen meeting of the British Association.

The death is announced of Mr. N. W. Posthumus, secretary of the Dutch Geographical Society, and one of the editors of its *Journal*. He was also one of the founders of the Society. Mr. Posthumus was only forty-seven.

On Tuesday last week the steamship *Carrier* made her first trip from Langston to Brading, a distance of eleven miles, carrying a train of twelve railway waggons, weighing, with their loads, about 160 tons. That is the first time in which a train has been carried by a steamship in England.

A trial trip of the *Nashua* took place in New York bay recently, and everything was deemed satisfactory. The *Nashua* is a side-wheel steamer, and has the first compound oscillating engines ever put into a paddle steamer. The cylinders are 42in. and 78in. diameter respectively, with a stroke of 10ft. 6in. They are set below the shaft at an angle of 90° to one another, and both piston-rods are connected to the same crank-pin.

At a meeting of the Coalville Branch of the Amalgamated Society of Railway Servants held last week, after full discussion and consideration, it was unanimously resolved that *iron* crank axles are better and safer than steel.

**New Hygrometers.** — M. Bourbouze has devised two interesting and novel forms of the dew-point hygrometer. It is well known that when water vapour condenses on a plate of glass held between the observer and a luminous point, there appear concentric rings round the point, similar to the halo sometimes seen round the moon in cloudy weather. These hygrometers are based on this fact; and consists of a rectangular tube having panes of thin glass closing the parallel ends. A very sensitive thermometer is plunged into the liquid to a small depth, and when evaporation of the liquid is set up by a current of air, the dew halo forms on the panes, and is observed by looking through them at a luminous point. The halo is red outside and violet inside.

**Menthol as a Substitute for Cocaine.**—Dr. Albert Rosenberg, of Berlin, has found in menthol (*Berl. Klin. Woch.* No. 28), in etherial or alcoholic solution (20 to 30 per cent.), a useful substitute for the expensive cocaine, in cases where local anæsthesia of mucuous membrane—e.g., of nose, pharynx, and larynx—is required. The effect of menthol is not so lasting as that of cocaine, but it appears to have somewhat of a cumulative action; for, when repeated, even after a long interval, the later application produced a longer period of anæsthetics than the earlier.

IT is said that a rich find of silver chlorides has been made on the surface of the Broken Hill claim at Silverton, New South Wales, which is said to run through a lode over 20ft. wide. The chlorides have been found for a distance of nearly half a mile. A great many claims have lately been pegged out along this line of country for miles.

# LETTERS TO THE EDITOR.

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable* J. PASSMORE EDWARDS.

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does' and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

### ASTRONOMICAL — DOUBLE STARS — 53 OPHIUCHI—SELENOGRAPHICAL.

[24503.]—I FEEL truly very much obliged to Mr. Sadler for his kind and prompt answer to my last letter on double stars. I am sorry, however, that through a wrong reading of my declination circle I gave a wrong position of the supposed new double. It is XVh. 32m. + 34° 47′, and this brings it so near to the place of Σ. 1959 which Mr. S. mentions, that I have no doubt but it is the same star. What surprises me is that this star should be considered as of the 8·7 mag., and its *comes* of 10·2 mag. Last night, between clouds, I again looked at it, and I would still have called it, for the least, of the 7th mag., and as its *comes* shone brightly at its side it appeared to me near the 8½ for the least. The distance seemed greater last night; but its position is somewhere between 250° and 260°.

I will try what I can do with the list of doubles kindly given by Mr. S., and report; but I must wait for the absence of the moon and for fine weather, for I suppose they are difficult objects.

The very evening I received the "E.M.," No. 1,059, I looked up 53 Ophiuchi, and saw many more stars than those represented in the sketch of Mr. K. T. Tarrant. I felt sure Mr. T. would add others, and that the following issue would say so. I see that he has found six more. In the diagram I made I find 11 more; but three are out of the line joining G to the *comes* of C, and two others are preceding E. The six remaining are doubtless the six he has seen. My diagram shows four other stars as suspected. One is preceding H, and the three others are between H and the N. companion of K. There are, besides, other glittering points in various parts of this field; but so fugitive, that I found it impossible to take their exact positions.

Has any one observed a darkish spot on the S. extremity of the floor of Cyrillus? That spot contains two small craters of equal size. Schmidt gives only one, and yet his map contains internal evidence that he has closely surveyed this region.

**C. M. Gaudibert.**

### THE DAYLIGHT OCCULTATION OF ALDEBARAN.

[24504.]—I AM much pleased that the communication which appeared from me in a recent number of the ENGLISH MECHANIC had the effect of drawing out from two correspondents very exact accounts of the observation of this phenomenon. At Fleetwood a slight haze was sufficient to prevent its being seen. It is by means of such interchanges of scientific work that amateurs learn to place a value on their performances, and are encouraged to prosecute their researches more diligently. Assuming that Mr. Peek takes his sidereal time from Lyme Regis in accordance with its longitude, I find that the time of immersion, as he observed it, differs by 1m. 43s. slow of that which I calculated for Greenwich by the partially graphic method, and the time of emersion slow by only 26sec., but I feel sure, if he will make the computation for himself according to the principles of my method he will arrive at results still more accurate.

"A. H. S." appears to have been extremely fortunate in his opportunity, and I trust he may favour us with equally interesting details of the daylight occultation of Aldebaran, which occurs on Sept. 29, 1885.

**James Pearson, M.A., F.R.A.S.**
Fleetwood, July 17.

### 100 TO THE INCH — MAGNIFYING POWERS OF A BY-GONE AGE—FAST TRAINS—ERRATUM.

[24505.]—MR. HOLMES (letter 24481, p. 430) in trying to get me on the right path falls into the ditch himself. My quotation from a private correspondent was logically sound as applied to planetary and other objects having a sensible area; for, in this case, it is the intrinsic brightness of the image that is in question—not the total amount of light forming that image. Granting that the image of Jupiter, as seen with a power of 100 on a 2in., is just equal in brightness to the same image with a power of 200 on a 4in. it would be a *reductio ad absurdum* to infer that, therefore the smaller glass shows the same amount of detail as the larger one. The diameter of the image would be, of course, twice as much (and superficial area four times as much) with the 4in. as with the 2in., and it cannot need much reflection to show that the eye would be more vividly impressed with the larger image. But the case of a star is totally different; for here, beyond the enlargement of a flashing point of light into a tiny spurious disc with surrounding diffraction rings, magnification has no other effect than that of increasing the angular distance between the separate components of a double or multiple system. Consequently, the intrinsic brightness of either a bright star or faint *comes* depends upon the aperture of the object-glass or speculum, and nothing else. Further, does Mr. Holmes ignore the quotation from Prof. Newcomb, relative to the size of the emergent pencil of rays, when he says that he finds a 9in. to stand 900 easily enough on stars? Also, I must maintain my argument that the atmosphere does enter into this question; because the atmosphere is always magnified to an equal extent with the object, and its disturbing effect is a factor in the ultimate result—a variable one, truly, but one which can never be eliminated. And I venture to assert, with all conceivable deference to Mr. H., that his dictum respecting "the failure of a 26in. to stand 1,300 (on planets, please) on a steady night as a proof it was defective" is one which few astronomers would be disposed to accept, *experto crede.*

Mr. A. Mee (letter 24477, p. 428) would do well to peruse the following, by Prof. Newcomb, before believing in ancient "giants":—"It has sometimes been said that Sir W. Herschel employed a power as high as 6,000 with one of his great telescopes, and, on the strength of this, that the moon may have been brought within an apparent distance of 40 miles. If such a power was used on the moon we must suppose, not merely that the moon was seen as if at the distance of 40 miles; but that the vision would be the same as if he had looked through a pinhole $\frac{1}{25}$in. in diameter, and through several yards of running water, or many miles of air. It is doubtful whether the moon has ever been seen with any telescope so well as it could be seen with the naked eye at a distance of 500 miles. If such has been the case, we may be sure that the magnifying power did not exceed 1,000."—"Popular Astronomy," 2nd edition, p. 145.

In letter 24487 (p. 432) there appears to be several serious errors. "M. R." is omitted over the section relating to the Midland, and "1h. 0m." cannot be the correct time of four expresses between Kettering and Nottingham. The distance, too, between Nottingham and Kentish Town, via Kettering, is surely not 142½ miles? From Nottingham to London, via Leicester, the distance is only some 126½ miles, and my impression is that the new line was to shorten this—instead of which, it appears to make it 16 miles further.

In my letter (24478, p. 429) there is a slight misprint, occurring in the last line, where "lat." should be "est." **W. S. Franks.**

## 100 TO THE INCH.

[24506.]—I AM inclined to be rather sceptical about the high powers said to have been used with advantage on telescopes in former times. Probably the observers were not very careful in verifying the nominal powers of their eyepieces. Browning, in his "Plea," mentions having a telescope brought to him with an eyepiece engraved 70, which only magnified 13 diameters, and my own experience leads me to believe that the powers marked on eyepieces are generally more or less exaggerated. It seems easy to find the power by dividing the diameter of the object-glass or mirror by that of the bright spot seen at the eyepiece, but it is very different to measure the diameter of this spot. The dynameters of the Berthon type are of little use, unless the straight-edges are absolutely true, and this, I fear, is seldom the case with the instruments generally sold. I have tried four, with most discordant results, one making the high powers nearly double what another made them. Moreover, the screw for the dark head keeps the dynameter some little distance from the eye lens, and this renders it difficult to be quite certain that the diameter of the spot is accurately measured. I believe that the power can only be accurately measured by the use of an instrument made on the principle of a micrometer, and unless we have good evidence that the powers which Kitchener and others are said to have used were measured in this way, we may well believe it more likely that the powers were much lower than stated, than that their telescopes were so far superior to modern ones as to bear 300 or more to the inch, even in the steadiest air.

I have seen it stated that at least about 35 to the inch is required to show star discs. From this it would appear that large apertures would scarcely ever show them, as 35 to the inch on 30 inches would mean a power of upwards of 1,000. I should be glad to know the experience of those who have worked with large apertures. **T. Perkins, M.A.**

## ERRATUM.—PAIR NEAR δ CEPHEI—VEGA.—70 OPHIUCHI.

[24507.]—IN letter 24474, *for* Bode (Lalande 28500) *read* Coronæ 26 Bode (Lalande 28500.)

The triple near δ Cephei, referred to by "H. D." (letter 24479, page 429) is evidently ♅. iv. 31. Through some strange oversight I have identified this with O.Σ. 473 in my Notes and Corrections to ♅. ♅ says of it, "Treble, the nearest about 20″." The principal star is Arg. (+ 57°) 2542, 8·3 mag., 45 seconds of time exactly *p.* δ. I see I examined it in 1881, and identified it with ♅'s triple then; but I will look it up again on the next opportunity. It has never been measured.

If "H. D." will do me the honour to refer to a note of mine in the ENGLISH MECHANIC for Oct. 19, 1883, he will see that I there refer to the most distant (misprinted "distinct" in letter 21924) companion of Vega at 40° 140″ ± as being probably variable, as well as the nearer *comes*. In October, 1870, it was a full magnitude fainter than the nearer *comes*, which Dembowski has measured less than a quarter of an hour after sunset with 7½in. I am obliged to Mr. Franks for the date of his observation of the colours of the components of 70 Ophiuchi in 1876. De. saw them "gialla, rosea; bene." 1876·566, 1876·613. **H. Sadler.**

## THE DOUBLE TELESCOPE.

[24508.]—I AM able to report some progress in following up the suggestion of "W.T.N." (23850), page 539, Feb. 20th, to bisect a large object-glass and mount the halves binocularly. Opticians in Paris divided a 2in. lens, and found the two sections to give the desired results. I have, consequently entrusted them with an 8in. object-glass to divide into two, and mount for me in a 12in. tube of 8ft. focal length, to be furnished with the three movements for the independent adjustment of o.g. and e.p.'s, as already fully described in the account of my 5ft. binocular (23670), page 368, on Dec. 26th, 1884, of 3⅜in. object-glasses.

This will, of course, take some time to accomplish, and, in the interval, I hope to elicit from our readers all improvements which may occur to them on the following device for making a perfect stand for binoculars.

The suggestion of the observing floor being constructed on the equatorial plane was thought too cumbrous. Mr. H. Ritchie's counter proposal and sketch (24228), May 15th, is, he will see, not equatorial, but only an inclined stand, with alt.-az. motions. I have not, however, been able to find a flaw in the following—viz., the "Philip Vallance" stand with an equatorial motion. I start with his centre tube firmly attached to base; within it, the second tube revolving on pivot point at bottom, and within brass bearings at top, ending in the T-piece, through which runs a third tube some 24in. long, on to each end of which I propose to screw (and make fast with bolt and nut) a 3-socket piece, one socket to screw on the end of the 24in. tube, one to receive A, a 6ft. horizontal tube, and the third to receive B, a 3ft. vertical one, which, having a right-angle socket at end to carry a 3ft. tube C, at right angles to B, completes the Vallance stand as applicable to binoculars.

The two horizontal tubes, A, suitably fastened together at intervals, will form a ladder-shaped cradle, on which the 12in. tube will be fastened with a sliding attachment. The two other horizontal tubes, C, will carry two counterweights, aggregating a few ounces less than the binocular plus its cradle.

The object in raising the counterweight tubes C 3ft. above the level of the cradle by means of the upright B tubes, is to keep them clear out of the way of the observer, who will sit at the eye end of the cradle with the centre pillar tube between his knees, thereby insuring the unvarying position of the eyepieces and of the observer, whatever direction the telescope may be pointed to.

The binocular will slide on its cradle, in order to preserve that unaltered position of the observer when used terrestrially, which will lengthen the instrument from 8ft. to 9ft. 6in. The counterweights will be also adjustable on their tubes C, with rack and pinion to correspond with the increase of weight incurred by the terrestrial position of the telescope.

This completes the description of the stand, leaving the telescope a few ounces heavier than its counterpoises, and resting on a section of a circle in metal, with a rise and fall motion by rack and pinion, attached to a stout pillar about 2ft. from, and fastened to, the centre tube.

Now comes the equatorial idea: the revolving tube has a toothed circle attached to it, moving instrument in az.; one single fixed rod, with a convenient wooden handle in the centre of it, has an endless screw at the observer's end of it which gives the movement in az.; it has also a toothed pinion at the other end of it, which *at the same time* gives the movement in alt., by raising the metal section of a circle on which the telescope rests. And if the sizes of the two wheels which are revolved by the one fixed pinion rod are calculated of the relative sizes proportionately, which alt. and az. motions bear to each other in the composition of equatorial movement, I ought to produce equatorial motion by clamping the two actions together, and alt. and az. motions respectively by ungearing them. The telescope cradle must of course run on a small wheel where it rests on the supporting metal circle-section, to facilitate the application of the az. motion simultaneously with the alt.

Perhaps our "F.R.A.S." would kindly tell me the relative proportions of alt. to az., say, in number of teeth in each wheel to produce equatorial results, and at the same time inform me of difference of teeth needful for change wheel to gear for lunar vice sidereal rate, if both are desired to be attained from the use of the same driving clock. **Montmartre.**

## SHORT-FOCUS REFLECTORS.

[24509.]—IN answer to "B. R. W." (24499), I may just say that that proportion of focal length to diameter of mirror is the best that gives the best balance of advantages with least disadvantage for the object for which the telescope is intended to be used. A short focus has the disadvantage of requiring a larger flat, and thus the loss of more of the best part of the mirror, and of light, too, as well as requiring a higher power eyepiece to get the power the amount of light will bear. Its great advantage lies in its shortness, which allows more convenience in using and less cost in mounting, and if in an observatory less cost for building. Now, these disadvantages and advantages each observer must find out the balance that for his purpose and means is the best in his estimation. I have often thought over this subject, and could only wish the Cassegrain could be made as perfect as the Newtonian, and then with a flat interposed between the two mirrors to throw the image to the side of the tube at its lower end we could get a very short telescope, which would require very much less for mounting and observatory than for a Newtonian of equal power and light. This saving could be employed in getting a larger Cassegrain and observatory than a Newtonian and observatory for the same money.

I believe, for Newtonians, eight diameters is best for small mirrors—say, up to 12in.—and seven diameters, or a little under, for larger mirrors, which can be better used on nebula where light is the great desideratum. This is, of course, only my opinion of what, for me, is the best balance of the advantages with the disadvantages of longer and shorter telescopes.

"B. R. W." says he finds no difficulty in parabolising a 5in. mirror of only 25in. focus. I hope his judgment of the figure of his 5in. is dependent on something more than a trial of it in the telescope tube with an eyepiece. By this means he cannot be sure that every zone is of the right focus or curve to form with all the others a true parabola. Even tested zonally in the telescope only a comparatively rough estimate can be formed of the focus and figure of each zone, and the figure as a whole. The zonal test at so-called centre of curvature is at least four times as exact, besides giving the figure of each part of the zone. If he would like to have it tested, I will do it for him with pleasure; it will only cost him the carriage to and from me, and then he will know exactly what he has done. But I hope he has mastered the zonal and shadow test for himself; it is an immense advantage to every worker of mirrors.

I am glad the Cassegrain has fallen into two such good hands as Dr. Pigott and Mr. W. Bradbury; we shall have all that is at present known about it, which will, I hope, lead to some improvement. I am sincerely glad that the illness in the doctor's house has so far abated as to allow him to resume this interesting subject. **H. A. Wassell.**

Addenbrook-villa, Love-lane, Stourbridge.

## THE CASSEGRAIN.

[24510.]—I WAS indeed sorry to see by his letter in to-day's "E.M." that illness in his family had been the real cause of the interruption in Dr. Royston-Pigott's interesting letters. Now that he has returned to the subject, I trust he will do for the telescope what he formerly did for the microscope in making it proclaim its own defects, and thus indicate the path of progress towards perfection.

If the mathematicians will give the means of determining the aberration measurements at centre of curvature for the figure that should be given to the great mirror, Mr. Wassell's method of testing would soon settle the matter as regards its accuracy, and then there would seem no great difficulty in working a truly spherical small mirror to match it.

I fear it is of no great value practically, but I would throw out the suggestion that it might be possible to work and test the small mirror (especially the convex of a Cassegrain) as a lens before silvering it. As Dr. R.-P. has doubtless observed, there are several printer's errors in his letters which rather obscure his meaning at times. **A. S. L.**

## BINOCULARS.

[24511.]—I CAN hardly agree with "Montmartre" that "two eyes see more than twice what the single eye sees." When you shut one eye you see just as well as regards definition and illumination as if you were using both. A one-eyed man sees every whit as well as a man with two. In the same way, an object-glass does not feel any warmer or colder by touching it with two hands instead of one. So much for the $A + A$; now about the $x$. There is a distinct advantage gained by two eyes when viewing near objects, because of the stereoscopic effect; but when objects are a few yards off there is no difference, whether one or two eyes are used. Binocular, Galilean, and twin telescopes restore the stereoscopic effect, whatever the distance. Example: the moon, with one eye, without optical aid, appears the same as the moon with two eyes; but look at it with a binocular instrument, and it will appear as spherical as an orange on a table before you.

There is another quantity which has been overlooked by "Montmartre"—viz., a term to represent that imperfection of definition which is inseparable from the Galilean telescope; this we may call $y$.

I am quite ready to allow $A + x - y$, but cannot admit $2\ A + x$. The whole question turns on whether $x >$ or $< y$. If $x > y$, then a binocular has a pull over a telescope; but if $< y$, then the reverse is the case. It is to a great extent a matter of personal equation, therefore everyone must put in values for $x$ and $y$ for themselves, and draw their own conclusions.

Testing eyepiece diaphragms.—The diminished image being at the eyepiece end will not alter the results. If the diaphragm in the erector is too small, the blue patch will come over the disc all the same. If you wish to get rid of the diminished image, hold the telescope up to the sky.

The field of my 2⅛ binoculars is 2°. They are aluminium, of French manufacture, with a Bond-street name on them, and cost £17. I bought a similar pair in brass, ten years ago, abroad, at a reasonable price. The name on them was Ch. Avizard à Paris.

Shetland, July 13. **Edward M. Nelson.**

## DYNAMO MACHINERY.

[24512.]—MR. J. SUTCLIFFE (letter 24469) will find that Professor Thompson's calculation is correct under certain conditions, which are fully specified in his book.

The horse-power produced in a dynamo is well known to be expressed by—

$$\frac{EC}{746} \text{ (E in volts, C in amperes.)}$$

Thus H.P. of large dynamo is to h.p. of small dynamo, as $EC$ is to $ec$, using small letters when referring to small dynamo.

Now, $E$ is to $e$ as the number of magnetic lines of force cut by the revolving coils of the large dynamo is to the number cut by the revolving coils of the small dynamo in the same time, and if we make the large armature revolve as many times per second as the small, we shall have—

$$E : e :: N : n$$

where $N$ and $n$ are the total number of lines passing between the poles in the large and small machines respectively.

What is the relation between $N$ and $n$?

First, suppose the magnets are independently magnetised, and let the magnetising current be supplied from the same battery in both cases; then the current through the larger coils will be twice that through the smaller, and this will produce an equal intensity of magnetisation in both large and small magnets; whence, since the cross section of the larger core is four times that of the smaller, $N$ will $= 4n$, and therefore $E = 4e$. This, again, will make $C = 8c$, and $Ec = 4e \times 8c = 32ec$, whence H.P. : h.p. :: 32 : 1.

We have supposed all the linear dimensions of the large dynamo to be double those of the small dynamo, and therefore the resistance of the large coils to be half that of the small coils.

This result can hardly be looked for in practice unless special arrangements are made to render the large magnets more susceptible to magnetisation than they would be if of the same construction as the small magnets.

Other arrangements may be adopted with the same result, the fundamental requirement being that the larger magnets shall be magnetised with the same intensity all through as the smaller magnets. If the dynamos be both shunt-wound, the desired effect may be obtained by winding the large magnets with the same gauge of wire as the smaller and with the same number of layers; the resistance of the larger coils will then be four times that of the smaller, and if $E = 4e$ the same current will run through both coils, and this will produce the same intensity of magnetisation in both magnets. As we have seen, the E.M.F. thus produced will be $E = 4e$, and will, therefore, be just sufficient to keep up the required current, and the arrangement will therefore continue to work.

In this case the H.P. wasted in the larger coils is only four times that wasted in the smaller, while the total H.P. produced in the larger dynamo is 32 times that produced in the smaller.

In the former case, the H.P. required from the battery which magnetises the large magnets is only twice that required from the battery which magnetises the small magnets. Hence, in both arrangements, the larger machine scores heavily in that respect.

M. Marcel Deprez compares the large and small machines under a different set of conditions. He requires that in both machines the current shall be the same per square centimètre of cross section of the conductors. That is, $C = 4c$, and if we produce in the large magnets twice the intensity of magnetisation produced in the small magnets, we shall, by similar reasoning, obtain $E = 8e$, and

$$\text{H.P.} : h.p. :: 8e \times 4c : ec$$
$$:: 32 : 1.$$

In this arrangement the total resistance of the main circuit, including the armature, must, in the large machine, be twice that of the corresponding circuit in the small machine.

Mr. Sutcliffe seems to have satisfied himself that the statical attraction is increased in the ratio of 16 to 1. It follows immediately that since all distances are doubled in the larger machine, the distance through which the larger attraction acts is twice the distance through which the smaller attraction acts, and thus we get the ratio of *work done* to be 32 to 1.

Clevedon. **W. M. M.**

## EDER'S DEVELOPER.

[24513.]—IN your No. 1,060, under "Experiments with Gelatine Emulsions," a very important error appears, which calls for instant rectification. You give Eder's admirable formula for development as—I. Pyro. 10, sulphite amm., 30, water 100. II. Brom. amm. 5, water 150. II. should be instead: Brom. amm. 5, ammonia (·880) 50, water 150.

In your formula the ammonia has been omitted, and anyone trying it, then, would naturally get no picture at all.

This developer is quite admirable, producing very soft yet vigorous pictures at will, and appears to work equally well with every make of plate, and with Morgan and Kidd's negative paper.

British Legation, Darmstadt. **N. Jocelyn.**

## PYROLOGY.

[24514.]—YOUR readers will welcome the reappearance of Mr. A. H. Allen in the columns of the ENGLISH MECHANIC, and none more than myself, although his first revived contribution appears to contain an unfavourable critique on my own work. Mr. Allen generally remembers what some modern English chemists seem to forget, or rather, not to be aware of—viz., that society expects them to show by their polemical writings that they are gentlemen as well as chemists: his chemical criticisms, therefore, usually exhibit the (in England) peculiar anomaly of being courteous as well as laboratorical.

If Mr. Allen's logic and acquaintance with his present subject (the heading of this letter) were only equal to his knowledge of chemistry and courtesy, he would doubtless prove a formidable antagonist, if, in that event, he remained an antagonist at all; but as nothing is more painful to me than giving a direct contradiction in print to the statements of so polished a chemist as Mr. Allen, I wish that in his future publications he would pay more attention to the truth of his premises before allowing his chemical zeal to hurry him to such rash and wrong conclusions. For, I am sorry to tell him that, in my portion of his contribution to the "E. M." (page 45[illegible]) the first position, which he assumes as a well-known fact, and thereupon bases his entire argument, is so false and exactly opposed to the truth, as to appear (for a man of his sagacity) in the last degree childish and absurd. He assumes that accuracy of analysis is in inverse proportion to the minuteness of results revealed, and states *ex cathedrâ chemicâ* (let us hope he is only speaking for Yorkshire or Sheffield, and not for England, Germany, and America here) that "chemists cannot direct their serious attention to the matter"—*amoto quæramus seria ludo*—"unless the subject of analysis is operated on in reasonably large quantities."

Now, it is surprising to find a clever and, generally speaking, well-informed man so far behind the information of his own time as not to know what the microscope and spectroscope (not to mention the blowpipe) have long since shown us, that extreme accuracy in the estimation of the nature of a compound is only compatible, and in a direct ratio, with the minuteness of the revelation of constituents. But why should Mr. Allen draw the line at a platinum crucible full of material in his definition of "a reasonably large quantity"? Other operators, working in a different line from Mr. Allen, might call this quantity unreasonably small. The distiller would say: "Operate on a bucketful if you want to have a correct knowledge of the subject." The smelter would contend that "you could do nothing with less than a ton of material."

On the other hand, the rapidity of results obtainable with the blowpipe enables the operator to confirm or displace the revelations of his first analysis by those of half a dozen others in a not fatiguingly long space of time, and even Mr. Allen will scarcely assert that if you obtain the same weight of result in your assay balance by six different analyses of the same materials, you have not reasonable ground for concluding that result to be correct.

I have, far more than six times, found quicklime to combine with boron trioxide (or anhydrous boric acid) before the blowpipe, to form calcium pyroborate in the invariable proportions of 25 per cent. of the former to 75 per cent. of the latter; yet Mr. Allen reiterates the absurd objection that this invariable result might be merely accidental. "You have not proved (says he) that some of the lime was not dispersed about the bead." If Mr. Allen had ever tried to perform this simple operation (for it takes far less time to perform than to write long-winded letters about) himself, he would have found that "You" *have* proved it—*ipso facto*—by the operation itself. For, if any lime were "dispersed about the bead," it would, in each or any of its localities, form calcium pyroborate in that locality before the blowpipe, and as such be at once discovered as a ball with the lens, capable of being boiled out and weighed with the rest of the calcium borate; but he would be a very clumsy operator with the blowpipe who could allow such a *contretemps* to take place, and a very foolish and untrustworthy one not to make a fresh analysis in that case, for separate lime-balls always coalesce into one, in a bead of boron trioxide, B.B.

But the fact is, this clever chemist has never tried these things practically himself, and therefore—to call a spade euphemistically—remains slightly unacquainted with the matter in hand, and should not, therefore write about it at all until he has removed this disadvantage. If Mr. Allen will go into the subject practically at his leisure, and start a small blowpipe apparatus in his laboratory—he is not far from Warrington, where he can get a first-class footblower from Mr. Fletcher—I will ask my publishers to send him a copy of my last little work for his guidance at first. It is really painful to see such a writer as Mr. Allen sliding into the ranks of those chemical boobies who presume to write and publish on a difficult subject, without any practical knowledge of it whatever, deeming "wet" methods of analysis, in which they are doubtless proficient, all-sufficient for everything else, however different. One never finds German, French, or American chemists doing this, and although I am not aware that they possess, like those English chemists of whom Mr. Allen speaks, any power of "attention" which is not "serious," some of the most celebrated have long ago "directed their serious attention" to this matter. Professor Bruno Kerl, of Berlin, has sent me original articles he has contributed to his own paper, the *Berg und Hüttenmännische Zeitung*, upon it, and Professor Cornwall, of New Jersey College, the well-known translator of Plattner's "Probirkunst," has written to tell me he has procured my last work on the blowpipe, and considers my system of anhydrous analysis worthy of his profound (and now being applied) attention. **W. A. Ross.**

## EXAMINATION OF MINERALS BEFORE THE BLOWPIPE.

[24515.]—No. 6 seems to be a soda feldspar, containing also potash. If there was no water, or very little, found in it, I should be apt to think the mineral what Des Cloizeaux, after the French mineralogists, calls "Schorl Blanc" or Albite; which is classed by Dana among the "unisilicates," and analysed (by Brooks) as follows:—$SiO_2$ 67·39, $Al_2O_3$ 19·24, Mg 0·61, CaO 0·31, $Na_2O$ 6·23, $K_2O$ 6·77 = 100·55.

No. 7, "An alkaline (soda) aluminous silicate," probably containing water, as the "icelike mass" contained in the boric acid bead, dissolved so rapidly before the blowpipe; in which case we should have to look for it in a mineralogy under the head of the soda-zeolites, probably analcite; but really, in the absence of all indications derived from crystalline form, and the presence or absence of water, it is hard to say where one should look for the particular species of such minerals. An analysis of "zeolite dure" (or hard zeolite) of Dolomieu—i.e., analcite—from Giant's Causeway, is $SiO_2$ 55·60, $Al_2O_3$ 23·00, $Na_2O$ 14·65, $H_2O$ 7·90 = 101·15 (Thomson).

No. 8 I should say was Heulandite (?), which has a peculiar "shade of white passing into red" colour, and a hardness of only 3·5; but it again has a large percentage of water and a considerable amount of lime, neither of which are mentioned by Colonel Ross: $SiO_2$ 59·64, $Al_2O_3$ 16·33, CaO 7·44, $Na_2O$ 1·16, $K_2O$ 0·74, $H_2O$ 14·33 = 99·64 (Damour).

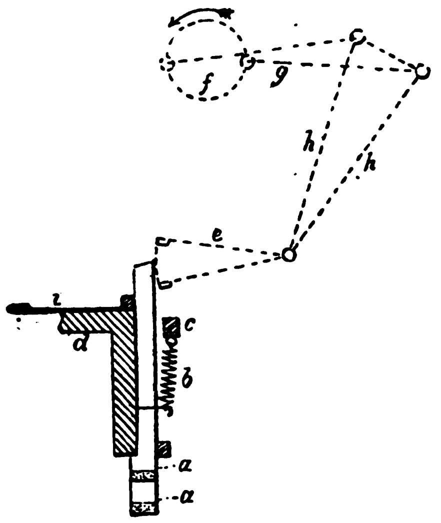
No 9. "A crystalline-fibrous, soft, white, opaque, soda-alumina silicate, with between 10 and 20 per cent. of soda, a considerable proportion of alumina, and a trace of lime." This description appears to me to tally almost exactly with that of "Natrolite": $SiO_2$ 47·76, $Al_2O_3$ 25·88, $Na_2O$ 16·21, $H_2O$ 9·31 (Fuchs).

No. 10. "A phosphate of iron, with a little manganese and lithia, and a trace of soda." Looking in Dana, under the head of "Anhydrous Phosphates" for an iron phosphate with lithia (I should think a solution of this mineral useful medicinally), I came across the very one, "Triphylite," page 541. Analysis by Fuchs: $P_2O_5$ 41·47, FeO 48·57, MnO 4·70, LiO 3·40, $SiO_2$ 0·53, $H_2O$ 0 68 = 99·35.

**Mineralogist.**

## AUTOMATIC MUSICAL INSTRUMENTS.

[24516.]—I GIVE an outline diagram of the movement of my pianoforte player reduced to half size. Further particulars are shown in the specification, No. 5024, 1884. A A are the plungers, long and short, to suit the raised keys, placed in a row; they are wooden rods, square in plan, with pads of thick felt at the base, which projects backwards for a stop to limit the rise in the sockets. They are drawn upwards, clear of the piano key, by coiled springs of very thin silver wire, *b* (008), attached to the plungers, and the fixed rail, *c*, above. As the pull is out of the centre, the plungers are thrown back against the base-board, *d*, so lightly that the mere force of the breath passed along the tops is sufficient to deflect them against the stop-rail, *c*, and, being caught by the vibrator, the notes are sounded in succession. This is all the work that the music bands have to do, and consequently the paper is free from strain in sounding the notes. The dotted lines represent the path of the vibrator and crank movement. *e* is that of the vibrator or finger piece, consisting of a wedge-shaped strip of mahogany, 3ft. 4½in. long, extending backwards over all the plungers. It is armed with a strip of felt under the thin front edge, at which the tops of the plungers are caught. The circle *f* is the path of the crank-pin, situated mid-way over the length of the vibrator, *e*; *g* is the connecting rod; *h* is the arm or lever, from *e* to *g*, made of a blade of elastic steel, so as to yield slightly when a note is struck. It will be seen by the diagram of the angle lever-motion that during the sounding or down stroke the crank pin recedes from, and in the up-stroke approaches to, fulcrum of *e*, so that the speed of this is increased during the rise, giving what is known as a "quick return" to the vibrator. The crank spindle makes 600 revolutions per minute. This exceeds the shortest interval between the notes in musical composition, and the very quickest passages are rendered with clearness and accuracy. *i* is the thrusting wire. The pulling wires running the length of the base-board are of annealed copper, No. 21, passing at intervals under guides or bridges, so that the instrument can be carried in any position without derangement.



The width of my music bands is 9½in.; there are 75 keys or notes, spaced ⅛in. asunder. The length of the instrument is 3ft. 9in.; width of the box, 11in.; depth, 4in. The total weight is 24lb., so that it may be easily carried about.

In reply to "Vulcanite," I have to state that, although my vibrator is something similar in action to that of the "Organo piano" of Metzler and Co., yet the intention and effect are different. The beautiful sustained tones of their instrument are produced by the vibrator acting directly on the strings and making about 1,500 strokes per minute, giving a continuous sound. In mine there is a distinct repetition of sounds.

I have also to inform "A. S. L." that I abandoned the use of skew or silent gear for driving my crank spindle, for, however well made, some noise from the rubbing of the teeth occurred; I therefore use a gut band in the same way that it is adapted in some watchmaker's bench or hand lathes —viz., with the driving axle at right angles to the mandrel, and as my instrument is almost frictionless, and the power required to turn the handle is scarcely felt, a small gut suffices; this is only ·06in. in diameter, and is ever-enduring.

I should have stated that in Prof. Gally's "Orchestrone" although the circular holes in the paper music band are only $\frac{1}{10}$in. in diameter, in long-sustained notes or line, they are placed in a series very close together, and the "wind" is drawn through two at the same time, so that the reed orifices are not closed during the note. This leaves cross-ties between the slit in the paper, which would otherwise, for the sustained tones of organ music, be cut nearly into ribands and materially weakened.

**F. H. Wenham.**

[24517.]—I AM much vexed that Mr. Ray should have been troubled by "Gray's-Inn" in connnection with information courteously given to myself in the course of private correspondence, nor did I think "Gray's-Inn" was justified in taking such a step, even though the result has been to confirm my own statement.

I do not propose to follow all the fanciful names, and changes of names, subsequently adopted by the dealers in these instruments; but as the organette, as originally imported by Mr. Ray, had levers, and in the orguinette, as imported by Metzler and Co., had none, I have always used (and shall continue to use) these names as conveniently distinctive of the two classes of instruments. In reality, the late Mr. Croger gave the name of organette to a miniature harmonium long before the date of the automatic reed instruments.

Would it not be better if "Gray's Inn" were to send to (or induce Mr. Fryer to send up) a working drawing of the lever instrument in question, instead of "squabbling" about the name by which he thinks it ought to be called, and continually carping at me who am simply endeavouring to give practical information to those who have asked for it.

I fail to understand the remark about the large circulation of the "E.M." I myself have read it in places many thousands of miles from 332, Strand; but what has that got to do with the question of "levers or no levers" in an organette?

**A. S. L.**

[24518.]—HAVING recently noticed a revival of the subject of automatic musical instruments in "Ours," I beg leave to correct "A. S. L.," page 365, with regard to the non-fulfilment of my promise of sending instructions how to make one of the above-named instruments. My intention was not to send a sketch of the mechanism of the "organette," as "A. S. L." seems to imagine on page 365, but to furnish instructions how to make an automatic musical instrument to contain three chromatic octaves (37 notes or reeds). This would be the smallest compass that could be allowed in order to produce an unlimited number of melodies of various strains and character, with a certain limited amount of harmonious accompaniment, which could be varied in character, like that of the melody, as far as the limited compass of notes employed would allow. There is one thing in connection with automatic musical instruments that requires improvement, and that is to lessen the grinding character of the music produced from them. In those instruments in which the paper strips are employed the notes do not sound prompt enough, and in those instruments which have levers the notes appear to be cut too short by the irregularity of the action of the pallets, which soon makes itself manifest after the instrument has been used much. I could better explain my meaning by the agency of a diagram. "A. S. L." does not seem to have properly studied the mechanical arrangements of the various classes of automatic musical instruments; but his knowledge of cutting out the holes in the paper bands or strips I think may be said to be perfect, as I must give him credit for being one of the most competent writers in "Ours" on the making of paper bands. Our friend Mr. Wenham goes further into the subject, and explains some matters in connection with the higher and better class of automatic musical instruments. If that gentleman could find time to explain how to make a simple automatic musical instrument that could be constructed without any particular or elaborate ingenuity, I think it would interest a large portion of the readers of "Ours." If I sent instructions for making one, I should merely describe the mechanical arrangements, but should not attempt to instruct readers on the making of perforated bands or discs. The latter is a subject which, up to the present time, appears to me somewhat incomprehensible, in consequence, I suppose, through my loss of interest in that matter. I am nevertheless always willing to help any of "Ours" in any way I possibly can.

In reference to the letter of "Gray's Inn," p. 433, that gentleman is quite correct in stating that "orguinettes" and "organettes" are practically identical, which means, I presume, that they are similarly constructed. There is a little instrument made, which is called the "organina," constructed with levers, which are actuated by the employment of perforated paper strips or bands. The music produced from this little instrument is superior to that of the organette, as the notes speak promptly, and are minus of that drony speech so prominent in the action of the organette.

**G. Fryer.**

## GLASS DISCS FOR SPECULA.

[24519.]—I AM not able at present to give Mr. Wigmore, of Melbourne, any further information on the above, except to say that Messrs. Chance, in their reply to me, express their willingness to communicate direct with Mr. W. if he will write to them. I believe there is no parcel post with Australia, and a 9in. disc would weigh considerably more than the present limit in use in this country. I am told the charges for freight are principally based upon the cubical content of the packages. I should think it would not be very high, and Mr. W. might inquire of the shipping agents at Melbourne.

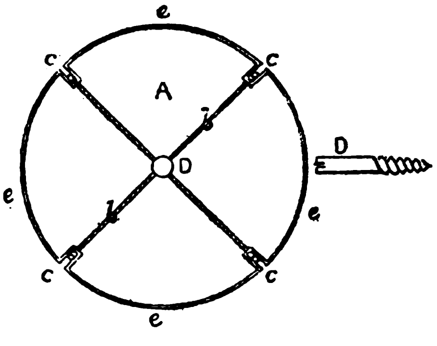
**J. C. L.**

## POLISHING OR GRINDING WHEEL.

[24520.]—I INCLOSE drawing of a grinding and polishing wheel, easily made and kept in order.

A, a wooden disc mounted on a commen wood screw, D, whose head has been sawn off or turned down. The disc secured firmly in this can be mounted in a concentric chuck in the lathe.

Being turned true, three or four saw kerfs, *c*, *c*, *c*, are cut into its edge. Strips of Canton flannel, woollen flannel, cloth, or buckskin, *e*, are wrapped around the circumference of the disc, and tied tight by cords, *b*, *b*, *b*, *b*.



Charge the cloth with rouge, rottenstone, putty, or use emery cloth or sandpaper. The faster it moves the more effective and rapid the work. The clothing can be removed and others substituted.

**M.**

## SPURIOUS BUTTER.

[24521.]—IN a recent number of our "E. M." a method is shown of detecting adulteration of butter by observing the colour produced in true and spurious butter on the addition of sulphuric acid; but though a less valuable test, still deserving of attention as being rough and ready and easy of application, is to grease a piece of paper with true and suspected butters. Roll the papers up, and set them on fire. The smell of the pure butter is pleasant, that of butterine has distinctly a tallowy smell, quite easily to distinguish from the honest article. I would earnestly urge on my friends to have nothing to do with spurious butter; the probability is that it is made up with mixtures of fat which are full of germs of tapeworm and trichina. The genuine article is now cheap enough; insist on having it—only it.

**E. B. Fennessy.**

## OVERFLOW IN WATER-WASTE PREVENTER.

[24522.]—IN 56404, No. 1015, I described a cure for the above trouble by forcing down the feed ball-cock so as to lower the level of the water supply to the W. W. P. by half an inch. I deceived our readers and myself. After two months' obedience to the treatment the troubles recommenced spontaneously.

On examination, it was found the obstinate ball-cock—taking "Resurgam" for its motto—had regained the mischievous level, and was causing an overflow in all directions beyond the ability of the waste and warning pipe to deal with.

I thereupon procured a copy of Mr. Davies' new work on "Plumbing," recently advertised in "our" columns; but though I found most ample descriptions of varieties of W. W. preventers, with diagrams of same, including the identical offender, I could meet with no instructions for regulating the ball-cock anywhere. I therefore wedged a piece of wood firmly between the iron sides of the W. W. P. directly over the ball of the ball-cock, at such a height as will preclude the water level ever rising to within ⅜th of an inch of the overflow. As this is an item which affects every water company, as well as every householder, W. W. P.'s being now a necessity by Act of Parliament, proper provision should be devised and promulgated to remedy this defect.

Since writing the above, I see that Mr. Davies had kindly advised on the case on p. 239; but neither of his two suggestions meet the circumstances. **Montmartre.**

### ORGAN DESIGNING.

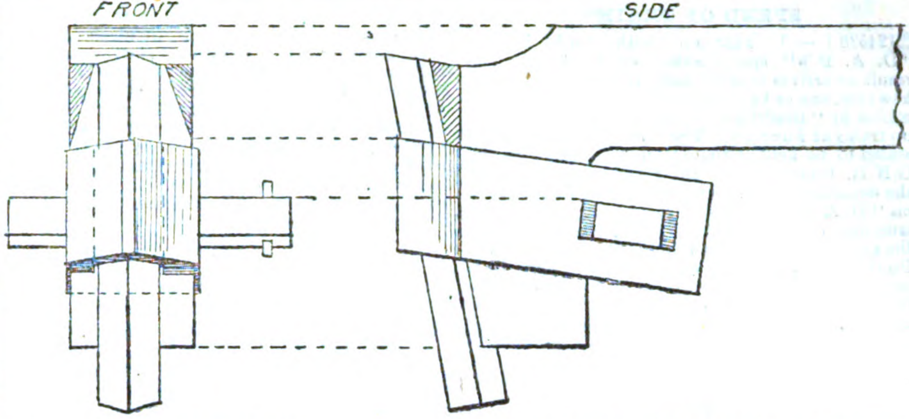
[24523 ]—Amongst the various registers which go to make up the contents of an organ, one always finds a number of stops which are never drawn singly, and which, moreover, are always drawn in certain combinations. Amongst those registers of more acute pitch, such as furniture, cymbals, &c., this principle is always recognised, and three or more ranks of pipes placed under the control of one stop handle.

But there are, in addition to these, stops of the mutation class 5⅓ft., 2⅔ft., 3⅕ft. &c., and stops of 4ft. and 2ft. pitch which are never used singly. And what I want to know is, Would it not simplify the work of an organist immensely to have all such registers as these under easier control than at present? For instance, on the great, one never uses the principal without the open, nor the twelfth without both fifteenth and principal. What I suggest would apply chiefly to those large instruments wherein fifty or more stop handles confront the player, on not more than twenty of which perhaps he ever lays his hands, all the rest coming out in groups under the direction of composition pedals or pneumatic pistons. Let there be on the great organ a stop containing ranks of pipes of 8ft., 4ft., 2⅔ft., and 2ft., and if there be an open 16ft., insert a 3⅕ft. rank. The same will apply to the swell and the pedals, and in this way no less than four useless stop handles in each organ will be eliminated. As it is just possible that in the swell a 2ft. may be used for special effect, a wooden stop of that pitch might be added. In this way an instrument with thirty-six visible stop handles would have as many pipes perhaps as one of sixty, and there would be far less to perplex a strange organist. Of course, by many people the size of the instrument is gauged by the number of stops without any reference to the number of pipes, and thus it comes to pass that builders desirous of making a "thin" specification as imposing as possible, will split a V.-rank sesquialtera into two of II. and III. ranks, and divide the double into Tenoroon and Bourdon; also have a stopt diapason Bass and "clarionet flute" treble, and put in a number of stops such as tierce and twenty-second, which ought properly to be contained in a mixture. I only know of two organs where the method I have indicated is carried out—viz., in the pedal of the large instrument at Boston, U.S., and at in the great organ at Edinburgh University, N.B., or the Edinburgh Music Hall, I forget which, there is a harmonic mixture of XIV. ranks, beginning at 8ft. It used to stand on the soundboard of the solo till the latter was inserted. This principle of combination might be carried still further if it is remembered that in the pedal the 32ft. never are drawn without the unisons, nor in the manuals the 16ft. without the 8ft.

Perhaps someone will say if the large organ by Cavaillé-Coll in St. Peter's, Rome, is yet opened, the specification of which was given in these pages some years age. **John T. Lawrence, B.A.**

### ELECTRICITY IN MACHINE ROOMS.

[24524.]—Electricity is sometimes very troublesome in machine rooms, where the belts and other parts run at high speed, and especially so in dry weather, when there is little moisture in the air: temperature seems to have little influence. A friend writes me that in his shops last January, the saws, planers, &c., in the pattern-room became heavily charged with electricity, which at times developed great intensity, and rendered working the machines quite unpleasant, if not dangerons. The pattern-room is in the second story, and as live steam is used for heating, the floor was dry as tinder, insulating the machines as completely as if they stood on a glass plate. The frictional electricity from the belts charged the machines so heavily, that sparks ½in. long could be obtained by presenting the knuckle. To overcome the difficulty, a small wire was driven into a crack in the floor and connected to each of the machines, and to the water pipes, thus allowing the electricity to pass off gradually without acquiring intensity. This plan was perfectly successful, and can be applied in a few minutes. **E. A. M.**



### CUTTER-BAR.

[24525.]—I have read with much pleasure the letters of "O. J. L." on cutter bars, &c., in the "E. M." I herewith send drawing of one I have had in use for some time. If you should think it worth engraving and publishing, please do so, as I should like to have opinions upon it. I will not now speak of any advantages it possesses over those now in use, as I think the drawing will explain itself. I may just add that I use various sections of steel for tools in different bars, and that in my hands the bar is very satisfactory.

**G. Cordon.**

### NEW TRAINS, &c.

[24526.]—The companies' working time tables and those offered to the public differ in many ways, and though I am not in possession of this month's N.E.R. official time tables, I conclude that they grant an extra stop between Newcastle and Edinburgh for water, as was, I believe, the case with the up Limited Mail of the G.W.R. as it ran a year or two ago. According to Bradshaw, it ran without stop from Bath to Paddington (106¾ m.) in five minutes under the three hours. Again, during 1882, the up Highland express by the West Coast Route was timed on Sunday mornings to run continuously from Crewe to Willesden (152½ m.) on all published bills, but, I believe, it always stopped at Rugby.

The above suggests a query concerning that historical train journey from New York to San Francisco in 3½ days, performed, as far as I recollect, in 1876. A pictorial account of the trip in the *Illustrated London News* of the period states that the longest piece of continuous running was 444 miles! Did they couple two or three extra tenders to the engine or engines that drew the train, and so convey the necessary water and fuel?

In answer to J. T. Lawrence, I may say that several Compounds and Precedents are now in regular running from Crewe to Euston and back in the same day, and *vice versâ*; but the L.N.W. engine, doing the largest daily mileage, and, I should say, also the hardest worked loco. on any line, is No. 955, Charles Dickens. She is a 6½-foot Precendent, and bears the date Feb., 1882. Since first put on she has regularly worked the same trains, going from Manchester to London and back in the same day. She takes the 7.45 out of London-road, arriving in town at 12.10 noon, and returns at 4 p.m. with the 4¼ hours express. Both trains run *viâ* Colwich and the Potteries, making two journeys of 182½ miles, which, with 5 miles of shed to platform runs, brings her daily total to 370 miles. As this engine goes out every week-day, I understand that alternate sets of men work her, and all turning up of wheels and slight repairs are done at Longsight on Sunday.

That typically competitive service between London and Manchester has once more been "improved and revised" by the three catering companies; the prayer of a Midland shareholder at a recent meeting for a uniform and non-competing service by all three routes in 5 hours has been disregarded; and, though last year's minimum time of 4¼ hours has not been surpassed, the number of trains completing the journey in that time has been more than doubled. The North-Western has been the first to quicken throughout this competition, because, having by far the shortest route, it has been, and is running, well within itself. Next year we may expect a further acceleration of a quarter of an hour, judging by the past.

Surely the "special expresses" of the G.N. and M.S. and L. companies cannot pay their way: six coaches and usually a dozen through passengers at a speed entailing extreme wear and tear of both rolling stock and permanent way does not seem like "good business."

The G.N. 5.15 a.m. Newspaper is better than "D. A. P." supposes; it is allowed (as "C. P." notes in the case of an up train) one minute at Finsbury, so that it should run to Peterboro' in 84 minutes, or 52⅔m.p.h.

Again, the 60 miles 24 chains between Northampton and Willesden in 70 minutes is the work of an up Manchester express on Sundays—viz., that due into Euston at 4.30 p.m.

Would it not be advisable for the G.N., on which steadiness of running appears to be decreasing in proportion to its present increases in speed, to take a hint from the North-Western and Midland, which have attained such smoothness of travel by means of radial and bogey carriages respectively?

It would interest many if one of our railway contributors would publish the working time table of the two new special mails between London and Scotland by the West Coast Route—*i.e.* the 8.30 p.m. ex Euston, and 4.10 a.m. in Euston. As neither carries passengers, no account of them appears in the public tables and time books. **L. N. W.**

### RAILWAY SIGNAL RETURNS.

[24527.]—Last week, p. 435, I gave a summary of the block system returns. The following table gives in detail the facts relating to the more important railways, from which it will be seen that some of the principal lines are in a satisfactory position:—

| Railway. | Total length of Line open for Passenger Traffic. | | Distance worked upon the Absolute Block System. | |
|---|---|---|---|---|
| | Double | Single | Double | Single |
| | Miles. | Miles. | Miles. | Miles. |
| Cheshire Lines, joint.. | 125 | — | 92 | — |
| Furness ...... | 72 | 34 | 71 | 34 |
| Gt. Eastern .. | 494 | 473 | 494 | 208 |
| Gt. Northern . | 570 | 169 | 556 | 91 |
| G.N. and G.E. joint... | 111 | 5 | 111 | 5 |
| Gt. Western .. | 1,041 | 988 | 889 | 753 |
| Lancashire and Yorkshire .. | 423 | 17 | 423 | 9 |
| L. and North-Western .. | 1,363 | 311 | 1,347 | 280 |
| L. & N.W. & G.W. joint.. | 111 | 27 | 111 | 16 |
| London and South-Wstrn | 523 | 225 | 523 | 200 |
| London, Brighton, and S.C. | 339 | 118 | 339 | 118 |

Hon. Mem. A.S R.S.

Assize Court, Manchester.

## SPEED OF TRAINS.

[24528.] — I PERUSED with much interest "D. A. P.'s" speed-table (letter 24487). The result he arrives at is certainly remarkable. I note, however, one or two errors. "D. A. P." has been misled by "Bradshaw" in taking the times of the up trains at Finsbury. The times there given are stated to be arrival times; but a reference to the G.N.R. time-bills will show that they are really the departure times. The run which stands No. 8 on "D. A. P.'s" list is No. 2 on mine (24489), the true time being 1.3, and not 1.5. Probably through the same error two runs between Peterborough and Finsbury, in 1.27 and 1.28 respectively, have been omitted, and also the 6.15 down express to Grantham in 2 6 = 50.24. Introducing these changes, and omitting the runs which are only made on certain days of the week, we get the following result:—

| Company. | Train miles daily at 50 miles per hour and upwards. |
|---|---|
| G.N.R. | 2,354 |
| L. and N.W.R. | 908¾ |
| M.R. | 606¾ |
| G.W.R. | 499½ |
| M.S. and L.R. | 360 |
| N.E.R. | 44¼ |

In other words, the G.N. runs very nearly as many miles at this speed as all the other lines in the kingdom put together. **C. P.**

## GAS LOCOMOTIVES.

[24529.]—"PROGRESS No. 3," on page 415, is, in my opinion, undoubtedly working in the right direction, inasmuch as he proposes to substitute gas for steam in the working of steam tramways and carriages. Unless, however, he proposes to dig holes in the road at every step with his pedal arrangement, I must confess I cannot see where the advantage over driving through the tire of a wheel comes in.

In any case, even when travelling at only a moderate speed, it would impart a very unpleasant jogging motion to the carriage.

I suppose he is aware that in the early days of the steam locomotive driving by means of feet was tried, also that it proved utterly unpractical.

If only we could get an efficient high-speed gas-engine, which would be light for the power it developed, the days of steam on tramways would be numbered. For it is obvious that no matter how much we reduce the weight of the *engine* in a steam loco., the boiler must always be the bulk of the dead weight to be carried.

Ashton-on-Mersey. **Stud. Inst. C.E.**

## THE TREATMENT OF BALDNESS.

[24530.]—FROM time to time queries and letters appear on baldness and its prevention; so perhaps the following from the pen of Dr. George H. Rohe, in the Atlanta *Medical and Surgical Journal*, may be acceptable:—

Having been himself a sufferer from seborhœa and consequent alopecia for six or seven years, the writer tried a great many remedies with a view to its alleviation and cure. Arsenic internally, stimulating washes or oily applications, containing in the one case corrosive sublimate, in the other quinine, or tannin, in still another some of the stimulating oils, were used with no appreciable effect either on the formation of scales or the depilation. Finally, about two years ago, an item went the round of the medical journals to the effect that a French physician had found that the local use of a 5 per cent. solution of chloral hydrate was a sovereign remedy for the trouble under consideration. Rejoiced that at last I could appropriately shout "Eureka!" I began to use the chloral wash assiduously for about three months, following the directions given as accurately as possible. At the end of the three months the production of scales was more rapid and the fall of hair greater than ever. Disgusted with the failure of all the therapeutic measures which had been so highly lauded, I almost decided to let the affection take its own course, and run the risk of a shiny bald pate at thirty. About that time the second volume of Hebra's classical treatise on diseases of the skin came to hand, and one of the first things I read was Kaposi's thorough article on alopecia. Impressed with the reasonableness of the views put forth by Kaposi, I determined to give his plan of treatment a trial, with the result of checking the fall of hair and diminishing the production of scales in a reasonably short space of time. I have since then recommended the plan in a considerable number of instances, and when it has been faithfully carried out with uniform success.

The success of the method depends upon the use of an agent which, while mildly stimulant, removes the scales and thoroughly cleanses the scalp. This agent is the German or French soft soap (green soap, schmierseife, savon vert), in alcoholic solution. This soap is now imported in large quantities, and prescribed daily by the dermatologists of Boston, New York, Baltimore, Philadelphia, and other cities. The soap, containing an excess of alkali, saponifies the fatty matter of the sebaceous secretion, and it is thus easily removed. The alcohol greatly assists this action, and seems also to have an alterative action—if such an indefinite term is excusable—on the glands. The two may be combined as follows:—

Saponis viridis (Germ.)........ 2oz.
Alcoholis .................... 2 „
Dissolve, filter, and add from 20 to 30 drops of oil of lavender.

The oil of lavender is added to cover the disagreeable fishy odour of the soap. The above makes a very handsome orange or wine-coloured preparation, with a pleasant odour, to which the most fastidious will hardly object.

This is used as a shampoo every morning or evening, pouring one or two tablespoonfuls on the head. Upon the addition of water, and smart friction with the fingers, a copious lather is soon produced. After keeping up the shampooing process for four or five minutes, all the soap must be washed out of the hair by the free use of warm or cold water, and the hair thoroughly dried by means of gentle friction with a soft towel. The immediate effect experienced is a disagreeable feeling of tension of the scalp, as if it were stretched too tightly over the skull. To obviate this effect, and to keep the scalp from getting too dry, and thus, perhaps, set up a true pityriasis, it is necessary to follow up the shampooing with some fatty application, which may contain some mild stimulant, thus:—Castor oil, one part, to alcohol, three or four parts, with a little oil of rosemary or cinnamon, or the elegant pomades and oils of Bazin and other manufacturers may be used. But the best, as well as the neatest preparation that I have employed for this purpose, is the hydrocarbon known in commerce as cosmoline. This is a product obtained from petroleum. It is entirely bland and unirritating; never turns rancid, and is comparatively cheap. It may be obtained in the fluid form or as a soft solid.

This procedure, shampooing, drying the hair, and applying the greasy preparation must be repeated daily for three or four weeks. In the course of that time it will be discovered that the production of scales and the falling of the hair has been very markedly decreased. It will then suffice to repeat it two or three times a week for a month or two longer, after which a good shampooing once a week will usually succeed in maintaining a permanent cure.

Most patients will be alarmed after using this method at first, because the hair comes out in greater quantity than before. This is due to the fact that a large number of hairs are dead and only retained in their follicles by the plugging of the sheath with the accumulated sebaceous matter. The patient should, therefore, always be prepared for this result, and the cause of the increased falling of the hair explained to him.

It is not necessary, though more convenient, to cut the hair short during the treatment.

When the alopecia has lasted so long that the hair bulbs have become atrophied, nothing will restore the hair on those spots. Our endeavours must be directed to saving what remains. A prognosis favourable to the restoration of the hair must therefore be given with caution.

Atlanta, June 29. **J. T.**

## CASTING IRON ON WROUGHT SHAFTS.

[24531.]—IT is not an easy matter to cast iron on a wrought bar, and the following method, which I found in an American paper, may be useful to your readers. The writer says that the best way he has found is to turn the ends of the iron to be cast in the mould, and cut a thread or screw, and then tin the the part that goes in the mould. "This can be done by mixing muriatic acid and rain-water together. Melt the tin, heat the ends of the iron to be tinned; then put the ends in the pickle for 10 or 15 minutes, and then dip into the melted tin slowly, and let remain in the melted tin about five minutes. Next take out moulds made with wrought-iron shafts cast in. Done in this way, the rolls will be solid and clean and free from vibration. I make about four thousand such castings every year, and for the benefit of my friends I give this information. I cast a roll a few days ago 5in. in diameter, 6ft. long, with a shaft 4in. in diameter running through the entire length of the mould, thus leaving only 1in. of cast iron. In casting this roll, I poured, and made to flow through the mould, about 200lb. of hot melted iron, so as to make the shaft red-hot, and make the cast iron adhere to the wrought. The roll was solid and free from blow-holes. As the roll had to be turned all over the outside, I had to make that amount of iron flow, so that the cast part would not be chilled."

Would some one say if it would be possible to cast brass on iron in a similar manner?

**Foundry Man.**

## 100 TO THE INCH ON TELESCOPES.

[24532.]—As the highest magnifying powers of any telescopes are used chiefly on stars, and especially on double stars, I thought it might interest Mr. Franks and others who are writing on the question of 100 to each inch of aperture, if I extracted from the chief double-star catalogues of the present century such details as to the powers and apertures employed as seemed to bear on this question. I have, therefore, given below the approximate number of *sets* of measures on each night (inclosed in brackets) in each catalogue, counting sets in which only one element has been measured as whole ones; the aperture of the telescope employed; the highest magnifying powers of the micrometers used; and the number of occasions on which such highest powers were used, relative to the whole number of measures. It is quite possible, that in counting so many thousands of figures I may have overlooked a few instances in which high powers have been used, though I have taken some care in counting, and I have not tried as a rule to determine the number of times when the highest power has been employed if that did not exceed 60 to the inch. I have omitted such catalogues as Miller's and Nobile's, in which the total number of measures is very small; catalogues in which the magnifying powers are not clearly stated, as in Cincinnati I.; catalogues made with heliometers; and catalogues now in progress of printing. Of course, in several cases, e.g., that of O.Σ.'s, many more measures than I have given have been made, though they have not as yet been published.

Herschel and South (800). 3¾in. Dollond, usual power 133, occasionally 303; very occasionally, 381; once or twice 571, single lens. A few measures were made, chiefly towards the close of the observations, with the 5in. Tulley, power 179, occasionally 273. Herschel and South's measures were made in the Borough, not far from Guy's Hospital. (No driving clock).

South (1000). The 5in. Tulley was generally used, observing power 181; occasionally a power of 787 was employed. The micrometer of the 3¾in. was used on this instrument after April, 1825. (No driving clock).

Herschel (Sir J.) (6500). A power of 180, single lens, usually employed in the sweeps with the 20ft. reflector, "front view" construction; occasionally 320 was used, and in very rare instances 480, the aperture being then generally contracted to 12in. The total number of measures made with the 5in. Tulley after it was purchased from Sir J. South was (2200); a power of 400 used after March, 1830 (the o.g. previously was pinched in its cell), 500 employed almost always later on, and 400 at the Cape (no driving clock).

Dawes. (627). 3¾in. Dollond. 420 and 460 often used, 625 occasionally (no driving clock).

Struve. (10600). 9·56in. Fraunhofer. A power of 848 used frequently on close pairs after October, 1832. Most of Struve's pairs were discovered with a power of 198. Powers of 1150 and 1500 were supplied in 1832; but Struve says "quanquam in optima aëris conditione imagines fixarum offerunt bene definitas, ad mensuras nunquam usus sum."

Mädler. (10000±). Same telescope. Power never given. I have not taken the trouble to count Mädler's observations, which, indeed, would not be an easy task, but the number made is certainly not below 1000.

Smyth. (1200). 5·9in. Tulley. Powers not usually stated. The highest power of the micrometer was 850. "The telescope bears its highest magnifiers with remarkable distinctness;" the highest power was said to be 1200.

Jacob. (800). 3¾in. Dollond; power 152.

Jacob. (1628). 6·3in. Lerebours and Secretan. Power usually 200. Two object-glasses; the first one bad.

Fletcher. (282). 4·1in. Cooke. Usual power 300, occasionally 420 and 600.

Dembowski. (2100). 5·3in. Plössl (Dialyte). Highest power 300, always used. (No driving clock.)

Dembowski. (18400). 7·5in. Merz. 500 and 670 usually employed on close pairs.

Wrottesley (Lord). (1350). 7¾in. Dollond; usual power 450, 600 and 820 occasionally.

Secchi. (2900). 9·6in. Merz; power not stated, but the observations were usually made when the air would bear 760, and 1000 was frequently employed.

Ferrari. (125). Same instrument.

Powell. (1056). 4·0in. Simms; powers 170 and 280.

Knott. (309). 7⅓in. Alvan Clark; a power of 610 used seven times, 835 once.

Dawes. (2150). The 7·0 Dollond belonging to Mr. Bishop, on which 600 was used very frequently; the 6⅓in. Merz, powers 658, 690, 780, 870; the 7¼in. Alvan Clark, powers 722, 815, 860; and the 8¼in. Alvan Clark, powers 714, 772, 835, 970 (once), were the telescopes chiefly used by Dawes. He also used an 8in. Alvan Clark, powers 697 and 909 (once), an 8in. Cooke, a 7¾in. and a 7⅓in Alvan Clark.

Leyton Obs. (1050). 10in. Cooke ; powers 250 and 430 usually employed.

Dunér. (2700). 9·6in. Merz ; 940 very frequently employed. A power of 1370 was procured at the end of the observations in 1876 ; but though it gives very distinct images, it was never used for double-star work.

Harvard Obs. (1000). 15in. Merz and Mahler ; 1243 and 1560 used sometimes, 2004 on two or three occasions.

Rugby Obs. (3500). 8¼in. Alvan Clark (formerly Dawes's) ; a power of 400 almost invariably employed in the two first series ; in the two last this has been almost doubled by the use of a Barlow lens.

Gledhill. (484). 9⅓in. Cooke ; usual power 400, 750 used on fine nights.

Hall. (1570). 26in. Alvan Clark ; powers 400, 606, 888 ; 1282 used seven times.

Schiaparelli. (1200). 8·6in. Merz and Mahler ; the highest power 690, almost always employed.

Struve (O). (6000). 15in. Merz and Mahler. 858 and 1169 frequently on close pairs, 1458 in extraordinarily favourable states of the atmosphere ; 1822, the highest power, is never used.

Doberck. (700). 13·2in. Cauchoix ; usual powers 300 to 600 ; object-glass not very good, frequently stopped down. Driving clock bad.

Jedrzejewicz. (1560). 6·4in. Steinheil (no clock). 480 frequently used in the first series ; 760 and 800 often employed in the second.

Cincinnati. (371). 11·0in. Merz and Mahler (no driving clock). Usual power 230, 500 on a few occasions.

Cincinnati. (3930). Same telescope. Object-glass refigured by A. Clark and driving clock employed. A power of 1320 used fourteen times, 1500 eleven times. Usual power 450.

Burnham. (460). 460 new double stars *discovered* by him with 6in. A. Clark, powers 212 and sometimes 400 (no driving clock).

Burnham, Chicago. (3900). 18½in. A. Clark. Most of the close pairs were measured by Mr. Burnham with the highest power, 925.

Burnham, Washburn. (1050). 15½in. A. Clark. Close pairs measured usually with highest power, 750.

Perrotin. (330). 13·9in. Henry Bros. 750 and 1000 almost always used.

Sydney Obs. (1400). A 7¼in. (?) Merz, usual power 159, occasionally 580. Later on 11·4in. Schroeder, powers (?) – 800 sometimes used on close pairs. I am unable to understand the observations.

July 21st. **H. Sadler.**

## WHY DOES NATURE GROW TREES IN GROUPS?

[24533.]—The question has often been asked why immense areas are sometimes found covered with trees of one species, and here and there in the midst of a varied vegetation we occasionally find considerable patches of ground occupied exclusively by trees or plants of one species. One cause of this phenomenon may possibly be found in the facts related by Mr. J. S. Campbell, in the *American Naturalist*. Some have ascribed the phenomenon to a peculiar fitness of the soil to particular kinds of vegetation, which he does not find to exist. His own explanation is very simple, and is to the effect that the matter lies wholly or mainly in the fact of the ground being in a fit condition to receive the seeds of the various species when they fall upon it. Seeds of different kinds fall at various seasons, and when the ground is in various conditions as to moisture, &c. Those that find the ground in good condition sprout and grow, if no accident occurs to remove the plants when very young. Mr. Campbell has tested this view in his surveys in the occasionally flooded bottom-lands of the Wabash River, and illustrates it by following the futures of the seeds of three species of trees. The balls of the sycamore or button wood begin falling early in the spring months, and if a flood is receding at the time, they stick to the soft, moist banks wherever they touch them, and particularly along the highest parts of the sand bars. Were it not for the subsequent floods in the same spring, no other trees could grow, for these would occupy the ground. But they are easily killed during their infancy by overflows, and this is what happens to most of them. The cottonwood is the next in order of shedding seed, and if another flood is receding while this is taking place it will have killed all the sycamores which it has covered, and sprout the cottonwoods. These in turn may be killed by the next floods. It is the turn of the maples next to shed their seed and try for the ground. If either of these species succeeds in making wood without a flood, it will hold the ground, and its rivals will not be able to get a place. Last spring the edges of the successive plantations escaped the next floods after the seeds fell upon them, and Mr. Campbell could see along the river banks three belts of young trees, and distinguish them by their general appearance. The upper belt was of sycamore, the second (downward) of cottonwood, and the third of soft maple. In June a bigger flood came than any that caused the seeds to sprout, and killed all the young trees. Probably there are other reasons. If so, I should be pleased to read them. **E. G. M.**

## MELTING STEEL IN AN ORDINARY CUPOLA.

[24534.]—I noticed recently in your excellent paper some remarks about cupola blast and steel melting. I send you some notes I have made on the method adopted by Mr. R. E. Masters, one of our foreman moulders in the railway shops.

As soon as the last charge of cast iron begins to settle away from the charging door, in melting 2,000 pounds of steel in two charges in the 30in. cupola, we put on 200 pounds of coke and 1,200 pounds of steel, then 100 pounds of coke and 800 pounds of steel, melting at the rate of 6⅔ to 1. We keep the cupola full of steel up to the charging doors until the last has been put on; this gives it the benefit of a longer heat, and when it reaches the melting point it comes down—to use the expression of a moulder here—"hot enough to run a needle with the point up." It is very fluid when it first comes from the cupola. While it does not remain fluid as long as cast iron, I am satisfied a very large piece could be poured with it. I notice by agitating it in the ladle it "gums up" around the ladle quicker than cast iron.

Charging in this manner, the cast iron all melts down ahead of the steel. Then there is a cessation in the melting for a few minutes before the steel starts; once started, it melts very fast. The appearance of the metal is so different from cast iron in the fluid state, that we can tell it as soon as it starts from the cupola. This steel scrap is of a class known as "slab or agricultural steel," and we have melted 60,000lb. out of 75,000lb. I stated we had on hand, besides using up all the scrap that has been made since then. We are going to try a part of the heat of steel rails as soon as we work up what scrap we have on hand. By itself the steel runs porous. By adding one-sixth cast iron to the charges we find it runs the castings very close and solid, and harder than the steel alone. For furnace liners, back plates, grate bars, brake shoes, &c., it is superior and more serviceable than cast iron. In light castings annealed I feel sure it would make stronger castings than malleable iron.

Last Fall J. C. Albrecht, M.M. of the railway shops here, complained about the chilled truck wheels shipped him here for section masters' hand-cars, cutting out and getting flat places in them in a short time. We asked him to let us make a set of steel rim wheels for a trial. He placed an order with us for two sets of wheels, steel rim, 26in. dia., 3½in. face, ¾in. thick, 1in. flange, ten ¾in. round wrought-iron spokes, set zigzag in hub, hub of cast iron, weight of wheel 120lb. They have had to stand the test through the most severe winter we have had in the South for years. Having filled orders for 150 since then is evidence of the satisfaction they are giving.

Chicago, July 11. **J. C. B.**

## LIFE WITHOUT OXYGEN.

[24535.]—In the *Revue d'Astronomie* for July, 1885, M. C. Flammarion writes:—"The bacillus Amylobacter, which is found in butter, not only does not require oxygen for the support of its life, but this gas actually kills it when brought in simple contact with it. The Amylobacter is the ferment of butter, and attacks substances the most diverse, always producing butyric acid. It develops itself in situations most adverse to other forms of life, and is found most profusely in nature."

**W. B. Kennan.**

## KING'S CROSS ACCIDENT.

[24536.]—"Nun. Dor." (letter 24490, p. 432) is right: there was the usual "blunder" and the everlasting "goods" train; but I think we had better not say whose fault it was before the inquiry.

**Midland.**

**Tobacco and Cholera.**—The Anti-Tobacco Society of France has offered a prize for the best essay bearing upon the question of the liability or otherwise of smokers to contract cholera. As the object of the Society in offering the prize is stated not to be the condemnation of tobacco in the face of facts, but to ascertain the facts as they are, the essays must not be based upon theories, but must be supported by actual occurrences, although the anti-tobacconists would very probably not be displeased to find themselves supported in their hobby by statistics. If a healthy stomach be a safeguard against cholera, it is possible that excessive smoking may dispose to the disease by disordering digestion.—*Lancet.*

# REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[56620.]—**Steam-Carriages.**—On p. 437, near end of letter, "Progress (4)" a small compositor's error crept in, which rather destroys the meaning. For 87½ per cwt.," read 87½ per cent. "Nun. Dor." seems lost in "wonder" on the subject; but he must "move on" with the times, or stand on one side. The piston's pressure on the road, as spoken of, is not a long, but a short stroke, a few ounces of h.-p. quickly repeated, a mere throbbing motion, such as you might conceive to be at work in an elephant when locomoting. We want now a family carriage for the newly-enfranchised—useful and cheap—such as will be required by the thousand when the system of iron bearing on roads is generally adopted. The new Coventry tricycle chair is approaching the style, but requires to be enlarged as a four or six-wheel carriage, and fitted for all its occupants to assist in applying motive-power, either by hand or foot. "Thrift" is my motto, in all its parts and workings. The weight of vehicles now generally used is double what will in future be required, and the present waste of motive-power, both mechanical and animal, is, in many cases, as much as that advantageously used. For the storage and transmission of power is a wide field open to mechanical genius, and any person who can in a simple way store the power supplied by a fixed steam-engine, and transmit it for locomotive purposes, would secure an easy fortune. Electricity at present does not satisfactorily perform the operation. I spoke of a competition having commenced between tram-cars and a new style of omnibus with wheels fitted to gauge to run on the rails. The omnibus when on the rail is admitted as decidedly of easier motion than the car. The car's fares are reduced one-half, and the result is the cars keep fully loaded, and the omnibuses also have a satisfactory share of patronage. During the week ending July 4th the tramway company carried no fewer than 140,425 passengers, by which, at one penny each, they would net the respectable sum of £585 2s. 1d. for their week's work. When the iron bearing is generally provided by the road authorities, the charges will probably settle down to one halfpenny per half mile, and people will at most all times ride instead of walk, either short or long journeys, as they please, and thus pay for the distance they ride, and that distance only.—Progress (5).

[56650.]—**Lead Burning.**—To W. Man.—Seeing your letter headed "Lead Burning," readers would naturally suppose that you have tested the apparatus there mentioned for lead burning, although your letter does not in the least state that you have done so. If you have, I shall feel obliged if you will refer me to any place where you have done lead burning with this apparatus, as I should like to compare it with the work done with the ordinary lead-burning machine. I may mention that I shall test the machine myself, but should prefer to see the work of others, especially that of another professional lead burner. Please reply.—P. J. Davies.

[56650.]—**Lead Burning.**—I cannot speak in favour of Briggs's machine for lead burning, especially as I cannot get one to test; but will write its merits after I have tested the same. The specimens of lead burning in the exhibition are not what they should be, and if they are fair samples of what the machine can do I should say that the old system of generating gas, &c., is decidedly the best plan. I have written to Messrs. Briggs to send the machine for testing, but they have not sent one, although I told them that I would not detain them more than an hour in making the test.—P. J. Davies, 78, Earl's-court-road, Kensington.

[56676.]—**Free Reeds.**—I cannot follow Mr. Fryer in his remarks on p. 437, because I know nothing about his private correspondence. I referred merely to a query which appeared in these pages and to a so-called reply. The querist on p. 268 (56676) asks clearly enough how he can make a "tuning apparatus for harmonium reeds," and towards the end of his query he implies that he wants to use it for tuning other reeds as well. Now, Mr. Fryer notwithstanding, this apparatus is perfectly well known as a "tuning bellows," and certainly every reed-tuner who has to do with American organs has one: hence the reply on p. 288 was, and is, simply nonsense, whatever private correspondence may have passed. I think Mr. Fryer is mistaken in asserting the identity of two querists, for the second querist gives unmistakable evidence that he knows a little more about harmoniums than a gentleman who, on p. 220, appears to be undecided as to the price of reeds, though he "retains an unalterable opinion that 18s. is a very moderate charge for a set of reeds of good quality" —why not best? Mr. Fryer's way out of the blunder is to answer the query without reference to his private correspondence.—G. L. B.

[56796.]—**Boiler.**—"W. W." will find the error of 2oz. instead of 2lb. was duly corrected and explained on page 416.—INVICTA.

[56797.]—**Lamp Wick.**—Some carefully selected samples of Italian asbestos will answer well for lamp wicks; but I have generally found that it has not the lifting power of the cotton wick. That is remedied by keeping the oil nearer the seat of combustion.—ESSAR.

[56799.]—**Sand for Cores.**—"G. G." had better procure the "sand" from those who deal in foundry materials. The sand he finds in plenty "in the country" is not exactly the material to use, without examination by an expert. Moulding sand should be nearly all pure silica, with about 3 per cent. of alumina, and, say, 1 per cent. of oxide of iron. Sand containing lime, magnesia, and oxides of metals will not do. If "G. G." has plenty of sand, he should wash it thoroughly, and temper it with clay water when moulding up his cores.—E. G. M.

[56801.]—**Organ.**—Might not this querist just as well ask how much water it takes to blow an organ with a polished pine case, as with three rows of keys? It depends on the number of pipes and the pressure on which they are voiced, and to be safe he must allow wind enough for all the stops at once. I would recommend "A. H. F." to inspect Willis's organ at the "Inventions," and then, perhaps, he will conclude that it is much cheaper to use a gas-engine. Willis's organ is blown by hydraulic engine, but it is fitted for working by a belt from a motor, while the high-pressure chests are supplied by hand.—N. E. CHILD.

[56805.]—**Torrigelli Barometer.**—Perhaps this querist will explain where the Torrigelli dial can be seen. Surely he cannot mean the Torricellian barometer. That is without a dial.—NUN. DOR.

[56808.]—**Alcohol.**—An alcoholometer or hydrometer will read the proportions of water and spirit accurately enough for a "rough test."—INCISE OFFICER.

[56810.]—**Stamp Duty.**—"J. C." seems to imagine that the stamp on a cheque is the equivalent of a receipt stamp. The payer of a cheque pays for the stamp on that, and the giver of the receipt pays the penny for the receipt stamp. The stamp on the cheque has nothing whatever to do with the receipt of the money; but is a means of raising revenue in a very satisfactory manner.—INCISE OFFICER.

[56838.]—**Telescope.**—Thanks for the advice given; and, although I cannot do the job myself, I should be glad of more. I have an ordinary eyepiece by me. It has been tried with the erector in a paper tube, shortened by degrees until objects were seen, but not clearly; hence the idea of cutting the brass-drawer accordingly. I am afraid a Barlow lens would cost too much.—EYEPIECE.

[56948.]—**Gas-producing Apparatus.**—Many thanks to "Invicta" for his reply to my query. I have referred to the back numbers as directed, and think that the apparatus you there describe would answer my purpose very well, but would be obliged for a little more information from you as to (1) the dimensions of the apparatus (my engine-cylinder is 4in. diameter, 7in. stroke, 180 to 200 revolutions per minute). (2) Would the generator and pump do to be square instead of round, as I think the patterns would be more easily made? (3) Are benzoline and gasoline different names for the same thing; if not, which gives the best gas? (4) What would be the probable cost of this gas per 1,000 cubic feet, and what is its strength as compared with coal-gas, for driving a gas-engine? If you could get me a set of castings for one of these generators, I will advertise my address: it would save me the trouble of making patterns, &c.—GASEOUS.

[56949.]—**Aluminium.**—In a reply under this head, I read with astonishment that "F.W.G." has obtained Ca from CaO, and found it to be a "beautiful white metal," which "will not oxidise." Has "F.W.G." a specimen to spare?—S. R.

[56949.]—**Aluminium.**—I would strongly advise "F. W. G." (page 438) to patent his process for obtaining aluminium without delay, and get it into operation as soon as possible. He is incorrect in stating that calcium does not oxidise, as it rapidly tarnishes in moist air, and decomposes water in the cold readily. Aluminium costs about 100 francs per kilogramme. What has become of "A. E. S." and his process? We have been promised cheap aluminium so often, and it has never come.—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56956.]—**Ball Bearings.**—F. J. Ganard says I am mistaken about gun-metal bearings, and says the grit on an ordinary road would cut gun-metal bearings to pieces in a week. He is evidently not at home on the subject: he says, in ball bearings the grit gets between the balls but not on the bearing surfaces. Now, the fact is this: the ball bearing box becomes full of so much macadam, and when you work your machine you are using your best to grind up this material. Now if you look at the action of the balls when the wheel is running, you will find that the balls don't run in harmony with each other, but run in a contrary way that is rubbing against each other, and not rolling together as they should do. Furthermore, I know several first rate riders who are thoroughly opposed to ball bearings.—CHAS. HOSKEN.

[56956.]—**Ball Bearings.**—"Secundus Haud Ulli," on p. 438, thinks I am wide of the mark in comparing the bearings of a bicycle or tricycle with those of a steam-engine, and says, in the one case you have steam as a great force, and in the other the slight power exerted by a man's body, therefore requiring only very small bearing surface. He seems to forget that whether you have steam or manual labour as a motive power, that all machines should be arranged to produce as little friction as possible, because with unnecessary friction in machinery driven by steam the consumption of fuel will be greater than it need be; so also with a tricycle: if your friction is greater than necessary, you will have to expend more labour to drive your machine. Because you have driven your tricycle 5,000 miles this is no proof that ball bearings are better than I have advised. Try both arrangements, and then I shall be glad to have your opinion. I can quite understand when you renewed your ball bearings you obtained the same result as before the bearings wore out; this is only reasonable, but no proof in favour of the ball bearings. Again, he says if proof is wanted, take out the balls and run the machine on the collars. Now this is no proof, because the collars are not broad enough to hold the lubrication. I still advise all bicycle or tricycle riders to have nothing to do with ball bearings unless you are prepared to exert more labour than is necessary. I look upon the ball bearings only as a new-fangled idea.—CHAS. HOSKEN.

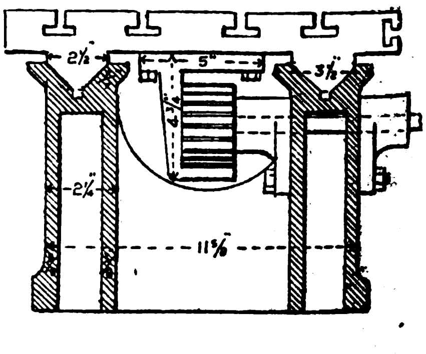
[56961.]—**Boating.**—Mr. Hundel's explanation is not as clear to me as might be desired. But a little consideration at once made the whole theory clear to me. Whilst the motion in question would produce in a boat motion and by means of the differential motion as well, it is competent to make one wheel go ahead whilst the other goes astern, or vice versâ, which is no doubt the novel point in the arrangement, yet I must confess I don't like the idea of having a handle athwart ships to get motion. It is so very like an organ-grinding motion. By the apparent sizes of the wheels the paddles must be either very small or they must go far too slow to get much speed out of the boat. Like all other matters, mechanical speed means power; and power is lost at each right angle of the arrangement. I have seen in London more than one trial of paddles driven by man power; and the most successful of all was a boat in which the wheels were driven by winch handles on the wheel shafts themselves. These being just long enough to grasp with one hand, allowed a free passage to pass fore and aft. The power was applied directly to the wheels; whilst almost a tyro could go ahead one wheel and back the other. An arrangement was subsequently proposed by myself so that two human motors could be applied, or even four; the handles being made to give a long or short throw, and to—by means of a sliding motion—couple both wheels. The way a powerful aquatic friend of mine propelled me along on one occasion was simply immense. The action being so much like rowing, he seemed to propel the boat quite easily after starting, with very little exertion. If the particulars or sketch would be of interest generally, I would look up the drawings made at the time.—INVICTA.

[56967.]—**Deafness.**—In my reply to this query which appears on p. 439, I find that I have unintentionally used a wrong term, as the word "tumour" has been written instead of the term "abscess," but the reply, being written in a hurry, will perhaps be a sufficient excuse for the mistake made. I may here inform the querist that any obstruction in the transmission of sounds of any kind through the external cavity of the ear will cause deafness. All sounds are conducted to the ear through the air which enters through the eustachian tubes and the external cavity of the ear. When the eustachian tubes are blocked by inflammation, through the effects of a cold, the internal cavity of the ear is deprived of the air which is necessary to produce the action of the various parts of the mechanism of that portion of the ear. The intensity of the deafness from this cause will depend on the amount of air which is prevented from entering through the eustachian tubes. Accumulation of wax causes deafness, because it obstructs the necessary amount of air which passes through the external portion of the ear to the drum. If air enters freely through the eustachian tubes, and there is also nothing to obstruct the entrance of air through the external portion of the ear to the drum, then the cause of deafness would probably result from the perforation of the drums, or some other organic disease of the ear, the existence of which could alone be ascertained by personal examination, and that only by a competent medical man, skilled in the treatment of diseases of the ear.—G. FRYER.

[56969.]—**Hydraulic Ram.**—"Invicta" is quite wrong in supposing that "the valve is made in itself heavy enough to more than balance the permanent head of water." Such a valve could not work. Let him just consider what weight this would imply for, say, a 3in. valve with an ordinary fall of 10ft.; or let him add weights to any ram he can find, until "the permanent head of water is more than balanced." The valve will fall, but he will wait in vain for it to rise again. There is, of course, a recoil, as "Invicta" goes on to say, removing the pressure from below the valve. In this lies the whole gist of the thing. But why does the water recoil? I searched in vain for a reply to this question until I came across a French work, Gen. Morin's, "On Machines for Raising Water," which gives in substance the explanation which appeared in my reply last week. I should like to answer "R." (57071), but I am afraid too much space would be required. Let him consult Morin. No English work on the subject that I know of, and I have seen most of them, will give him any help. The reason why rams have not been in favour with engineers I take to be this: that, until lately, as made by some makers of repute, they have been liable to frequent vexatious stoppages. This is simply a result of the neglect with which the theory of the machine has been treated. There is no difficulty in constructing rams, and they are now constructed by some makers to work on continuously from month to month without so much as being looked at or requiring one drop of oil, and all the time returning 60 per cent. or more of the power. Is there any other machine of which this could be said?—W. A. S.

[56978.]—**Engine Query.**—To "BACCHUS."—Would you please say how you get the throw of valve 4½in. and eccentric 120° in advance of crank? Please make it as clear as possible and oblige—A. B.

[56985.]—**Planing Machine.**—The annexed sketch will furnish the dimensions you require. In answer to your first question: the carriage would lift under heavy cuts, hence the reason why I put Vee strips to it in Fig. 8, page 468, of Vol. XL. For the second, I have drawn the loose flanged sleeve as you suggest, and if you look at Fig. 62, page 161 of the present volume, you will see a simple boss cast on the bed as an alternative to the plummer blocks, and this is the more common way of carrying the spindle in small machines. Of course, having the flanged sleeve loose for bolting permits of more exact adjustment of the spindle centres in case of inaccurate marking out and fitting. Employing that also, I should dispense with the inside bracket, and simply put a second sleeve bearing within the frame cast from the same pattern as the one on the outside, as shown in the figure.



I see no advantage, but extra trouble, entailed by adopting the double Vee grooves in preference to the flat and Vee method. The mutual fitting must needs be very accurate, and I do not know of any very small machines fitted up in this way, though there are plenty of moderate size, say of 3ft. or 4ft. travel and upwards. However, I have shown how the pattern requires modification. If the sides were formed of a single rib only, as in Fig. 55, page 161, the overhang of the Vee'd edges would be a source of weakness, since an accidental blow might easily knock out a piece. Hence, the sides should be boxed up to support the edges which lean over. The machine looks all the stiffer for the alteration, but is not any more efficient. If you do not mind the extra trouble, you will find the thicknesses given neither too thin to cast well, nor wanting in rigidity. In reference to the suggestion you make respecting the advertising of the cost of a set of castings partially machined, I can render you no assistance, but make no doubt the Britannia Company would be willing to answer any queries addressed to them on that matter.—J. H.

[56986.]—**Pansies.**—The expression "plants eaten off" leads to the question: Are you sure wireworms did the mischief? For wireworms work underground, and eat the roots. Petroleum-and-water is no protection, for if you asked them, wireworms would doubtless say they rather liked it than not. The best traps are, certainly, carrots and potatoes placed in the ground, the latter with little signal sticks stuck in them to mark their positions. These are to be taken up every two or three days and examined, when the wireworms will be found sticking in them. I suspect, however, that you mean woodlice, the little fellows that curl up into a ball when touched. Wireworms are very tough, and resemble bits of brass wire.—Nun. Dor.

[56988.]—**Siphons.**—If the outside and downward limb of the filled siphon is made short, so that its open end is above the level of water surface in tank, the water will flow back again into the tank, because the pressure of the water at the open end of the pipe is less than that of the atmosphere at the same point. If the end of the limb is held level with the surface, the water is in equilibrium and consequently at rest. When, however, the limb is lengthened so that the pipe really becomes a siphon, the atmospheric pressure is less than that of the water, because the water has *head* plus atmospheric pressure; consequently flow is created in the downward limb, inducing vacuum, which is satisfied by corresponding flow in upward limb, through outside atmospheric pressure. The greater the length of the downward limb, or, rather, the greater its *fall*, the greater the velocity. This is, however, limited by the capacity of the pipe in respect of friction, and the amount of atmospheric pressure due to the height of the siphon above sea level, and also the "weather."—Surveyor.

[56989.]—**Willesden Canvas.**—"R." will find a fairly full account of the process in No. 1,002, in an article entitled "Cuprammonium as a Waterproofing Agent."—S. R.

[56994.]—**Lobster-back Cowl.**—I have seen chimney cowls made with alternate laps. Large steel cowls I have seen beaten out of the plate; but these would scarcely be called "lobster-back." Please give number and page of query about copper band, and I will reply if I am able. It is always as well to refer to the page when speaking of a former communication.—Glatton.

[57001.]—**Carbon.**—I am afraid that the carbon and zinc plates immersed in "chloride of sodium" would be no use to ring bells, drive motors, &c.; if, however, they are immersed in a solution of bichromate of potash in dilute acid, he will be able to use them for those purposes. If he wants a battery for bell-ringing he should have a Leclanché.—Accumulator.

[57003.]—**"J. K. P.'s" Gas-Engine.**—I believe the quantity of gas consumed in the engine that I fitted was 18ft. per hour when doing all it could. About 9ft. of gas when running free; rest of question cannot say. Sorry for delay in answering; had not measured the gas myself.—J. K. P.

[57014.]—**Watch Jobbing.**—The best tool for your purpose will be a pair of ordinary Swiss turns (steel), with a good assortment of brass and steel runners. These turns can be adjusted to any size, according to the size of the work which you want them for.—C. A. W.

[57015.]—**Steam Canoe.**—If this querist will take a word of advice, which has certainly not been asked for, he will not attempt to drive an 8ft. canoe by means of a steam engine; for he is sure to be disappointed.—R. T. Y. C.

[57020.]—**Piano Repairs.**—To Mr. Davies.—So much depends upon the size of the holes in the wrest-plank, and their relation to each other. If they have not been bored more than $\frac{1}{16}$in. too big, and are ranged in alternate rows, it will answer very well to plug them with a beech dowel, and, in boring for the fresh holes, to leave the crescent-shaped piece of wood at the top of the hole. If the holes have been bored in only two rows, it will, perhaps, be better to strengthen the plank with an iron face plate, about No. 17 B.W.G. For this purpose it will be necessary to take a pattern of the holes as they now are by fitting a piece of brown paper above the bridges, and rubbing over the holes with black heelball. The cost of this would not much exceed 7s., and will greatly increase the strength of the plank. If, after all, it should be found necessary to chip away the plank, it is no use attempting to do it simply above the bridges; but the whole of the plank must be taken away, and the bridges removed with a hot iron first. Such pieces of wood as may be found here and there adhering to the pine plank should also be burned off, or the pine would be liable to tear.—W. H. Davies.

[57024.]—**Dead Centre.**—The setting of the slides may be all right; but sticking on centre may result from one of many causes. It may be from the lap of the valve causing excessive cushioning, thus pulling up the engine; or it may, and very likely is, due to an insufficient balance weight, the same being not accurately counter-weighted to balance the weight of crank, connecting-rod, cross-head, &c., so that the piston tends to go to the bottom centre and stop there. Is the stern tube stuffing box too tight? I prefer these to be as easy as practicable, as a slight leakage inboard is an advantage. If you cannot see your way out from what I have stated, the only other suggestion I can make is that you should take accurate templates in, say, stout drawing paper, of the slide valve and cylinder ports, at same time stating bore of cylinder, stroke, and pressure of steam, and revolutions per minute. If you can tell me the approximate weight of parts, I would also tell you if the counter-weight was sufficient. I suppose your engine is a single cylinder high-pressure? I wonder how long amateurs will still ignore the benefit of making even single engines on the compound principle.—Invicta.

[57025.]—**Midland Scotch Express.**—The number of the ill-fated driver's engine was No. 819, one of the far-famed 800 class.—Piston Rod.

[57025.]—**M R. Express.**—The engine was 819 that that poor driver was killed upon. He had to go to top of tender to see how much water there was in the tank. Why can't all tenders have a gauge glass and taps to save this dangerous practice?—Midland.

[57026.]—**Problem.**—Let $x$ $y$ $z$ be the number of gallons of 16s. whisky, 19s. whisky, and water. Then—

$$x + y + z = 51 \quad \ldots\ldots\ldots\ldots\ldots (i.)$$
$$16x + 19y = 12 + 51 = 162 \ldots\ldots (ii.)$$

But $16 \times 6 - 19 \times 5 = 1$ ∴ from (ii.) we get

$$16 (x - 6 + 612) + 19 (y + 5 + 612) = 0.$$

$16 (x - 6 + 612) + 19 (y + 5 + 612) = 0$. ∴ $x = 6 \times 612 - 19\,t$. $y = 16t - 5 \times 612$. where $t$ is any integer. The values of $t$ giving +ve integral solutions are $t = 192$ or $193$. If $t = 192$, $x = 3{,}672 - 3{,}648 = 24$gals., $y = 3{,}072 - 3{,}060 = 12$gals., and ∴ $z = 51 - 24 - 12 = 15$gals. If $t = 193$, $x = 3{,}672 - 3{,}667 = 5$gals., $y = 3{,}081 - 3060 = 28$gals. ∴ $z = 51 - 5 - 28 = 18$gals.—T. H. L.

[57026.]—**Problem.**—Let $x$, $y$, $z$ represent the several quantities of 16s. whisky, 19s. whisky, and water; then—

$$x + y + z = 51,$$
$$16x + 197 = 12 \times 51 = 712;$$

whence, by eliminating $x$, we get $3y = 16z - 204$; an indeterminate equation, which may be solved thus—

$$y = 5z + \frac{z}{3} - 68, \text{ a whole number.}$$

$$\therefore \frac{z}{3} \text{ is a whole number; let } \frac{z}{3} = s;$$

hence—

$$z = 3s.;\ y = 16s. - 68;\ x = 119 - 19s;$$

and $s$ must be such that $16s. > 68$ and $19s. < 119$. The only whole numbers fulfilling these conditions are 5 and 6; so the answer is $x = 24$ or $15$; $y = 12$ or $18$; and $z = 15$ or $18$.—J. P. Bidlake.

[57026.]—**Problem.**—The following is a solution of "Bogie's" problem. (N.B. Water is supposed valueless. Is this one of Bogie's "unknowns?")

51 gallons at 12s. per gallon = 612s.
Let $x$ = number of gallons at 16s.
and $y$ = " " 19s.

$$\text{Then} \quad 16x + 19y = 612 \quad \ldots\ldots\ldots\ldots (i.)$$
$$\text{Divide by 16, } x + y = 38 + \frac{4 - 3y}{16} \quad \ldots\ldots (ii.)$$

Equation (i.) is integral, therefore equation (ii.) must be. Assume

$$\frac{4 - 3y}{16} = t, \text{ or } 4 - 3y = 16t \quad \ldots\ldots\ldots (iii.)$$
$$\text{Divide by 3, } \frac{4}{3} - y = 5t + \frac{t}{3}$$

As before

$$\frac{4 - t}{3} \text{ must be an integer} = s \text{ (say).}$$
$$\therefore t = 4 - 3s.$$
$$\therefore \text{From (iii.) } 4 - 3y = 16 (4 - 3s)$$
$$\text{or} \quad y = 16s - 20 \quad \ldots\ldots\ldots\ldots (iv),$$
$$\text{and from (i.)} \quad 16x = 612 - 19y$$
$$= 612 - 19 (16s - 20)$$
$$\text{or} \quad x = 62 - 19s \quad \ldots\ldots\ldots (v).$$

If in (iv.) $s = 2$, we have $y = 12$, $x = 24$, and, ∴ 15 gallons of water are required. If in (iv.) $s = 3$, we have $y = 28$, $x = 5$, and ∴ 18 gallons of water are required. (Any other integral values of $s$ are impossible). I fail to understand what "Bogie" means by "elimination between three unknowns." There are only two unknowns, and but one relation between them; hence no elimination can take place.—L. N. W.

[57026.]—**Problem.**—Any quantity of either whisky you please, with enough of the other to make up the value of 51 gallons at 12s.; then add water enough, at nothing a gallon, to make 51 gallons. There are not three unknown quantities, and the number of solutions is indefinite. 17 gallons of each would be a correct answer.—J. K. P.

[57026.]—**Problem.**—The problem is indeterminate; that is, admits of any number of solutions, for there are three unknowns, but not three independent equations connecting them. Evidently we may assume $x$, the cheaper lot of whisky in the mixture, to be anything we please, then equation $16x + 19y = 612$, gives us $y$ the other lot of whisky; the remainder of the 51 gallons is water.—W. A. S.

[57026.]—**Problem.**—No wonder that "Bogie" cannot eliminate his unknown quantities in this problem, for, as he has put it, it admits of an infinite number of solutions. 51 gallons at 12s. per gallon come to 612s. Now, 612s. may be made up in a good many ways by multiples of 16 and 19, and as the water costs nothing, there will be clearly an infinite number of answers. If he likes to see it algebraically expressed, here it is: taking $x$ as the number of gallons of 16s. whisky, and $y$ of 19s. $16x + 19y = 612$; and by giving any value he pleases to $y$ he can solve for $x$.—Garrison Gunner.

[57026.]—**Problem.**—This may be solved algebraically with *two* unknowns, and as an indeterminate equation, thus—

Let $x$ = No. of gallons of whisky at 16s.,
$y$ = " " 19s,
$51 - x - y$ = " water.

$$\text{(I.)}\ 16x + 19y = 51 \times 12s. = 612,$$
$$\text{dividing by 16, } x + y + \frac{3y}{16} = 32 + \frac{4}{16}.$$
$$\therefore \frac{3y - 4}{16} \text{ is integral.}$$
$$\text{Multiplying by 11, } \frac{33y - 44}{16} \text{ is integral}$$
$$= 2y - 2 + \frac{y - 12}{16}.$$
$$\therefore \frac{y - 12}{16} \text{ is integral.}$$
$$\text{Let } \frac{y - 12}{16} = t.$$
$$\therefore y = 16t - 12.$$

1st. Let $t = 0$, then $y = 12$ = gallons at 19s., and from (I.) $16x = 612 - 19y = 384$.

∴ $x = 24$ = gallons at 16s.,
$51 - x - y = 15$ = " of water.

2nd. Let $t = 1$, then $y = 28$, $x = 5$, $51 - x - y = 18$.
∴ there are two solutions, viz.—

(1) 24gals. at 16s., 12gals. at 19s., 15gals. of water.
(2) 5 " , 28 " 18 "

—J. Bartlett, Woking.

[57026.]—**Problem.**—No wonder "Bogie" cannot eliminate the three unknown quantities in his problem, seeing that he has but two equations to work with. Let $x$ and $y$ denote the number of gallons at 16s. and 19s. respectively. Then—

$$16x + 19y = 612 \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (i.)$$

There are an infinite number of solutions to this equation, any one of which will satisfy the conditions of the question. We may assume any value for one unknown, and by substitution find the corresponding value for the other. Thus, if $x = 4$, we find $y = 28\frac{16}{19}$, and we shall require $18\frac{3}{19}$ gallons of water to make up the full measure of 51 gallons. Though there are an infinite number of solutions to equation (i.), there are only a finite number of positive integral solutions. Possibly these are what "Bogie" wants. Divide (i.) by 16,

$$\therefore x + y = 38 - \frac{3y - 4}{16}$$

The fraction $\frac{3y - 4}{16}$ must be integral. Let it $= p$, so that $3y - 4 = 16p$, from which we have—

$$y - 5p - 1 = \frac{p + 1}{3} = q \text{ (say).}$$

From these equations we can at once write down $x$ and $y$ in terms of a single integer $q$—

$$x = 43 - 19q$$
$$y = 16q - 4$$

We see at once that the only admissible values of $q$ are 1 and 2, from which we obtain these two solutions—

| | At 16s. | At 19s. | Water. |
|---|---|---|---|
| | 24 gallons. | 12 gallons. | 15 gallons. |
| or, | 5 " | 28 " | 18 " |

—C. Planck.

[57027.]—**Pure Phosphorus.**—Phosphorus has a tonic and stimulant action on the nervous system, repairing the waste of tissue: but the highest authorities on therapeutics (Ringer and Farquharson), and the greater part of the members of the medical profession, are strongly of opinion that no more overrated remedy has ever been introduced into practice, that its action as a general tonic is most uncertain, if it exists at all. There is a good preparation, "Fellow's Syrup of Hypophosphites," which has been found efficacious in severe cases of mental depression and nervous exhaustion; but I should strongly advise "Phos" not to take this or any other form of phosphorus, unless he takes it in the form it exists in eggs, oatmeal, &c., except under the advice of a medical man. If, however, "Phos" feels inclined to experiment on himself with "pure unoxidised phosphorus" for his own sake, or for that of his fellow-sufferers, he should dissolve pure, well-washed amorphous phosphorus in almond oil or ether, and have this made up by a chemist into pills each containing 1-30th gr., and to take one twice or three times a day.—Medicus.

[57027.]—**Pure Phosphorus.**—Let me advise "Phos." to be very careful about taking phosphorus. It is a very dangerous drug, and should be taken with great caution. I suppose "Phos." knows that the dose is only $\frac{1}{40}$gr. to $\frac{1}{20}$gr. For nervous exhaustion "Phos." had much better try the effect of safer tonics, as quinine and iron, with suitable food, outdoor exercise, and, if possible, change of air.—Medicus.

[57027.]—**Pure Phosphorus.**—Will Mr. Alfred H. Allen forgive me if I reply to this? Pure phosphorus may be readily obtained from ordinary commercial phosphorus, by redistillation in an atmosphere of carbon dioxide. But let me earnestly caution "Phos" against making experiments upon himself with phosphorus. It is a most violent poison, 1-30th of a grain being a good dose even for allopaths; while our friends the homœopaths give it in doses which rarely exceed 1-1000th of a grain. The effects of phosphorus in nervous disease are, to say the least, problematic; it has been supposed, because phosphorus is found in the brain (in the form of an organic acid), that, therefore, brain food should contain phosphorus, and this had led some medical men to prescribe phosphorus. But phosphorus *per se* is insoluble in water, and must be dissolved in oils, in ether, &c., and then, owing to its irritant action when pure, can only be employed in the most infinitesimal quantities, quite insufficient to keep up the supply required. Our natural source of phosphorus lies in bread, the cereals, fish, and such soups as are made by boiling down bones in a digester. All these bodies contain phosphorus in a highly assimilable form—viz., as calcium phosphate, which in the presence of gelatinous matters by which it is accompanied in these foods, is quite soluble in the fluids of the stomach.—S. Bottone.

[57028.]—**Stamping in Relief.**—For the purpose of stamping your brass tickets you will require a steel die, which will have to be cut by a die engraver. The brass is then stamped in a machine made for the purpose. It is perfectly possible to strike them up with a hammer, but you would run a risk of injuring the die. Whoever makes them, you will have to pay for the die, although you will not get it unless an arrangement is made to the contrary. The press is always saleable, and can generally be bought second-hand.—Os.

[57029.]—**Turbine.**—Such a small quantity as about 25·823 cubic feet per minute would do but little for you. Very much would depend on the class of wheel, as the best ones only utilise about 80 per cent. of the gross power. To make a turbine would be a very difficult matter, as it means many calculations carefully gone through before the best form was found. It is not often I so advise; but, in this case, I believe you would do far best to buy one of a maker who makes a speciality of such motors. The necessary data could be calculated out; but it means going over a lot of ground.—Invicta.

[57031.]—**Soap Analysis.**—This is conducted as follows: 1st. Fat. Weigh out about two grams of the soap in a beaker, add distilled water, and warm until all the soap is dissolved, add a few drops of methyl. orange solution, and titrate with standard sulphuric acid until a pink colour is obtained; the mixture should be warmed from time to time. 2nd. Water. Weigh out about two grams into a flask and warm over a sand bath until the soap just begins to give out the peculiar pungent odour of burnt soap; then allow to cool and weigh again: the loss of weight is the water which the soap contains. 3rd. Fat. This, if the soap be pure, is best determined by difference, that is, subtracting the percentage of alkali and water found from 100. To determine the fat weigh out about five grams of the soap into a beaker, dissolve in warm water, add sulphuric acid until the water solution is distinctly acid, allow the mixture to cool, when the fat acids will collect on the top of the liquid; if these form a solid cake they can be washed by pouring off the water from them, adding distilled water, boiling up, then allowing to cool, again pouring off the water, adding fresh clean water, boiling, and then allow to thoroughly cool, when the fat cake can be separated from the water, dried between filter papers and weighed. If the cake of fat acids is soft or liquid, a weighed quantity of white wax should be added, and the acids washed and weighed as described, from this the weight of wax is subtracted, leaving the weight of fat acids. As thus obtained, the percentages of alkali, water, and fat will exceed 100, by an amount varying from 2 to 3 per cent., according to the character of the fat from which the soap has been made.—George H. Hurst, Salford.

[57033.]—**Refining Gold.**—Take the gold you wish to refine and melt it in a burnt bone crucible; this will extract the baser metals and leave only the gold and silver. Pass this piece through a flatting mill, then put it in a glass bottle containing nitric acid, and boil it over a small gas jet. This will extract the silver, thus forming nitrate of silver, and leave the piece of gold (now pure) in a porous condition.—A. A. E. Lecluse.

[57033.]—**Refining Gold.**—Break the articles up into small pieces, treat with excess of aquafortis (nitric acid), which will dissolve out the copper and silver, but leave the gold untouched. When the addition of fresh nitric ceases to act on the alloy, pour off the fluid, which contains all the copper and silver as nitrates, along with free nitric acid. The silver may be precipitated from this acid solution by placing in it a strip of clean copper. The copper will precipitate the silver as a black powder, which may be washed on a filter, dried, and redissolved in nitric to produce pure silver nitrate, or fused to reduce it to the reguline state. The gold may now be dissolved in aqua regia (nitro-hydrochloric acid), and evaporated till fit to crystallise, to produce chloride of gold.—S. Bottone.

[57033.]—**Refining Gold.**—Dissolve the alloy in nitro-muriatic acid with the aid of heat. The silver will precipitate itself as chloride of silver, and can be reduced to metal by fusing in a crucible with a mixture of the carbonates of soda and potash. To the clear solution which remains above the chloride of silver add a little sulphate of iron in solution; this will precipitate the gold as a black powder, which must be collected on a filter or at the bottom of glass, and (to make chloride) redissolved in nitro-muriatic acid, and evaporated to just the melting point. The remainder of the original solution can be rejected, as it now contains only copper. If you have sufficient gold to warrant all this trouble and expense, and are accustomed to chemical manipulations, by all means try it; but if neither one nor the other of these conditions obtain, sell your gold for what it is worth, and purchase the chloride. —Os.

[57033.]—**Refining Gold.**—To separate the silver and copper from gold of any quality, proceed thus: Melt the gold and granulate it, or roll it out very thin and clip it into small pieces. Put the pieces into a Florence flask containing nitric acid, with one-third water. Place the flask on a sand-bath, and apply heat till all fumes disappear. Pour off the liquid carefully, and add a little more nitric acid and water, and, if there be no further ebullitions, this proves that all the gold is separated. Pour off the liquid again, and the resultant mass at the bottom of the flask is pure gold. To make gold chloride, pour upon the pure gold thus obtained (which is still in the flask) nitric acid one part, hydrochloric acid two parts; place upon the sand-bath, as before, till the gold is all dissolved. Then pour the solution into an evaporating dish, and evaporate to dryness. The mass that remains is chloride of gold, which may be used for photographic purposes, or for electro-gilding. Great care must be exercised in evaporating to dryness, because if too much heat be applied the gold is re-formed into the metallic state, and the operation requires to be performed over again. To obtain the silver, place a plate of copper in the liquid that was first poured off, and the precipitate is silver. Then pour off the liquid carefully, and place a plate of iron in it, and the copper is thrown down. If all this is carefully done, not a grain of any of the metals is lost, as may be seen by weighing the alloy before beginning.—Bobadil.

[57035.]—**Bicycle Spring.**—I have made such a spring from the ordinary steel wire obtainable from the wire-drawers or wire-shops. You must bend it to shape at a dull red heat, not cold on any account, and be very careful not to overheat it. When to shape, having allowed the requisite amount for spring, harden the whole right out. Then temper to spring temper: and that is the difficult part. There is no difficulty to a good smith in bending into shape and hardening; but the tempering all over is quite another matter. I have for a similar job tried a lot of plans; but the best to suit me was an arrangement of sand bath; but at the best it is a troublesome job. Springs made by a first-class smith and tempered with the utmost care were nothing so satisfactory as the same kind bent to shape here and hardened and sent to Messrs. Salters to be tempered.—Invicta.

[57038.]—**Wimshurst Influence Machine.**—"Aurora" will find it quite possible to construct a multiple plate machine of this type. I already know of two machines, each with six plates. I should be glad to help him with any detail; but to comply with his request, and to give him the full details for a twelve-plate machine would be something beyond reasonable. He should either plan out the machine for himself, or he should, as a matter of business, engage some scientific instrument-maker to do it for him.—James Wimshurst.

[57039.]—**Firing Mines.**—Your coil is no use for this purpose. Get half a dozen small bichromate cells; these will make a piece of platinum wire red hot, and ignite your powder.—Os.

[57040.]—**Voltaic.**—An electric bell or a helix of wire wound round an iron core will demonstrate what you want.—C. D. R.

[57041.]—**Battery.**—Surely the querist does not call the Leclanché or Daniell small, or mean that powerful acids are required in them. These are the principal cells used for bells, telegraph, and telephone work, as they are constant in operation and require but little attention, and action only takes place whilst they are doing work. On the other hand, batteries that are suitable for large coils, lighting, and for motors, must be of a kind suitable to the work required, and, therefore, should generate a large amount of current with a high E.M.F. This cannot be obtained by the use of weak acid solutions and large surfaces. As the E.M.F. of a particular cell is the same be it large or small, there is no advantage to be gained in this particular by increasing its size. It is only the quantity of current that will be increased by the enlargement of the cell. If, therefore, a cell of small dimensions will give the desired E.M.F. and current, a larger will be wasting energy, in the same way that horse-power would be thrown away by employing two horses when one would do.—C. D. R.

[57042.]—**Spark Coil.**—This would require much more space than the query warrants. Several books are published on this subject. "Intensity Coils," by Dyer, price one shilling, will suit you.—C. D. R.

[57042.]—**Spark Coil.**—If anyone could stand a shock from your coil, the spark got from it must be so very small that few experiments could be successfully performed. Any experiments really worth trying must be performed with a coil which produces a spark of some length, and this means more shock than anyone could stand. I could help you with a few experiments if your coil has sufficient spark. What is its length?—Bobadil.

[57042.]—**Spark Coil.**—The experiments I have tried are not very varied, yet may suggest some others to you. I have, for instance, tried the effect of altering the surface and form of the discharging points, thus modifying the nature of the spark, or sending a spark over a partial conductor, and thus getting another form of discharge. Another was sending a spark through, or rather over, metal filings. The inflammation of ether was another; also of hydrogen gas. Then there is the electric cannon or pistol, and firing of gunpowder; whilst a detonating or series of thunderpanes afforded another experiment. I am afraid this is about all I can think of as being performable outside shocks and vacuum tube illumination.—Invicta.

[57044.]—**Silver-Plating.**—Use a Daniels' battery and a rather weak bath solution for German silver. You speak of cyanide of mercury: I suppose you mean nitrate of mercury. I never found it necessary to use anything of the kind. I wrote three long papers in these pages about two years since, if you have the back volumes.—Os.

[57044.]—**Silver-Plating.**—Articles of German silver should always be dipped in one of the mercury solutions before being suspended in the depositing vat. The coat of mercury causes the deposit to adhere. The simplest mercury solution to use is the nitrate, which is made by dissolving a small quantity of mercury in nitric acid diluted with three times its bulk of distilled water; and when the mercury is quite dissolved, diluting still more with water. The proportions of mercury and water in the prepared solution are, respectively, one ounce to one gallon. The articles which most require this solution are those of copper, brass, and German silver. They must first be thoroughly cleaned by being boiled in potash, then dipped in the mercury solution and kept in it till a coating of mercury appears, then washed and immersed in the depositing vat while still wet. The batteries you have been using seem to have been working satisfactorily; but for your purpose most authorities recommend a Smee or a Daniell.—Bobadil.

[57044.]—**Silver-Plating.**—If "A Beginner" tries the following solution I think he will succeed: —German-silver articles are first cleansed in boiling alkali, washed, then dipped in a mixture of two-thirds parts of sulphuric and nitric acids; then into a quickening solution, and from this into the plating bath, which, if in good order, should give good results. For a long time the following bath has held the place of acknowledged superiority for silver-plating. It is composed of: Water, 1,000 parts; cyanide of potassium, 50 parts; pure silver, 25 parts. This bath is prepared as follows:—A porcelain dish or capsule, of the capacity of a quart, receives pure granulated silver, 25 parts; pure nitric acid, 50 parts. The whole is heated over a charcoal furnace or gas-lamp, the dish being supported upon an iron triangle, and protected by a strip of wire gauze from direct contact with the flame. The acid rapidly attacks the silver with the production of abundant nitrous vapours, which one should be careful not to inhale. When the reddish vapours have disappeared, there remains in the dish a liquid more or less greenish, blueish, or colourless, according to the proportion of copper contained in the commercial silver employed, which is seldom entirely pure. The heat is then increased in order to evaporate the excess of acid, which escapes in the form of white fumes. The material in the dish dries, swells up, and with a further increase of heat, fuses like wax. The dish is then removed from the fire, and protecting the hands with a cloth, the fused mass is made to flow upon the sides, where it soon solidifies. We have thus obtained the fused nitrate of silver (lunar caustic), which is more or less white or grey, according to the purity of silver employed. When the whole is quite cold, the dish is turned upside down upon a clean sheet of paper, and by a gentle tap on the sides, the mass is detached. 2. The nitrate of silver is dissolved in ten or fifteen times its weight in water, and treated with a ten per cent. solution of pure cyanide of potassium, which immediately produces an abundant white precipitate of cyanide of silver. A sufficiency of the reagent has been employed when, after allowing the precipitate to subside, the addition of another drop to the clear supernatant liquid produces neither turbidity nor precipitate. The whole is then thrown upon a linen filter stretched upon a wooden frame, and the cyanide of silver remains upon the cloth, while the nitric acid and the excess of cyanide pass through. The precipitate left upon the filter is washed two or three times with pure water. 3. The cyanide of silver thus prepared is placed in the vessel intended for the bath, and stirred into the 1,000 parts of water prescribed in the formula. The cyanide of potassium is then added, which after solution, also dissolves the cyanide of silver. The silver bath is therefore ready for use, and is a solution of the double cyanide of potassium and silver.—JOHN T. DEWAR, Antwerp.

[57045.]—**L. and N.W. Compounds.**—The number of *Engineering* for May 1st, 1885, contained a full list of compounds. The following should now be added:—509, Ajax, March, 1885 (Crewe); 687, Himalaya, May, 1885 (Rugby); 2798, Marchioness of Stafford, 1885 (at present the Inventions Exhibition is where this engine is stationed, as I daresay "Cotswold" is aware). According to the attendant, its present high number will be changed on the engine commencing regular work.—L. N. W.

[57046.]—**L. and N.W. Manchester Express.**—Nearly always a 6½ft. four-coupled or "Standard passenger engine."—L. N. W.

[57049.]—**Dynamo.**—Can you send me a sketch of the arrangement of the field-magnets and pole pieces? I must confess I am considerably muddled by your explanation "that the field-magnets all bolt on one side of the pole pieces," and yet are "arranged in a circular form."—S. BOTTONE.

[57054.]—**Cleaning Stationary Boiler.**—To "INVICTA."—To keep such a boiler clean is a difficult job. If one asked many of the boiler-fluid vendors they would all offer a remedy; but these are not so reliable in use as in theory. With large tubular boilers I have had under my control we used nothing but ordinary carbonate of soda, or the common soda of every-day use, and we found that a moderate quantity was sufficient. Most probably about 1½lb. per day would be sufficient for your purpose. With the use of soda you would need to use the scum cock, and blow off frequently as well as at regular intervals, or the water will be found to thicken, and you would get into mischief. I should dissolve the soda and pump it in with the feed. Another point is never to blow all the water out of the boiler when she is hot. When you mean to clean out after stopping, blow off the steam quietly at the safety-valves, the fire being, of course, drawn, and let her cool down quietly. Next day let the water run out quietly; take off the mud doors, and the deposit will be found as a soft mud that very little washing with the hose will clear out. Too much soda will cause foaming, so do not err on that side. It is with a loco. type boiler I know a difficulty in keeping it quite as free from scale as one would wish; but a good feed heater would help you as well. When in the States I saw one very good form of boiler cleaner, the theory being that the scale was thrown down in the quietest part. That this was so the apparatus in question amply proved. It did not remove old scale, but no new scale formed, whilst bit by bit the old fell off the plates. If your feed is very bad, I should think it would amply pay to have a deposit catcher fitted—not on the usual bungling system, but on a really scientific plan, and thus keep the deposit out of the boiler altogether.—INVICTA.

[57055.]—**Electric Bells in Series.**—This appears to be a quotation from a description of something intended to be new, and therefore can best be answered by the writer. It sounds like a clipping from an advertisement.—C. D. R.

[57055.]—**Electric Bells in Series.**—This double winding of the coils was suggested by Jolin, of Bristol. I fail to see any advantage over the old plan of the armature short-circuiting the coils. To my mind it introduces complications in the way of resistances and counter-currents, without any compensating advantage; for instance, the cores should be of the softest possible kind, or there would be residuary magnetism, and the reversed or secondary coils would have to be exactly suited to their work, or the current would pass through without demagnetising. In that case, it would be simply the shunt circuit plan before alluded to, saying nothing of the extra expense of double winding.—G. J.

[57056.]—**Problem.**—I suggest that Mr. Fryer should turn his attention to something more scientific than the problem given. The existence of Adam is, to put it mildly, very doubtful, and the 6,000-year chronology is utterly discredited.—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[57056.]—**Problem.**—Might I suggest to G. Fryer another way of putting his question to himself? All those that are born die, therefore the population cannot increase at all. This is about on a par, so far as reasoning goes, with that contained in his query. Without going into the matter, I expect that he would find that the deaths in the last 200 years would more than equal the number of those now alive.—GARRISON GUNNER.

[57057.]—**Transmission of Power by Belts.**—Let

$T$ = tension in lbs.
$v$ = velocity in ft. per min.

$$T \times v = n \times 33000.$$

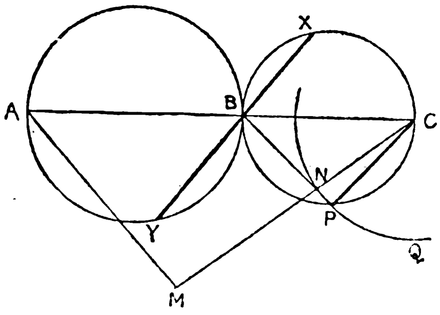
$$T = \frac{n \times 33000}{v}$$

$$v = \frac{n \times 33000}{T}$$

$$n = \frac{T \times v}{33000}$$

If this is not clear I will correspond with him, if he will publish his address.—S. S. N.

[57058.]—**Science Examination.**—Let the two circles touch at B, and draw the common diameter A B C. Draw from C a straight line C M in any direction equal in length to the given straight line. Join A M, and draw B N parallel to A M. With centre C and radius C N describe circle N P Q, cutting circle B P C at P. Join C P, and through B draw X B Y parallel to C P—X B Y is the line required. Proof: Join B P and C X, then the figure B P C X is a rectangle. ∴ B X = C P, and by similar triangles—



$$\frac{XB}{BY} = \frac{CB}{BA} = \frac{CN}{NM}.$$

Also $CN = CP$ (radii of same circle).
$\therefore CP : NM :: XB : BY.$
But $CP = XB$. $\therefore NM = BY$.
Hence $CM = XY$. Q. E. F.

—C. PLANCK.

[57060.]—**Theoretical Mechanics.**—A knowledge of the differential calculus is not absolutely necessary for the honours examination in this subject; but it is very desirable. The querist should study Yates's book, price 4s.—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[57061.]—**Platinotype Process.**—The price is about the same, but the results are far superior, more artistic, and absolutely permanent. The process is certainly much easier than ordinary silver printing.—S. BOTTONE.

[57061.]—**Platinotype Process.**—I began to work it before the Inventories opened, simply following the printed instructions sent by the company. The process is so extremely simple that I mastered it at once, and when I saw it at the exhibition I found that I had been doing it exactly right. The platinotype paper is rather dearer than the ordinary sensitised paper for silver prints, but the chemicals used—oxalate of potash and hydrochloric acid—are cheap, and one of them, the oxalate, may be used over and over again, whilst the acid is used but very sparingly. I can strongly recommend Mr. R. A. R. Bennett to become a licensee of the Platinotype Company, as the time saved by their process, and the beautiful and artistic results obtained by it are well worth the license fee and other small preliminary expenses.—J. GUARDIA.

[57061.]—**Platinotype Process.**—I would strongly recommend Mr. Bennett to try the platinotype process. I have been using it as an amateur for several months. There is a little difficulty at first in judging whether the prints have been sufficiently exposed or not; but when by practice this difficulty is overcome, the process is a most delightful one to work. The prints print much more rapidly than silver prints, and when the printing is finished and we proceed to development, the pictures are developed, cleaned, and washed in as short a time and with as little trouble as it takes to wash the silver from silver prints before putting them in the toning bath. On the whole, I do not think there is much difference in expense. The sheets of platinotype paper are 26in. by 20in., and are good up to the edge, and cost 1s. 4½d. each if bought by the quarter-quire. The developing bath can be used over and over again, and only one of the three clearing baths need be new for each batch of prints, and hydrochloric acid is very cheap.—T. PERKINS, M.A.

[57063.]—**Specific Heat.**—Let $x^\circ$ be resultant temperature of mixture. Specific heat of snow = 79—

$$\therefore 5\,(79 + x) = 25\,(30 - x).$$

$$\therefore x = \frac{5 \times 30 - 79}{5 + 1} = \frac{150 - 79}{6} = \frac{71}{6} = 11\tfrac{5}{6}^\circ$$

—T. H. L.

[57066.]—**Reducing the Amount of Lime in Chalk Water.**—Clark's process is founded on the fact that free carbonic acid in water dissolves carbonate of calcium. If, therefore, the exact amount of quicklime per gallon of water treated (to be determined by a preliminary experiment) necessary to absorb the carbonic acid is added to the water, the chalk so produced, as well as that previously held in solution, will be pricipitated; and, from the flocculent nature of the precipitate, the water will be at the same time filtered.—PI.

[57066.]—**Reducing Amount of Lime in Water.**—Chalk, or as chemists call it, calcic carbonate, or carbonate of lime, is almost insoluble in water, if it (the water) contains no free carbonic acid. Most waters do contain a considerable quantity of carbonic acid in solution. Lime has the power of absorbing carbonic acid, and forming with it chalk, or carbonate of lime; hence, if a little freshly-prepared milk of lime (slaked lime mixed with water) be added to water holding chalk in solution by means of carbonic acid, the lime seizes on this latter, and the chalk thus formed, along with the chalk originally contained, will fall to the bottom, when the clear liquid may be decanted off.—S. BOTTONE.

[57066.]—**Reducing the Amount of Lime in Chalk Water.**—The temporary hardness of water is due to calcium carbonate dissolved in excess of carbonic acid, probably forming some sort of a double carbonate. On the addition of lime to a water containing this compound the carbonic acid combines with the lime, forming normal carbonate, which, together with the carbonate already in solution, precipitates, and the water consequently softens. A quantity of milk of lime slightly in excess of that needed is mixed with the water, and allowed to stand twenty-four hours, the excess of lime being afterwards destroyed by adding more unlimed water. I believe the process is worked at Canterbury and Tring. It has, of course, no effect on the permanent hardness of the water, due to calcium sulphate, &c.—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[57066.]—**Reducing the Amount of Lime in Chalk Water.**—"C. H. D." has been correctly informed with regard to Clark's process of softening water, excepting that it is not a patented process. It is carried out as follows: the water to be softened is stored in large tanks, whose capacity is known; by means of a standard soap solution, as has already been described in the "E. M.," the amount of temporary hardness is ascertained, and from this the quantity of carbonate of lime in the water in the tanks; then milk of lime is added—this is made by slaking quicklime in water, using 56 parts of quicklime for every 100 parts of carbonate of lime in the water. The water is agitated during the time the lime is being added; it is then allowed to rest, when the precipitated lime settles to the bottom, leaving the softened water clear and ready for use. A patented modification known as the Porter-Clark process is in use in some places where the large storage capacity required in Clark's process is not obtainable. In Porter's process the water and lime are conveyed by pipes into a common pipe, in such proportions that the lime conveyed by one pipe shall be just sufficient to combine with the carbonate of lime in the water conveyed by the other pipe. The mixed waters carrying precipitated carbonate of lime are now passed through filters. I refer "C. H. D." to the *Journal* of the Society of Chemical Industry for February, 1884, for details.—George H. Hurst, Salford.

[57069.]—**Hot Water.**—The boiler specified by "Les Dents" is far too small for the required work, and gas would be an exceedingly costly fuel for so large an arrangement. A coil of 1¼in. iron steampipe, seven turns on a 9in. mandrel, used as an upright boiler, set in brickwork with grate bars 4in. below the bottom coil, would, if fired with coke inside the coil, do all that is required easily at a cost of one-tenth that of gas. To get at the cost of gas for the purpose, calculate the whole pipe and cylinder surface to be kept, say, at 180° Fahr., and allow one cubic foot of gas per hour for every 1½ square foot of surface. Add to this two cubic feet of gas for every gallon of scalding-hot water required during the day. For the cost of coke take the cost of gas at 3s. for 1,000 cubic feet and divide it by 10; this will give the approximate cost of coke at 4d. per cwt. The above rule is the result of 12 months' working of each of the two systems with a circuit of 80 square feet of radiating surface, kept hot continuously night and day.—T. F.

[57069.]—**Hot Water.**—Your hot-water boiler is altogether too small for the demands you make on it. The faults, so far, are that the heating surface is insufficient, and this is made worse by the great length of flow and return pipe. The hot-water cylinder should be as close to the boiler as possible, and I prefer, if it be possible, to place them in a cupboard by the side of the fireplace. The heating and storage of hot water does not as yet seem dealt with in anything like as scientific a way as many other things. I consider, for the length also, the ¾in. pipes are too small. The amount of heat lost in the length of pipe alone is considerable. Then the boiler, having no doubt the fire on the one side only, has little more than one half the heating surface it might make available. My remedy would be to increase the heating surface and the storage capacity, and at the same time I would in some way clothe the hot-water cistern, by either roughly lagging and filling up with sawdust, or some equally simple plan. By inference I understand that unless the fire be well kept up the temperature of the water rapidly decreases. This is bound to be so, as the storage capacity is so small that the volume of hot water, when the whole contents of the cylinder are hot, would very quickly be exhausted, this being increased by the cooling of the water due to passing through a long length of small pipe. To get a plentiful supply of hot water, a good and steady fire must be kept up, and even then there must be ample storage.—Invicta.

[57070.]—**Telephone.**—As you say that the telephones give a click on being connected with a battery, there should be no difficulty in getting them to act properly, provided you get the right adjustment. Of course, I need not tell you not to use a battery with them for actual work. Screw up the magnets until they just touch the diaphragm—this you can tell by the peculiar tubby noise given on tapping with the finger nail. Now screw back until the magnets just clear the diaphragm: this is the best position. Be sure to put your ear close against the bell of the mouthpiece, and be sure also to place the speaker at such a distance that you cannot hear his voice direct when he speaks. No. 40 wire is very fine, No. 30 would have been better.—S. Bottone.

## UNANSWERED QUERIES.

## QUERIES.

◆◆◆

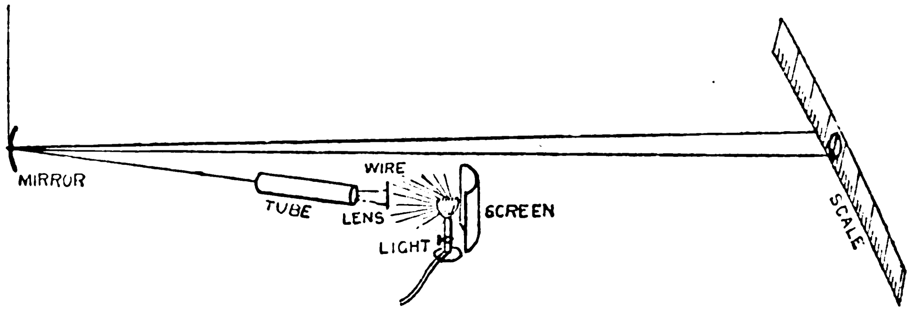
[57072.]—**To Mr. Bottone.**—It is the armature of the Siemens-Alteneck pattern that I should like a description of. Many thanks for your reply.—Accumulator.

[57073.]—**To Mr. Rogers.**—Many thanks for your reply to my query concerning the am-meter, but the kind of instrument you describe is of no use to me. I am in want of a more substantial instrument that will stand moving about. I should be very much obliged if you could give me any further information concerning my query.—Accumulator.

[57074.]—**Lens for Mirror Galvanometer.**—Can any of our optical correspondents give me a few hints about the proper lens to use for a Thomson mirror galvanometer? When working with the lamp and scale at the common 3ft. distance from the mirror it is easy enough with a little dodging to get a reasonably bright ½in. spot and clear line, with almost any lens (convex). When working, however, as I always prefer to do, with the scale some 15ft. to 20ft. off, and a 3in. spot, it is by no means so easy; in fact, the amount of dodging required seems to vary as an unpleasantly high power of the distance. What I want, in short, is this:—1. Given *a* the distance between the lamp and mirror, and *b* that between mirror and scale, what focus lens will give a good bright spot *c* inches diameter on the scale, and what distance should the lens be from the lamp? N.B.—The mirror is generally figured—*i.e.*, concave; what is the advantage of this, and how is it to be allowed for in the above? 2. A sharp black line is required across the spot. At the 3ft. distance, it is sufficient to paint a fine line on the lens itself, but for long distances this does not seem to answer. What is the correct distance (in terms of focal length, &c.) at which a wire should be stretched behind the lens to give a sharp black line on the spot? If it would take too long to get out a general solution to the above question, perhaps someone would give one for the following data?—

Lamp to mirror ...... 6ft.
Mirror to scale ......... 15ft.
Foc. length of mirror 18in.
Diameter of spot tube 2in.

In case anyone has forgotten the arrangements of mirror, I add sketch.—C. G. S.



[57075.]—**Parchment Paper.**—Will someone oblige by giving plain directions to make the above, and the best kind of paper to use? I want to use it for jam pots and honey bottles?—Turtle Dove.

[57076.]—**Fire, Acid, and Moisture-Proof Card.**—Some friends of mine require for a particular purpose a fire-proof, acid-proof, and moisture-proof cardboard, or other material in thin sheets, and at an expense of not more than 2d. or 3d. per square foot. Can any of your readers tell me whether such a material is obtainable?—J. H. Collins.

[57077.]—**Boracic Acid.**—Is this substance perfectly harmless when used for preserving articles of food, such as milk, butter, soups, &c.? Will it also prevent fermentation in infusions of tea and coffee and juices of fruit? Kindly say what quantity should be used. Is there anything better than this for the purpose? Is it expensive?—Agricola.

[57078.]—**Incubators.**—I have made an incubator for batching chickens, and am at a loss for a regulator to keep it at one heat, from 102 to 105. Will someone that has had experience in such kindly answer and tell me the best way to make one?—D. Blake.

[57079.]—**Windway.**—I have a two-row Monro tube board; I intend only to use three and a half octaves. Will Mr. Fryer, "Organon," Mr. Wenham, or any other kind friend tell me how I can use it for paper valve? Can I build on it, so that the paper will pass over the holes outside, and not under as in the orguinette. Can I cut off one row of reeds at pleasure. A rough sketch will greatly oblige.—A. B. C.

[57080.]—**Siphon.**—Would any of "ours" give the reason why a siphon constructed under the following conditions does not flow continuously, but after being started works well enough for a day or two, and then gradually weakens, until on or about the fourth day it stops entirely? The supply is from a well containing 12ft. of water. The pipe is a 1in. lead, and has its inlet at the bottom of the well, 12ft. under water. Starting from the well, there is a gradual rise, till at a distance of 220 yards, the pipe passes over a summit 21ft. above the bottom of the well, and then descends, and at a distance of 500 yards from the summit it reaches foot of wall of house, with a fall of 51ft. below bottom of well. The pipe then passes up 15ft. inside the house, and terminates thus in a ball cock, 31ft. above bottom of well. The summit is situated at 750ft. above sea level. Granting that silt is kept clear, and with a sufficient supply of water, what causes the stoppage?—Surveyor.

[57081.]—**Watchmaker's Bow.**—Thanks to "Escapement" for his answer to my query last week, and will he tell me how to make a good bow for driving turns, as I cannot make them drive as I should like?—Lever.

[57082.]—**Hydraulic Leather Collars.**—Will some kind reader inform me how to calculate the amount of power absorbed by cup leathers working in iron cylinders? Please do it by simple arithmetic.—G. B. B.

[57083.]—**Freemasonry.**—Will some of your readers who are freemasons kindly say whether the benefits of being one are equal to the great expense?—Z.

[57084.]—**Shunt Dynamo.**—To Mr. Bottone or Others.—Seeing that a shunt dynamo is built up of soft iron cores in the field magnets, from whence and how is the first initial current generated to excite these magnets? I find that I may run the armature of a shunt dynamo for an indefinite time, yet no current or signs of magnetisation till the brushes are brought into contact with the commutator. Does the first generation of current start with this friction? If not, how is it generated?—W. B.

[57085.]—**Heating Surface of Vertical Boilers.**—Will those readers who possess vertical boilers kindly note the arrangement of tubes or flues, the heating surface, and the grate area, and the indicated horse-power of the engine driven? Please give, also, the pressure of steam in the boiler, and, if possible, the water pumped into boiler per hour; and say if there is a natural draught or a blast? I want to collect data as to the heating surface required for this class of boiler, and shall be much obliged to those who will give their experience. If nothing but the heating surface, indicated horse-power, steam pressure, and kind of blast is given, those particulars will be of great use.—Glatton.

[57086.]—**Colliery Warnings.**—To T. J. Murday.—From what data do you know that the dates you name on page 412 (No. 24448) will be highly dangerous to miners?—Ralph.

[57087.]—**Spirit Varnish and Polishing.**—Would some readers kindly say how to make spirit varnish (good body and hard)? Also, quickest method of polishing native timber—elm, beech, &c.?—A Working Man.

[57088.]—**Emigration.**—Will any reader kindly say whether Australia, New Zealand, or Western States of America offer the best opening for a furniture manufacturer on a small scale?—An Anxious One.

[57089.]—**Electric Cement.**—Can anyone tell me of a good electric insulating cement that will stick to glass and metal, will not be affected by moisture or temperature of, say, 150deg. C., can be applied cold, and will not expand or contract much on setting?—Stud. Inst.C.E.

[57090.]—**Copper and Zinc Polishing.**—Will some reader of the "E. M." kindly inform me the best way to face zinc and copper plates ready for etching?—W. M., Bolton.

[57091.]—**Coating Cast Iron.**—What is the best material to coat cast-iron machinery with, so as to resist the fumes of sulphurous acid?—J. S. D.

[57092.]—**Ginger Beer Plant.**—Can any of your correspondents give me any information respecting the ginger beer plant? What is its correct name? To what tribe does it belong? How is ginger beer made with it? Is it perfectly safe and harmless to drink?—Rushallite.

[57093.]—**Beam Engine Slide Valve.**—Engine 6ft. 6in. stroke, diameter 28in., 22 revs. per minute, slide valve 14in. long, 14½in. wide, exhaust 8in. long, steam ports 2in. long, exhaust port 4in. long; has been working with a travel of 6½in., which I have shortened to 5in. of travel. I don't think this valve is anything like what it ought to be; I should think it ought to be at least 1in. longer, and if it was made longer I suppose the eccentric would have to be put faster? If the valve was made 1in. longer and the eccentric put forward, how would it affect the exhaust? Would it be of any use to lengthen the valve, or must I, to get an earlier cut off, have a new valve? It appears to get steam almost, or quite, the whole of the stroke. With steam at 35lb. per square inch, non-condensing, what power ought I to get?—J. G., Bristol.

[57094.]—**Eccentric on Shaft.**—To "Regulator."—I advertised my address as requested in "Ours" of July 3rd, and should be glad to receive the information promised.—S. S. N.

[57095.]—**Photography.**—To Mr. Lancaster.—I am about constructing a small camera, according to your instructions in No. 953, Vol. XXXVII., of the "E.M.," and should feel obliged if you would enlighten me on the following points. 1. Am I right in presuming that the width of the body, when finished, is to be exactly 4½in.? As in that case, the two shorter of pieces of wood would require to be 4⅛in. long, instead of 4⅝in., as directed. 2. How is the focussing slide attached to the back of the camera? I suppose the ground glass must be fitted in a frame. 3. What is the construction of the dark slide, and how is it adapted to the back of the camera? In all the cameras I have seen, the dark slide is pushed in from the top, and slides in grooves in the sides.—Amateur.

[57096.]—**Covering Electric Light Cables with Lead.**—Can any of our readers tell me how this is done, and what kind of a machine is used to do it, and also the plan of the machine, the lead must be no thicker than 3-32 of an inch?—Anxious to Know.

[57097.]—**Tinning Copper Wire.**—I have several miles of small copper wire to tin, I wish to know how this is done, whether the coil is dipped in at once, or passed through singly, also the kind of acid used, and all particulars? The wire is required for electrical purposes.—ANXIOUS TO KNOW.

[57098.]—**Warehouse Lift.**—Would a reader who has a thorough knowledge of lifts, be kind enough to give a plan sketch of a lift, to raise 5cwt. to the height of 35ft. through two floors of a warehouse, and whether a gas engine would do the work, stating the h.p. required, and probable cost including fitting up, and at what rate the lift will travel?—W. J. D., 55, Albyn-road, St. John's, S.E.

[57099.]—**Watchwork.**—To "C. A. W."—I am extemely obliged to "C. A. W." for his hints on polishing, in reply to my query (56972). If it is not giving too much trouble on so small a matter, may I trouble him still further? I have been using red stuff, and only lately tried diamantine, and do not know how this is used. If he will say how this is mixed for use, shall be obliged.—ESCAPEMENT.

[57100.]—**Spectroscope.**—Will some friend who has technical knowledge of this beautiful instrument, inform me if a combination of five prisms, gives enough dispersion to view the red solar prominences with, or is it worth while attaching so small a spectroscope to an astro. telescope.—E. B. F.

[57101.]—**Spectra.**—When I look at a piece of blazing paper with a spectroscope, I see the D line conspicuouly displayed, particularly if I have taken the trouble to shake a pinch of common salt or soda over the paper before setting it on fire. I want to know of a few other experiments, by which I can show in a correspondingly simple manner, the spectra of other substances. I do not care what those substances are, if the experiments are as easy and striking as the exhibition of the D line.—E. B. F.

[57102.]—**Air and Fuel.**—There is one matter in regard to the combustion of fuel, which I cannot understand, and on which I wish to be enlightened. How is it that the enormous pressure of the air does not cause itself to be forced into fires with greater effect, considering the great effect produced by the simple blast of a bellows?—VULCAN.

[57103.]—**Analysis of Copper Wires.**—To MR. W. J. GREY.—I have to test the purity of copper wires from three mils to twenty-five mils, our standard being 96 per cent. This is done electrically; but if the process is not too elaborate, I would rather take the analysis, so as to check one process with the other. Thanks for your kind attention.—EXPERIMENTER.

[57104.]—**Actuarial.**—Will some actuary kindly tell me what half-yearly payment I should receive for thirty years, by sinking £100, calculating interest respectively (compound) at 3½ per cent., and 4 per cent.?—ANNUITANT.

[57105.]—**Street Coil.**—I am about making a coil on the same principle, I believe, as is advertised by King. Mendham, and Co., Bristol; would any of "Ours" kindly assist? A rough sketch would very much please. The base is to be 3ft. by 2ft., upon this a small raised platform; on the base, three pairs of handles, and upon the platform, the bobbin, contact breaker, set of two bells, and a switch for five powers. 1. What size should the bobbin be? 2. How much primary and secondary and sizes? 3. How to make up the connections for the bells with the oscillating hammer between, also for switch contact breaker, and handles? I should also like to have two studs for stopping contact breaker at will, and another for the bells; the wire connections should be all out of sight, and also the bells' electro magnets. I intend using a tube of brass for regulating the power, and the machine to be strong enough that the three strongest persons cannot hold its fifth power out, and providing they all take hold the same time.—YOUNG ELECTRICIAN.

[57106.]—**Galvanised Iron Pipes.**—A certain quantity of these having been laid down to conduct spring water, it is found pipes become coated in interior with a white substance; also after boiling water in a kettle, there is a white appearance. The water at spring has been analysed, and pronounced pure. What is this white deposit, what its cause, is it injurious, can it be obviated?—B. O. D.

[57107.]—**Developing Formulæ.**—In mixing chemicals for photo. purposes, would the solution be correct if I were to weigh the ounce of water by the same ounce as I use for dry chemicals, and will all developers require the same exposure? For instance, if a plate be exposed, and developed with the sodic sulphite, and exposure found to be correct, could good results be expected by giving the same exposure, and using any other developer?—JAY WHY.

[57108.]—**Home Practice for Bicyclists.**—Will any of your numerous readers give me directions how to make home trainer for bicycle to fix into?—A MECHANIC.

[57109.]—**Focus of O.G.**—Many thanks to "Rob. Crvs" for answering No. 56847. I do not intend to make the o.g., because I couldn't, but I have given an order for one of 3in. diameter, and the lens maker has asked me which focus would I like, 40 or 50in. If "Rob Crus," or "Invicta" would be so kind as to correspond with me, I shall deem it a favour.—FOCUS.

[57110.]—**Dynamo for Electro-Plating.**—Could any of your numerous correspondents inform me if it is practicable for an amateur to use a small electric dynamo, driven by hand or foot, for electro-plating on a small scale? If not, could they recommend me a permanent battery, that would continue to act for a lengthened period without replenishing, or one that would require very little looking after, and give me instructions for using same?—AMATEUR.

[57111.]—**Is the Earth a Conductor?**—As it is evident that one of the following questions must be misleading, and many of us who have but an elementary knowledge of electricity are unable to determine, will you or some of your readers kindly reply? First, is it really necessary to use a second earth plate for the completion of circuit of one battery whose terminus is buried in the earth? I should say no; but according to the teaching of some, one is asked to believe the reverse; for instance, Silvanus P. Thompson in his "Elementary Lessons on Electricity and Magnetism," page 404, Art. 424, not only gives a sketch, but declares the current, after having performed its work, enters the earth by means of earth plate, and travels back by the earth to the battery whence it started. Second, can the earth in any case play the part of conductor; is it not rather a receiver or dissipator?—LABOURER.

[57112.]—**Wet Plate Photography.**—Will some of "ours" kindly tell me where I can get a book containing full instructions for this process, stating price? Also, which is the easiest for an amateur to master, wet or dry, for portrait work, and will dry plates keep any length of time?—JAY WHY.

[57113.]—**Photography.**—Can any of "ours," who have tried various plates and developers, recommend a better make for an amateur for portrait work than Fry's and their sodic sulphite? At one time I got on fairly well with these; but my plates now turn a very curious colour when finished, and so are useless.—E. T.

[57114.]—**Cylinder for Reservoir.**—Will Mr. Davies, or any other practical reader inform me what thickness is necessary for a 7ft. cylinder (cast iron) flanged inside for sinking down well for reservoir about 25ft. deep (in about 5ft. lengths)? What is about probable cost per ton?—G. W. B.

[57115.]—**Faulty Telephone.**—I have made a pair of telephones of the following parts: Magnets 4in. by ⅜in., each magnet wound with about ½oz. of No. 36 silk-covered wire, and a pair of ferrotype plates 2¼in. in diameter. After fitting together and connecting up to about 12yd. of double wire, I could not hear the slightest sound when spoken into the one at the farther end. Do you think it would be better for me to rewind the bobbins with a finer wire, say, 38 or 40, and use larger and thinner plates? I forgot to say that when I connected up the ends of one of the telephones with the secondary terminals of a coil and set it in action, I could hear as well as feel the vibration in the telephone similar to that made by the coil. Any suggestion to put me right will oblige—MYSTERIOUS.

[57116.]—**Bell Telephone Circuit.**—To MR. S. BOTTONE.—What I wish to know, query 56990, is how to connect up a Bell telephone and microphone with a similar telephone and microphone at another station, only using two line wires (no earth return), and making one battery serve for both stations? If a small coil be necessary, where is it to be inserted; and how are the ends of the primary and secondary wires connected up? I am sorry for asking you so many questions.—TRANSMITTER.

[57117.]—**East Coast Express.**—Can any railway reader say if the 8 p.m. from King's Cross makes any stop between Newcastle and Edinburgh for water or otherwise? Bradshaw gives none, but it does the same with the 7.40 a.m. Caledonian train from Perth to Aberdeen, whereas that train stops at Forfar.—ABERDEEN.

[57118.]—**Paper Caps for Toy Pistols.**—Will anyone kindly tell me how to make them?—A. B. J.

[57119.]—**Herb Beer.**—I would be greatly obliged if any reader of the "E. M." would tell me how to brew and prepare for drinking tonic herb beer?—OLD SOLDIER.

[57120.]—**The Equation of Light.**—In none of the astronomical books I have is there any description of the method of calculating the correction due to the progressive motion of light in the case of, say, the eclipses of Jupiter's satellites, or the minima of Algol. I have myself worked out the following method of calculating the necessary correction, and would be obliged if "F.R.A.S." would kindly say if the method is a correct one? Knowing the right ascension, and north polar distance of the planet or star, and also of the sun at the moment of observation, we can, having two sides (the polar distances) of a spherical triangle, and the included angle (equal to the difference of the right ascensions) calculate the third side, or the angular distance between the sun and the planet or star. Then the natural cosine of the supplement of this angle (which will be the angle subtended at the sun by the earth and planet) multiplied by the time occupied by light in passing from the earth to the sun (say 8·3 minutes) will give the necessary correction, to be added to the observed time, if the cosine is positive (*i.e.* when the supplement is less than 90deg.) and subtracted if the cosine is negative. The result will give the heliocentric time of the observed phenomenon.—LIGHT.

[57121.]—**Mountain Snow.**—What is the reason the tops of mountains are covered with snow, while the heat of the sun is intense?—IGNORANT.

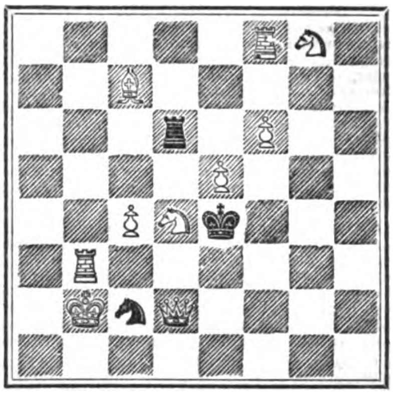
**Experiments with Terpine and Terpinol.**—At a recent meeting of the Société de Thérapeutique, Dr. Dujardin-Beaumetz recalled the fact that in treating turpentine with an alkaline carbonate a substance is obtained to which the name of "terpine" has been given. This substance has been experimented with by Dr. Lépine, of Lyons, who ascertained that it is endowed with very marked diuretic properties, and that it modifies the bronchial secretion in old catarrhal affections. Dr. Dujardin-Beaumetz has since experimented with a derivative of terpine—namely, terpinol, which is obtained by reacting on the former with sulphuric acid. Terpinol is described as being an oily substance, having an odour of jasmine, and being but little soluble in water. Dr. Dujardin-Beaumetz prescribes it in the form of pills as follows:—Terpinol, benzoate of soda, of each sixteen grains; powdered sugar q.s.; to be divided into ten pills, of which as many as ten can be administered daily. Terpinol is eliminated almost exclusively by the air passages, and gives to the breath a strong odour of jasmine. It exercises its action principally on the bronchial secretions, which it rapidly fluidifies.—*Lancet.*

## CHESS.

ALL Communications for this department must be addressed to J. PIERCE, Langley House, Dorking.

### PROBLEM DCCCCXLIX.—BY "PHONO."

*Black.*



*White.* [10+3

White to play and mate in two moves.

SOLUTION TO 947.

| *White.* | *Black.* |
|---|---|
| 1. Q-K B 8 | 1. Anything |
| 2. Q or Kt mates | |

(Ten variations).

### NOTICES TO CORRESPONDENTS.

CORRECT solutions of 946 from F. O'N. H., T. L. Robins, A. A. E. Lecluse,, and V. S. Pochin.

To 947 by V. S. Pochin, T. L. Robins, F. A. V., E. Stanley Follwell (interesting and pretty), Rev. W. Anderson (Old Romney), R. A. Bennett, and N. and F.

To 948 by Rev W. Anderson (but not second move in main play).

"E. M." Tourney game between Messrs. J. H. Blake (White), and W. Nash (Black).

(French defence).

NOTES BY MR. J. H. BLAKE.

(*a*) THE correct line for Black to adopt is to try and break through on the Q side before White has had time to make his attack on the other wing: 14. $\frac{\quad}{P\text{-}Q\ B\ 5}$ 15. $\frac{B\text{-}B\ 2}{P\text{-}Kt\ 5}$ would be good for that purpose.

(*b*) In order to block the Q side by P-Q Kt 4, in case Black now advances his Q-B P.

(*c*) Too late; White does not care about that side now.

(*d*) If 23. $\frac{\quad}{Q\text{-}R\ 2}$ 24. Kt-Kt 5 wins two pawns at least

(*e*) Taking with K P would be better, but White then wins the exchange and a P by Kt-R 4.

(*f*) There is nothing to be done if 25. $\frac{\quad}{R\text{-}Kt\ 3}$ 26. $\frac{Kt\text{-}B\ 6}{R\ \text{takes}\ Kt}$ 27. $\frac{Q\text{-}R\ 4}{\quad}$

THE American Government have forwarded a consignment of catfish to the National Fish Culture Association with a view to their being acclimatised to the waters of this country. They arrived per s.s. *Britannic* in perfect condition, all being alive, which, considering the long voyage they had been subjected to, is remarkable. The catfish is said to be a very valuable food-fish, and would assume a high rank amongst the freshwater fishes of our waters if cultivated; but anglers, or many of them, have great objections to the fish, which they say is destructive to nearly all others.

**Every Workman** connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS." published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade: to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling Twenty-four Words, and Sixpence for every Eight Words after.

## ANSWERS TO CORRESPONDENTS.

⁂ *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

### HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, July 22nd, and unacknowledged elsewhere :—

R. C. Moore.—Sanitas Co.—W. Wray.—R.—R. Hughes.—B. H.—Hemisus.—C. W. Bourne.—S. R. Bottone.—Bobadil.—A Fellow of the Royal Astronomical Society.—J. E. Gore.—Dr. Royston Pigott.—Fra. Broadbent.—P. E. W.—T. H. Hall.—Accumulator.—Bunsen.—No Chill.—M.I.C.E.—H. L. C.—Norfolk.—F. A. R.—James Stevenson.—B. S. T.—W. H. Eaves.—Werdna.—Young Farmer.—H. B. F.—James McCash Govan.—Farmer.—G. D. Seaton.

Novice. (Without more complete details of the purpose for which it is required, we can only suggest that one of the mercurial amalgams would be suitable—mercury and tin, for instance, which combine in all proportions. Mercury 10, tin 1, remains liquid, but equal parts soon become solid. How would that do? You must procure what is called grain tin, or else melt tin and pour it into a bucket of water so as to give it a slight fall from the ladle to the water.)—A. Tamer. (We do not know how electricity is used to tame wild animals, nor where to get the appliances.)—An Old Subscriber, Hereford. (We do not know that there is one in that district. There is a cable station at Porthcurnow.)—R. Gardiner. (You should apply to the captain of the Steam Reserve at one of the Government dockyards.)—Bazaar. (The "optical illusion" Thauma was described in No. 1024, p. 226.)—Thos. H. Purves. (You can obtain a copy of the patent rules from the Sale Office, Cursitor-street, Chancery-lane, W.C., by addressing Mr. H. Reader Lack, and inclosing 6½d.)—A Constant Subscriber, Indigestion. (The best way would be to consult a medical man, in order to ascertain what is the matter. If indigestion, see that heading and Dyspepsia in back volumes—pp. 503, 506, 529, Vol. XXXV.; pp. 262, 594, 620, Vol. XXXIV.; pp. 466, 513, Vol. XXXIII., and so on.)—Young Beginner. (See back volumes, or any of the guides to the lathe. A 6in. lathe means one in which the centres are six clear inches from the bed, so that work 12in. in diameter can be revolved in the lathe.)—Dulcimer. (Directions for making a dulcimer in Vol. XXXVI. pp. 97, 168; see also Nos. 160, 234, and 522.)—Klinkerfues. (The Klinkerfues hygrometer, which we imagine is the instrument you mean, was illustrated and fully described in No. 963.)—W. E. Lilly. (The best plan is to get a berth as engine-room artificer, and go to sea for one year; then, as you are an engineer, and have had, we presume, three years in the shops, you can sit for the examination, and obtain a certificate. Procure the "Engineers' Handbook," Reed and Co., Sunderland, which will give all particulars, examination papers, &c.)—J. E. Stocks. (The only method of cold brazing that is worth anything at all was given on p. 81, No. 888.)—W. H. (The only reply, besides recommending you to consult a medical man, would be to poultice, bathe, &c. Try frequent washing with permanganate of potash solution, and wear a bandage of pure indiarubber.)—Cyclist. (See the papers on nickel-plating in Vol. XXXVIII. pp. 44, 69, 111, 136; and Vol. XXXIX. pp. 96, 117, 133.)—Pluto. (It might be lumbago or disease of the kidneys, but if it comes on only after standing, it is probably nothing particular.)—D. C. (The *Dyer*, 9d. monthly, 3, Westminster-chambers, S.W.)—P. O. Lineman. (The English Mechanic telephone was described in No. 594, a number long ago out of print. It was disclaimed, and can therefore be used. It consisted of a membrane diaphragm with a piece of steel in the centre, which was attracted by a magnet.)—Virago. (The prior date would protect you; and if the inventions really were identical, both applicants would receive notice from the office.)—M. A. E. (Look through the indices. Described many times. 2. We do not know of such a work.)—F. L. R. (There is no such work. It would fill many volumes.)—A. Boydell. (Why not try? The answer is, Yes, up to a certain amount.)—Little Dorritt. (Can you not find what you require in previous replies about dynamos?)—A. Lowe. (Do you mean bronze powders, or a process to act on the metal. If the latter, it is surely necessary to state of what metal the medal is composed; but you will, no doubt, find a suitable method in back numbers.)—Uncle Rob. (Yes, we believe so; but forget the name of the agent. Apply to the inventor himself through his publishers.)—Beaconsfield. (Do you mean simply a case surrounded by ice, or a refrigerating machine? If the former, you can easily find several patterns at the dealers. They are simply boxes lined with zinc and fitted with ice-chambers.)

G. H., H. S. H., Hemisus, C. W. Bourne, and B. H. B. have replied to queries already similarly or adequately answered.

## USEFUL AND SCIENTIFIC NOTES.

**A Fire in a River.**—A Glasgow newspaper publishes the following:—"The singular sight is at present to be witnessed of a fire issuing from the waters of the river Clyde, a few hundred yards below Bothwell Bridge, and it has attracted to the scene thousands of curious spectators. For some time back, near the mouth of the Auchinraith burn, and not far from the left bank of the river, the water has in one or two places been seen to bubble up, the largest of the agitated parts marking a circle nearly a foot in circumference. Still no heed was taken of the circumstance until Thursday last, when an angler, while wading in the stream, which, owing to the dry weather, is abnormally low, scratched his match to light his pipe, and on throwing it from him the water at once caught fire and emitted a brilliant flame. It is now clear that the gas issuing from the mineral workings underneath is finding its way through a fissure in the strata to the surface of the water, and had been kindled by the lighted match. The boys amuse themselves ineffectually trying to put out the tongue of flame, which at night, it is seen, rises to a height of four or five feet, with branches of trees. A miner succeeded in extinguishing it with a flat stone, but it was at once re-kindled. Such occurrences, though rare, are not unprecedented in Lanarkshire. In 1829, and for some successive years, the gas issuing from the limestone rock on the property of Holms, in Cadder parish, rose through the earth and even the water on its surface. It was easily kindled with a match and burned brilliantly on the surface of the water. At the time of the first Blantyre explosion it was noticed as a curious fact that about 20 years before a bore was made above the fatal workings to a depth of 80 fathoms, when a jet of gas burst up, which on being lighted continued to burn for some time. Again, eight years later, when another bore was put down about the same spot at a much greater depth, the gas issued through the aperture, and after being kindled burned for weeks."

The Queen has granted a pension of £70 a year to Mr. Llewelyn Jewitt, the author of many antiquarian and topographical works.

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words .. .. .. .. .. .. .. .. | 2 | 6 |
| Every additional eight words .. .. .. .. .. | 0 | 6 |

Front Page Advertisements Five Shillings for the first 40 words, afterwards 9d. per line. Paragraph advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

|---|---|---|
| Twenty-four words .. .. .. .. .. .. .. | 0 | 3 |
| For every succeeding Eight Words .. .. .. .. | 0 | 3 |

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. | d. |
|---|---|---|
| Sixteen words .. .. .. .. .. .. .. .. | 0 | 6 |
| For every succeeding Eight words .. .. .. .. | 0 | 6 |

⁂ It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday, to insure insertion in the following Friday's number.

## TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve months, Post Free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII., XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., and XL., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

**Holloway's Ointment** may be relied upon in cases of inflammation or irritation of the internal mucous membrane. When this Ointment is diligently rubbed upon the back and chest, it relieves shortness of breath, fluttering of the heart, stitch in the side, cures colds, asthma, bronchitis, and protects the delicate against consumption.

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a Pink Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words, and 3d. for every succeeding 8 words.*

**Good Value Offered** (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—Caplatzi, Science Depot, Chenies-street, near British Museum. Established 1862.

New £18 **Operatic Musical Box**, 6 airs, select, richly inlaid Zither, patent winder, inlaid glass lid, all improvements. What exchange?—Seel, George's-road Bolton.

Iron Grand £60 new **Piano**, by Grunow, all improvements, including voix celeste, treble; bronze medallion front, walnut, £28. What offers?—Seel, George's-road, Bolton.

American walnut 280 dollar new **Organ**, two new swells, 12 stops, &c., all improvements, five years' warranty, £30, part exchange.—Seel, George's-road, Bolton.

Eight Original **Oil Paintings**, signed Slater, artist; grapes, &c. Approval with pleasure. New frames, English gold; choice. What exchange in clothes?—Address above.

Exchange **Bench Lathe**, 4½ centres, removed for larger; iron bed, tap for chuck fitting; with or without face-plate, or Foot Motor.—Linscott, Ramsgate.

Gregorian **Telescope**, 4in. mirror, two small ones, two eyepieces, brass table stand, all perfect. What offers?—Linscott, Ramsgate.

"**Imperial Lexicon,**" 2 Vols.; "Animated Nature," 2 Vols.; "Cassells' Popular Educator," 6 Vols.; "Technical Educator," unbound; equal to new. Exchange wanted.—W., Church-lane, Bridgnorth.

Some Conjuring, Electrical, and **Musical Apparatus**. I will exchange for gas bags, or small incandescent lamps.—Jones, 98, Packington-street, London.

Eight 9in. **Horseshoe Magnets**, also Pocket Battery. What offers?—B., 6, Broad-street, Spalding.

Handsome **Pipe Organ**, 7 stops, 1½ octave pedals, hand and foot blower; suit chapel; room wanted. Exchange American Organ or Piano.—Wales, Hemsworth, Yorkshire.

Large **Electric Bell** and three Leclanché Batteries 4¾in. gong. Full particulars on receipt of 1 stamp.—12, Old Park-road, Wednesbury, Staffordshire.

A splendid double-barrel **Gun**, all complete, with machines, to be exchanged for a 4 or 4½ centre Lathe; iron bed preferred.—Address, T. Bullock, 169, John-street, Workington.

44in. Humber type **Tricycle**, half plated, new this year, cost £27. Exchange for good screw-cutting Lathe, 6ft. bed.—Crocker, 51, Sutherland-road, Bow.

Wanted, a good **Camera**, Instantograph preferred, dry process. Exchange, and part cash to value.—K., 33, Essex-street, Reading.

Sweet-toned **Musical Box**, nearly new, cost £4 4s., plays 6 airs, inlaid. Wanted, useful exchange.—E. Halkyard, Rochdale-road, Milnrow.

Exchange 2 H.-P. **Vertical Engine**, with pump and pulleys, complete. Wanted, good tricycle frame, water motor, circular saws, or offers.—Wm. Poate, Havant, Hants.

Wanted, small treadle **Printing Machine**. Will send list of goods offered in exchange.—Apply, *Herald* Cardigan.

**Dynamo**, 800 c.p., 2cwt., nearly ready for wiring, with all fittings, lamps, &c. Exchange for a good 4 or 5in. centre back-geared lathe, iron bed and slide rest, or offers.—C. H. Hatch, Alderley Edge, near Manchester.

**Saw Bench**, 10in. by 6in., 4in. saw spindle, pulley, complete; Model of Beam Engine, near finished; 32in., Stocks, Dies, and Taps, 18in. Ratchet Braces, Selbeyes' make. Exchange for Bicycle or Tricycle.—W. J. Powell, 13, Blaina-road, Abertillery, Newport, Mon.

Wanted, 52in. or 54in. **Bicycle**, in exchange for very valuable Electrical Apparatus. Send particulars in return for list.—Geo. Pendrill, 9, Salisbury-street, Bolton-road, Bradford, Yorks.

Exchange, **Lathe and Fretsaw** (Britannia Co.) cost £5 5s., for Books, Saw Bench, or offers.—J. Thomson, Tynet, Fochabers.

"**English Mechanic,**" from October, 1878, to present date, complete, in good condition. Offers.—Geo. Smith, 8, Hawthorn-street South, Sunderland.

"**Cassell's Popular Educator,**" in 16 2s. parts, new. Will exchange for good Parallel Vice.—C. B., 16, Broadway, London Fields.

Wanted, small **Dynamo and Lamp**. Exchange for Vertical Double-action Steam Engine, 2½in. stroke, 1in. bore.—Wilson, Rock House, Clapham Common, London.

"Wanted. "**Ally Sloper's Half Holiday,**" from the commencement to the end of September, 1884. Good exchange.—L. Wilson, Rock House, Clapham Common, London.

**Bench Drilling Machine**, foot power, suitable for model work, with drills; offers wanted.—17, Peach-street, Queen's Park Estate, Harrow-road, A.C.

48in. **Bicycle**, roller bearings, new rubber tyres, lamp, bell, and tools, in good condition; also useful grindstone in frame.—Address as above.

Wanted, 36in. or 40in. **Bicycle**, in exchange for good Silver Hunter Watch, or Griscom Pattern Motor.—H. Howell, 61, High-street, Peckham, London.

Bichromate **Battery** of eight cells, 2-quart size, very powerful; will exchange the whole or single cells; what offers?—W. Goodyear, New-road, Spalding.

**Electric Motor**, by Cuttriss, equal to new, cost £1 10s. Will exchange for good Watch, or anything useful.—W. Goodyear, New-road, Spalding.

Series **Dynamo**, Paccinotti armature, 5½ by 3½, lights six 10 c.p. lamps; exchange to value of £4; electrical or mechanical offers preferred.—J. Fulwell, 54, Craven-street, Coventry.

**Youths' Tricycles**, part finished, 3 unsold, Perambulator Wheels, Axles, complete; Circular Saw and Polishing Machine, foot-power; exchange.—Smith, Bilston-road, Wolverhampton. Stamp reply.

First-class new **Bicycle**, ball bearings. Exchange 6ft. screw-cutting gap lathe.—E. Simpson, Bridge-street, Mansfield, Notts.

"**Spreston's Practical Casting and Founding**," new, cost 18s. Exchange "Rose's Practical Machinist," thirteenth edition, or offers.—E. Simpson, Mansfield.

Wanted, small **Dynamo**, by good maker, about 40 candle-power, Gerard's make preferred, in exchange for small Rifle (Tranter's patent), value £4; no rubbish.—Particulars, T. A. C., Fairfield House, Warrington.

5½in. **Telescope O.G.**, in cell, 9in. mirror, wants resilvering; 10in. Gregorian speculum.—5, Stanley-road, Ball's Pond, N.

**Iron Drums**, two 8 gallons and two ten gallons, clean, suitable for spirit or varnish, cost 4s. 6d. and 7s. 6d.—Fleming, 220, High Holborn.

**Amateur Printer's Frame** and twelve cases, quite new, exchange, or 30s.—Fleming, 220, High Holborn, W.C.

## THE SIXPENNY SALE COLUMN.

*Advertisements are inserted in this column at the rate of 6d. for the first 16 words, and 6d. for every succeeding 8 words.*

**Motor Castings**, materials for Electric Bells, Batteries, Galvanometers, Intensity Coils, Microphones.—King Mendham, and Co., Bristol.

**Insulated Wire Table**, showing size, weight, resistance per foot, feet per ohm, &c., price 3d.—King, Mendham, and Co., Bristol.

**Standard Ohm**, in box, copper poles, guaranteed correct to ten thousandth of ohm, 21s.—King, Mendham, and Co., Bristol.

**Wimshurst Influence Machine.**—Sole Manufacturers of Improved Pattern. Numerous testimonials as to thorough efficiency.—King, Mendham, and Co., Bristol.

**Galvanometer Cards**, improved for tangent and ordinary combined, 2½in., 8d.; 4in., 10d.; 6in., 1s.; post free —As above.

Write for **King, Mendham, and Co.'s** large new and reduced Price List, post free 4 stamps.

**Trouser Lengths**, 5s. each. Cheap Cloth for Ladies' Dresses, Mantles, Boys' Suits.—Hewitt, 37, Winfield Mount, Leeds. Patterns free.

**Electric Depot**, 10, Deansgate, Manchester.—Electric Breast Pins, 25s. Electric Bells, 4s. Induction Coils, 8s.—Millar, Proprietor.

**Chemical Apparatus.** — Catalogue, 90pp., 500 illustrations, posted 3d.—W. Hume, Lothian-street, Edinburgh.

**Photographic Apparatus and Chemicals** for professionals and amateurs. See new illustrated catalogue, post free.—Hume, Lothian-street, Edinburgh.

**Mica**, otherwise Talc.—RICHARD BAKER & CO., 9, Mincing-lane, London.

New Illustrated Price List of **Screws, Bolts, and Nuts** for Model Work, drawn to actual size, sent on receipt of stamp.—Morris Cohen, 132, Kirkgate, Leeds.

**Oxygen Gas**, compressed in cylinders, handiest and safest for limelight.—Clarkson, Compressed Gas Chemist, Bartlett's-buildings, E.C.

**Oxygen Gas**, compressed into iron bottles, liquid nitrous oxide and carbonic acid.—Clarkson, Compressed Gas Chemist.

**Oxygen Gas**, compressed into iron bottles: prices on application.—Clarkson, 28, Bartlett's-buildings, Holborn, E.C.

Astronomical **Telescopes** of all kinds and Apparatus or Fittings made by A. Clarkson, 28, Bartlett's-buildings.

**Eyepieces.**—Huyghenian of any power to fit any telescope, 15s. each. Sun Diagonals, £1. Star Diagonals, 30s.

Astronomical **Telescopes**, second-hand, by best makers.—Clarkson, 28, Bartlett's-buildings, Holborn, E.C.

"**Warne's Sheet Metal Worker**" to be sold, cheap, covers soiled.—94, St. Augustine's-road, Camden-square.

**Piles.**—Worst cases cured first application. Indian Ointment, sent 13 stamps.—Thomas Palmer, St. Helen's, Auckland, Durham.

**Harness Oil**, or for Caps of Wheels, 3s. 6d. per gallon.—Pinnel Brothers, 214, Whitechapel-road, London.

**Bamboo Fishing Rods**, 10 or 6-joint, 1s., 15 feet; 5-joint, 9½d., carriage 3d —Bristow and Co., Hull.

**Tic.**—This excruciating agony completely cured by Thomas Palmer's new remedy, and health and strength restored, 13 stamps.—St. Helen's, Auckland, Durham.

**Do we get Heat from the Sun?** No! Every one interested in science should read this little work. By R. Humphreys. Post free, 1½ stamps.—11, Cambria-street, Fulham, S.W.

**Oils.**—Lard and Olive Oils (substitute for). Reliable information. Stamp for reply.—J. M., 6, Hamlet-street, Bootle, Liverpool.

**Old Scientific Instruments**, Broken Model Engines, &c. For estimate of cost for repairing, relacquering, &c., send particulars to H. F. Lovegrove, Optical Works, Slough, who makes this class of work a speciality.

**Vermilion**, best, 2s. 4d. lb.—PINNELL BROTHERS, 214, Whitechapel-road, London, E.

**Gas Engine Oil** (best), 2s. 6d. gallon.—PINNELL Brothers, 214, Whitechapel-road.

**Lathes. Lathes.** Cheap and good. Satisfaction guaranteed. List two stamps. Best make.—Robinson, Catherine-street, Sheffield.

**Gas Engine**, two-man, cost £35; lowest price, £16. In good working order.—Box 27, Northallerton.

**Fretwork.**—Catalogue of every requisite, with 600 illustrations, free for 6 stamps.—Harger Bros., Settle, Yorks.

**Marvels.**—Double Opera and Field Glasses, from 5s. 6d. Lists, with engravings, free—J. B. Dancer's Depot, 53, Hamstead-road, Handsworth, Birmingham.

Tudsbury and Sons' Improved "High-tension" **Wimshurst Machine**, with their new Compound Ebonite Plates.—Edwinstowe, Newark.

Model **Steamboats**, post free 9d., 1s., 1s. 3d., 1s. 8d. 1s. 11d. Not approved money returned.—See below.

**Batteries.**—Bunsen's, Daniell's, Bichromate, 1s. each, in box, post free, 1s. 6d.—G. Hailey, Novelty Stores, Seaforth, Liverpool.

**Sol-fa Dance Music** for any instrument, post free, 7d.—Brown, Music-seller, 1, Grahame-street, Leith.

**Planing**, not exceeding 10in. by 10in. by 8in.—B. W. Clegg, 18, Belinda-street, Hunslet, Leeds.

For **Model Work** (wheel-cutting in brass only); also Boring, Turning, and Screw-Cutting.—Clegg, as above.

**Violin** for sale, magnificent solo tone, perfect preservation, labelled "Antonius Stradvarus, 1690," with case and bow, suit lady or gentleman; 25s.; cash needed; approval with pleasure.—Mrs. Stokes, 50, Myddelton-street, Clerkenwell.

**Planing Machine**, 36in. by 12in. by 12in. Patterns and over 2 cwt. castings, 55s.—N., 15, Dudley-terrace, Grantham.

5in. centre, 4ft. bed, iron **Lathe**, by Munro, division plate, slide rest, oval and eccentric chuck combined, several cup chucks, catch plate, numerous tools, drills, &c., good as new; cost £60; price £35.—Seen by appointment, Balck, 41, Poland-street, W.

**Fishing Bait.**—"Red Ching."—This celebrated Chinese bait received first prize in Fisheries Exhibition. Will keep for years. Salt and fresh water fish attracted from a long distance in large numbers by its peculiar odour and colour, take the bait voraciously. One packet will take bushels of fish.—Post paid, 1s. 2d.—Agent, Dr. Evans, Importer, Shirley, Southampton.

**Gas Engine** for sale.—One of Barker's Patent Universal ½ h.p. horizontal Gas Engines, with all their latest improvements, including water tank, gas bags, all pipes and fittings, as good as new, been very little used, price £30.—J. K., 1, Arthur-street West.

**Household Dyes**, 20 colours, cheap, cleanly, and expeditious. Sold by the manufacturer in 1d. and 6d. packets; gross, 7s. and 42s. Sample 2 or 7 stamps.—T. E. Hoyle, Blackley, Manchester.

**Chlorodyne**, Hop Bitters, Fruit Salt, Blue-black, Jet Black, Waterproof Inks, Recipe, 7d. Three 13d.—Stanley, 119, Manchester-road, Poplar.

For sale, powerful **Slide-Valve Engine**, vertical cylinder, 1½ bore by 3in —E. B., 16, Broadway, London Fields.

**Mirror Galvanometer**, 1,900w., 35s. Polarised Relay, 250w., 15s. Rheostat, 21w., 10s. 6d. All new. Photo. 6d. —Vincent, 57, Princess-terrace, Regent's Park, London. Letters only.

**Incandescent Lamps**, 20 candle-power, To clear stock we are offering at 2s. 6d. each, less discount.—Kinetic Engineering Co., 69, Saint Martin's-lane, W.C.

3½in. **Astronomical Telescope**, finder, 3 eyepieces, mahogany garden stand, £14.—44, Hazlewood-road, James street, Walthamstow.

**Force Pumps** for testing model boilers, all brass, 5s., Castings, 3s.—Leech, South View, Hayfield, Stockport.

**Bicycle**, 48in. Coventry Machinists' Co., very little used, price £4.—As below.

Cunningham's Patent **Ornamental Wood and Metal Cutting Machine** and Drilling Apparatus, combining fret and circular saws and ornamental drills, £6.—As below.

**Metal Planing Machine**, to plane a surface 12in. by 11in. by 11in., hand or power, £10 10s.—As below.

**Change Wheels** for 6in. Lathe, full set, quite new, the property of amateur.—Inquiries, stamped envelope, L. Stansell, 16, Hardy-street, Maidstone.

"**English Mechanic**," 1881, four numbers missing, unbound, good condition, 2s.; also "Photographic News," 1682, complete, 4s. 6d.—Barnett, 1, Newhall-street, Dudley.

**To Chemists and Aerated Water Manufacturers.**—Pure expressed Lemon Juice, three shillings per gallon. —J. Meadows, Distiller and Cordial Manufacturer, 44, Humberstone-gate, Leicester.

"**English Mechanic**," Vols. XXII. to XL., unbound, 40s.; cost 80s.—W. Mayor, 63, St. Stephen-street, Salford.

£1 4s. buys 480 numbers "**English Mechanic.**"—Apply, G. Sparkes, 22, Sultan road, Landport, Portsmouth.

**Lathe Tool Holders**, 3s. Tools, 4d. each. Much cheaper and handier than forged tools.—S. Beeching, Mareham-le-Fen, Boston.

**Gas Engines**, 1, 2, and 4-man, simple, good, and cheap. Numerous references. Guaranteed.—Ellis Butterworth, Rochdale.

**A Treatise** on the Manufacture and Medical Value of Koumiss, 12 stamps.—R. Lawrence, 53, Aitkenhead-road, Glasgow.

"**Knowledge**," Nos. 1 to 170, with star maps, two volumes bound.—Hanson, Coatham, Redcar.

**Dynamo**, 30 c.-p., shunt, jack-in-box, speed flywheel, six 5 c.p. lamps, on base, warranted to fully light the six lamps; price, all complete, £4 10s. Come and see it work.—H. Jones.

**Dynamo**, Jones's patent H, warranted to give at 1,500 35 volts, 8 ampères; no dead points; splendid motor; price £5.—H. Jones.

**Formulas Worked Out** for winding Dynamos from 10 c.-p. to 500 c.-p., 8 stamps each.—H. Jones.

**Dynamo Castings**, Jones's patent H: 8 c.-p., 5s.; 16, 5s. 6d.; 20, 6s. 6d.; 30, 7s.; 70, 16s. a set.—H. Jones.

**Dynamos**, finished: 8 c.-p., 30s.; 16, 36s.; 20, 40s. 30, 50s.; 70, 100s. each.—H. Jones.

**Dynamos** for house lighting.—Jones's Patent Laminated Fields and Armatures, 5, 6, and 7 lights, £6, £7, and £8 each.—H. Jones.

**Dynamo Machines Repaired.** Motors, with wire, 5s. 6d.—H. Jones, 48, High-street, Lambeth, S.E.

**New Time.**—Alter your Clocks and Watches. Twelve Sets of figures, with instructions, 6d.—Wheeler, Preston.

**Water Motors**, for sewing machines, organettes, window advertisements, 32s., 42s. List one stamp.—Wheeler.

**Fan Castings.**—Improved Registered Designs; sets 4in., 3s.; 6in., 4s.; 8in., 5s. Drawings, 4d.—Wheeler, Engineer.

**Water Motors.**—Complete one horse-power, £9. Half, £6; Quarter, £4; Eighth, £3.—Thomas Wheeler, Preston.

**Coca Leaves.**—The best, safest, and cheapest stimulant. Consignment of choice quality just received.—Marks and Co.

**Coca.**—Sample packet, with medical and scientific opinions. 13 stamps.—Marks and Co., 17, Newcastle-street, Farringdon-street, E.C.

Steel **Name Stamps**, 3d. per letter. Figures (set), 2s. 4d. Letters, 6s. 4d., per post.—E. F. Baldwin, Robinswood-hill, Gloucester.

**Model Steam Engines**, made or repaired, separate parts fitted up, boilers made to order; sets of castings of every description.—Lucas and Davies, 21, Charles-street, Hatton Garden, London.

**Printing.**—100 Bill Heads, 1s. 3d.; 100 Business Cards, 1s. 3d. Larger quantities great reduction.—Brooks and Co., Rotherham.

**Electric Indicators**, Bell, &c., royal letters patent. —Halbart Works, 27, Penton-place, Pentonville-hill. Price list trade.

Electric, Pendulum, or **Drop Movements**, 24s. per doz. Handsome Circular 3in. Bell, 4½ mahogany French polished base, 5s.—Above.

**Lathe**, &c., for sale, £3. Can be seen any evening.—Hills, 65, Monnow-road, Bermondsey.

**Amateur's Depot** for Electrical, Mechanical Scientific, and other requirements. Also all Fretwork necessaries.—111, Paddington, Liverpool.

**Models Made** for Inventors, Lecturers, also of Buildings, &c., in ancient light questions, and other purposes. —Chas. A. Barnes, 111, Paddington, Liverpool.

8ft. brass **Astro. Telescope**, 5¼ o.-g., no stand, £8.— S., 211, Ball's Pond-road, N.

A good ⅛th **Objective**, by Swift and Son, angle 150, with adjustment; cost £5; price £3.—Samuel Topping, Bellvue, Southgate-road, Wood Green.

**Incandescent Carbon Lamps**, low resistance, 3s. each. Fairy Lamps, 3s. 6d. Platinum Lamps, 1s. 3d., post free. —Todd, 14, Wentworth-road, Manor Park, Essex.

**Galvanometers**, 2s. 6d. Ditto Delicate Astatic, 5s. Ditto, Tangents, with glass shade, 10s. Am-meters, 5s. Voltmeters, 5s.

**Wheatstone's Bridges**, 5s. Standard Ohms, 2s. 6d. Standard Daniell's Cells, in box, for exact measurement, 5s. each. —Bottone.

**Wimshurst's** 12in. **Glass Plates**, fitted with spindles ready for mounting, 6s. per pair.—Bottone, Carshalton.

**Dynamo**, hand, second-hand, £2; will light 5 candle Swan Lamps, &c.—S. Bottone, Stanley-road, Carshalton.

**Boiler**, vertical, 1-horse, £6. Engine, £3; in excellent order.—79, Dudley-road, West Bromwich.

**Batteries.**—To the Trade. Pint Bunsen's, Daniell's, Bichromate, 9s. dozen; other sizes in proportion.—See below.

**Electro-Motors**, 14s., 24s., and 75s. doz. List free.— J. Hanks and Son, Seaforth, Liverpool.

To be disposed of, **Watchmaker and Jeweller's Business.**—For full particulars, apply to Roberts, 31, High-street, Mold.

Last 66 parts of "**English Mechanic**," quite clean, and four parts of "Amateur Work"; lot, 6s. 6d.—As above.

Thorough good Rack English **Lever**, in first-class order, heavy cases, £2 5s. Approval deposit.—As above.

The **Victor Vacuum Engine**, cheaper in first cost and working than steam or gas engines.—Below.

**Prices** from £15 upwards. All particulars from the Victor Engineering Company, Liverpool.

**To Amateurs.**—Bankrupt Stock of Tools of all kinds at less than half usual prices.—Below.

New Vertical **Boiler**, 30 inches high, to "Invicta's" Specification; internal firebox, with all fittings, complete; cost £23. Price £12.—Victor Engineering Company, Liverpool.

**Reading the Hand.**—A Chart with full particulars, 7d.—H. Dyke, 21, North-street, Taunton.

**Microscopic Objects.**—Very fine Volvox Globator, Tube, 8d., free.—J. H. Markham, 119, Westwood-street, Peterboro'.

Hand **Sewing Machine**, "The While," quite new, cost £4; price £2.—W. Goodyear, New-road, Spalding.

**Electric Lighting.**—Fifteen Copper Oxide Cells, trough pattern, 16 by 8, in first-class condition, including zincs; also 40lb. Copper Oxide; £6; a bargain; packed.—F. Hudson, Battle, Sussex.

**Model Engine Castings**, best and cheapest. See list (stamp) and compare.—Wood, Dalley-street, Broughton, Manchester.

Lady's solid **Gold Watch**, gold dial and handsomely engraved, perfect timist, 31s. 6d. Genuine bargain.—Below.

Gent's size **Watch**, with seconds, perfect condition, first 8s. 6d. has it; bargain.—C. Marston, 73, Allhallowgate, Ripon.

**Selenites**, Red and Green, Blue and Yellow, 1s. each, post free.—G. Scoram and Co., Bradford.

**Micrometers**, divided into hundreds and thousands of an inch, 3s. 1d. post free.—Scoram and Co., Opticians.

**Camera Finder**, for keeping the object in the centre of the field, 7s. 9d., post free.—Scoram and Co., Bradford.

**Canary Medium**, perfectly safe for all dry plates, 4d. sheet, free.—Scoram and Co., Bradford.

**Pocket Coil and Battery**, in mahogany box, and cage, with full instructions, complete. Sample, 1s. 6d. carriage free.

**Electric Motor and Battery**, in glass jar, complete. Sample, 1s. 6d. Trade supplied.—A. Jones, 98, Packington-street, London, N.

7in. by 5in. **Portrait Camera and Lens**, complete, without dark slide, 15s.—G. Waller, 2, Middlegate-street, Yarmouth.

**Galvanic Machine**, dial, 2 bells, switch, 4 handles, with box complete, price £6; photo., 6d.—Jacob Tate, Bibside, Couper-lane, via Newcastle-on-Tyne.

Vertical Slide-Valve **Engine**, cylinder brass, with brass bearings, 1in. bore by 2½in. stroke; Copper Boiler, 12½in. by 4½in. piping and taps complete.—A. E. W., 17, Pembroke-street, Oldham.

One Ebony **Brace**, new, brass-plated, and 3 dozen bits, bright, cost 32s.; will take 18s.—Wilfred Baxter, Hill Foot, Sheffield.

**Tricycle**, Royal Mail, rear steerer, ball bearings to all wheels, good condition, £6 6s.—Jacob, 1, Landseer-road, Bow, E.

**Mesmerism.**—Complete written instructions. Success guaranteed. Fee, 2s. 6d.—Professor, 32, Clarendon-road, Anfield, Liverpool.

**Rubber Stamps.**—Your Name, Business, and Address in full for 1s. 6d.—F. Harrison, 5a, Southwell-street, Liverpool, S.

Over 200 Nos. "**English Mechanic**," dating from 1874 to 1884, 10s.—R. P., 91, Tabard-street, London, S.E.

"**English Mechanic**," Vols. XXVII. to XXXIII., clean, indexes, 2s. each.—L., 26, Palace-road, Upper Norwood.

**Dr. James's Compound Quinine Bitters** are the most effectual of all medicines for debility, nervousness, &c.

Send 1s. 2½in. in stamps to **J. R. James**, Cardigan, and receive by post this valuable aromatic stomachic bitters.

**Boiler.** 6 H.-P. vertical, with 2 cross tubes; 6 H.-P. Multitubular, suitable for launch, both in good working order, with mountings.—Lowe, Wallis road, Hackney Wick.

**Engine.** 2½-horse oscillating, with pump, flywheel, very strong cheap.—Lowe, Wallis-road, Hackney Wick.

**Pumps.**—One pair 6in. double action, with slings, guides, crank, &c., complete. Tangye; special, 4½in. by 2¼in. cylinders. No. 8 Double-action Vauxhall Donkey, bargains.—Lowe, Wallis-road, Hackney Wick.

**Rubber Belt,** 3 ply, 125 feet by 18¾ inches wide, cheap.—Lowe, Wallis-road, Hackney Wick.

**Pulveriser,** Lucop's B size, and Crushing Machine, Mote's; both quite new.—Lowe, Wallis-road, Hackney Wick.

**Forges,** portable, quite new, circular and square, from 50s. each; bargains.—Lowe, Wallis-road, Hackney Wick.

**To the Readers of the "English Mechanic."**—Mr. William Bundy begs to inform his fellow-readers that, after noting all the principal improvements in the machine-tool line for the past ten years, he has recently concluded to commence the manufacture and sale of improved tools and machinery under the style of William Bundy and Company. He has already finished several lathes, planing and drilling machines, which he is willing to sell at extremely low prices. The quality of the goods is simply the best, as all possible improvements are included, and no skill or labour has been spared in the finish and material. Full particulars and drawings direct from photograph, and a guaranteed representation of the article quoted for will be gladly sent on application. Every tool sent out will be despatched on the condition that it is subject to returnal if unsatisfactory. The chief features of improvements in lathes are the headstocks, the treadle, the slide-rest, and the change-wheels. Great attention is paid to Lathe Parts, Accessories, &c., such as Chucks, Rests, Headstocks, Beds, &c., and also other machine parts. Special Machinery made to order at a minimum charge. Orders for Joiners', Carpenters', Smiths', and other tools, as well as hardware, brassfoundry, &c., &c., will receive special attention. In conclusion, prices will be as low, or lower, than the cheapest, whilst strict attention and personal supervision will mark all transactions. Correspondence invited.—London office, where samples may be seen, 62, Holborn Viaduct, London.

**Lathe,** 5in. centre, 5ft. bed, screw-cutting, treadle, new, cheap.—W. Bundy, 62, Holborn Viaduct, London.

**Dark Slides,** double mahogany or walnut, best make, ¼-plates, 4s.; ½-plate, 7s. 6d.; whole-plates, 12s. 6d.

**Printing Frames,** polished pine, best make. ¼, 7s. 6d. per dozen; ½, 12s. per dozen; 1-1, 18s. per dozen.

Carte **Camera,** Lens, walnut Dark Slide, with chemicals, dry plates, printing materials, printing frame, &c., complete, 21s.

Tourist **Printing Frames,** ¼-plate, polished pine, 3s per dozen.—F. Moore, 1, Naas-road, Wood-green.

**Locomotive Photographs,** G. N. Ry., 664; Midland, 1539; G. E. Ry., compound; specimen carte and list, 5 stamps.—F. Moore, 1, Naas-road, Wood-green, N.

**Pulley Blocks,** pair 4in. double and treble, brass sheaves, price 15s.—Ames, 79, Grange Walk, Bermondsey.

**Universal Trade** and Amateur Supply.—Lecture requisites; light, heat, air, water, geology, engineering, chemistry, photography, &c. Wholesale and export.—Caplatzi.

Frictional and **Induction Machines,** Plates, Cylinders, Stands, Conductors, Glass and Vulcanite, hundreds of Lecture Accessories.

**Coils.**—Experimental, Resistance, Medical, Dynamo, Bell, Telegraph, Galvanometer, and for every other purpose; matchless cheapness.

**Batteries.**—Thousands of most approved forms for lighting and experimenting, and medical. Our own, the most convenient, durable, and economical.

**Telegraphs,** Bells, Indicators, Phonographs, Dynamos, Motors, Arc and Incandescent Lamps, Leads, Switches, Keys, and hundred accessories.

**Optics.**—Noted house for cheap Telescopes, Microscopes, Polariscopes, Spectroscopes, Graphoscopes, Camera Lucida, Obscura, Polyramas, and their parts.

**Lenses,** Prisms, Specula, Object-Glasses, Eyepieces, Finders, Cells, Tubing, Racks, Hooks, Joints, Optical Glass, Tools, &c.

**Photography.**—Immense quantity of new and old apparatus, very cheap. Pocket Microphoto sets, 60s. Lancaster's three-quarter price. Camera, with 9 lenses.

**Lenses.**—Ross, Dallmeyer, fine foreign, good Stands, Printing Materials, Gas Rolling Presses, Focussing Glasses, Negatives, exceptionally cheap.

**Machinery.**—Good Lathes, Litho, Printing, Stamping Presses, Flatting Mills, Wheel-cutting Engines, Swiss Mandrels, Wire Covering Machines.

**Micrometer,** Diffraction, Grating, Engravers' Ruling Machine, Seal Engravers' and Lapidary's Lathes, various Slide Rests, Centring Chucks, &c.

**Clock and Watchmaker's Tools,** Clock Movements, Dials, Glasses, small and large Clockwheels, Springs, Screws, Parts, Fittings, for Models of all kinds.

**Model Engines** to 2 H.-P. Immense number of 1, 2, 3in. stroke ones; good Boilers, Cylinders, Gauges, Wheels, Cocks, Pumps, Boats.

**Chemistry.**—Fittings-up of complete Laboratories, Copper Troughs, Gasholders, Stills, Baths, Porcelain. Many Balances, 1-2 thirds price.

Catalogues, 2d. **Caplatzi,** Science Depot, Hire and Exchange, Chenies-street, Tottenham-court-road, near British Museum.

**Battery,** Bichromate, new, double salt. No crystallisation in cells. 56lb. lots, 6½d. per lb.—R. A. Lee.

**Bichromate,** perfectly soluble in cold water, 10 per cent. higher electrical efficiency than potash. 7lb. sample, 7d. lb.

**Patent Electro-Motors,** Patent Primary Batteries, Patent Lamp Holders.—Lee's Stand, 1358, East Arcade, Inventions Exhibition.

Chaster's **Electro-Motor Castings,** 3s. 6d. set. As described in "E.M.," 1026, 1027, 1029, and 1041.—R. A. Lee.

Patent Primary **Battery** for above, or 5 incandescent lamps £3 10s.—R. A. Lee, 76, High Holborn, London, W.C.

**Patents, Designs, Trade Marks.** Notice.—James Stevenson, The People's Patent Agent, 20, High Holborn, London, W.C.

**Incandescent Lamps** (carbon), 2 to 8 candle-power, 2s. 6d. Trade supplied. Swan's 20 c.p., 4s. 6d.—Patrick.

**Arc Lamps,** several second-hand, £2 each. Powerful Motor or Dynamo, £3; ditto, superior, £4 10s. Clearing out.

**Air Pump,** double-barrel, rack, massive brass fittings, on Spanish mahogany; cost £8; price £3 10s.—Patrick.

⅜th spark **Coil,** 8s. Cylinder Electric Machine, 5s. Engine Castings, half-horse, 10s., partly finished.—Below.

**Cornet and Box,** 10s. Dark Room and Feet, 5s.—H. Howell, 61, High-street, Peckham, London.

"**English Mechanic.**"—Any back numbers 3d. each, free; Volumes, 8s., free.—Sladen, 33, Cank-street, Leicester.

"**English Mechanic,**" Vols. I. to XXX., 12 vols. bound. 1s. 6d. each volume, including binding, good condition; any offer.—M. N., 79, Mare-street, Bethnal-green.

**Illustrated List** of Electrical Apparatus, 2 stamps.—Patrick and Sons, 529, King's-road, Chelsea, S.W.

The Amateur's and Dentist's **Gas Engine.** Simple and compact; complete Castings, 42s. Drawing, 5s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

Half horse-power Horizontal or Vertical **Engine** Castings, ports in cylinder, 12s. 6d. Drawing, 18 stamps.—A. Dorrington, West Gorton, Manchester.

Launch **Engine Castings,** 3in. cylinder, 26s.; 4in., 50s.; 5in., 70s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

Bench **Drilling Machine.** Castings, 3s. 9d. Forgings, 3s. Drawing, 8 stamps.—A. Dorrington, West Gorton, Manchester.

No. 2 **Drilling Machine,** self-acting feed motion. Castings, 7s. 6d. Forgings, 5s. Drawings, 18 stamps.—A. Dorrington, West Gorton, Manchester.

4½in. **Fan Castings,** 3s. per set. Drawing, 4 stamps.—A. Dorrington, West Gorton, Manchester.

4-jaw **Chuck Castings,** plate 6in. diam., 3s. per set.—A. Dorrington, West Gorton, Manchester.

Horizontal **Engine,** cylinder 1¼in. by 2in. Castings, 6s. Working Drawing, 12 stamps.—A. Dorrington, West Gorton, Manchester.

Model Compound Condensing Marine **Screw Engine,** perfect model. Castings, 10s. Drawing, 2s. 6d. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

3in. back-geared **Lathe.** Castings, 14s. 6d. Working Drawing, 18 stamps.—A. Dorrington, West Gorton, Manchester.

**Test Pump** for testing Model Boilers. Castings, 2s. 6d. Drawing, 6 stamps.—A. Dorrington, West Gorton, Manchester.

**Rotary Pump,** most useful for garden and lawn purposes. Castings, 10s. Working Drawing, 24 stamps.—A. Dorrington, West Gorton, Manchester.

**Dorrington's Castings** are supplied at the lowest possible prices consistent with good material; price list, 1 stamp.—A. Dorrington, West Gorton, Manchester.

## Situations.

Scientific Instrument Maker seeks Situation as Assistant to scientific gentleman, in laboratory, or in any place of trust; at present engaged in optical trade.—Address, 99, Northcote-road, Wandsworth Common, S.W.

Cabinetmaker Wanted, used to small work, and who can use the lathe; one accustomed to electrical work preferred.—Apply, first by letter, stating wages, &c., to Walsall Electrical Co., Walsall.

## Addresses.

Potato Cleaners.—I have been a maker of this article for some years.—S. Ibbotson, 98, Whitefield-street, W.

I want the address of Mr. Charles Groombridge, who wrote the Letter No. 24,466, on page 414, on Aërial Navigation.—Albert Hammond, Bondgate-green, Ripon.

Wanted, to communicate (letters only) *re* Manufacture of two valuable Articles of Food.—Cypher, care of Mr. Meaby, Orchard-street, Katesgrove-lane, Reading.

## Wanted.

Agents Wanted.—Morgan's celebrated Improved Scale Preventing Compound. Nothing better or cheaper.—W. H. Morgan, Engineer, Gloucester.

Old Microscopes.—Send rough sketch, with dimensions, state, and price, to J. Mayall, Junior, 224, Regent-street, London, W.

Wanted, Drilling Tool, by Bolez, for Watch work.—Address, James Beck, Old Court Hall, Godmanchester, Hunts.

Negatives (good amateur), picturesque scenery, &c., ¼ and ½-plate.—Description and price to Ryder, Matlock Bath.

Back-geared Lathe Heads and Slide-rest wanted.—Particulars and price, Jas. Hudson, Westmorland-lane, Newcastle-on-Tyne.

---

**£20 TOBACCONISTS COMMENCING.**—An Illustrated Guide (110 Pages), HOW TO COMMENCE BUSINESS RESPECTABLY, 3 stamps.—H. MYERS and CO., Cigar and Tobacco Merchants, 109, Euston-road, London. Wholesale and Export Only Telephone No. 7541.

**G. BIRCH AND CO., BLOOM STREET TOOL WORKS, SALFORD, MANCHESTER.** Manufacturers of High-class Amateur Tools, Self-acting Slide and Screw-cutting Lathes, Drilling, Shaping, Milling, and Planing Machines. SPECIAL Amateur Milling Machine on independent stand, with treadle motion, complete. MEDALLION TURNING LATHES of New and Improved Design. Chucks and Ornamental Turning Apparatus of every description. WHEEL CUTTING, Circular and Straight Line Dividing and Drilling. ENGRAVERS' RULING and ROUTING MACHINES, &c. Amateurs supplied with Materials; Castings in Cast or Malleable Iron, Phosphor Bronze, Gunmetal, and Steel. Hard Woods kept in stock.
*Sole Authorised Makers of Amateurs' Tools Invented by Mr. Jesse Lowe.*

**DO YOUR OWN PRINTING!—The "OPTIMUS" PRINTING PRESS** prints equal to any trade machine. Anyone can use it. Press, Type, and Accessories, 20s. Testimonials and specimens of work, one stamp.—A. HERBERT, 124, Bridport-place, Hoxton, London, N.

**HARMONIUM and AMERICAN ORGAN FITTINGS** of every description; also Wood and Metal Pipes, Small Work, &c. Esteve's and Turban's celebrated reeds voiced and unvoiced; keys, pans, &c., &c. Trade supplied with Harmoniums and Organs. List, stamp.—W. HANDS and CO., Organ Builders, Bedford.

**TO SHOEING and JOBBING SMITHS.**—WANTED, for a Gentleman's Estate, a first-rate SHOEING SMITH, competent for horses of all kinds, and to execute general repairs.—Apply, stating age, married or single, wages expected, with references, to Mr. JOHN TUDOR, Marlow, Bucks.

READY SHORTLY,
HANDSOMELY BOUND IN CLOTH,
VOL XLVIII.

# HISTORICAL NOTES ON THE CASSEGRAIN.—II.

By DR. ROYSTON PIGOTT, F.R.S., M.A.

### The Great Southern Cassegrain.

THE following resolution of the Council of the British Association displays the earliest efforts towards the construction of this great instrument:

"That it is expedient to proceed without delay with the establishment, in the Southern Hemisphere, of a telescope not inferior in power to a 3ft. reflector; and the President of the British Association, with the assistance of the following gentlemen, viz.: The Earl of Rosse, Dr. Robinson, Lord Wrottesley, J. C. Adams, Esq., the Astronomer Royal, J. Nasmyth, Esq., W. Lassell, Esq., Sir D. Brewster, and E. J. Cooper, Esq. be requested to take such steps as they shall deem most desirable to carry out the preceding resolution." (This was read at the Council of the Royal Society, Nov. 22, 1852.) The name of John Phillips was subsequently added, as also Sir John Herschel, Sir John Lubbock, and the Dean of Ely.

Under these circumstances arose a voluminous and, as it were, an all-round correspondence. Mr. Grubb, of Dublin, was intrusted with the execution of a Cassegrain telescope of 32ft. focal length and 4ft. diameter of mirror. It arrived safely about Jan., 1869. Mr. Robert Ellery acknowledged the safe receipt of all the apparatus, and incidentally remarks: "The *specula* are still in thin coats of varnish, and their surfaces appear in good order." It appears the varnish was made of *shell-lac.* The letter was dated Jan. 4, 1869. On Aug. 13, 1869, he further states:

"I am not satisfied with the performance of this great instrument, and I do not think the mirrors are at all perfect in figure; I have not yet seen anything like good definition of a planet with the lowest power (220). Of course, we get plenty of light, even with the nebulæ, but no definition with bright objects."

To this damnatory opinion the Astronomer Royal for Ireland, who had designed and calculated all the details, laboriously replies to a member of the Council:

"Like you, I am much surprised . . . It is fortunate Mr. Grubb put it in his contract that the telescope should be tried by the committee before he sent it from Dublin . . . It fully divided $\gamma^2$ Andromedæ.

"Mr. Grubb's command of figure is so great, that I am certain there may be other causes for this than any fault of the maker, or of the committee who passed it."

Mr. Le Seur, who was in charge of the telescope "out," says that the specula, by the advice of Mr. Lassell, were coated over with shellac varnish.

The large speculum was originally attached to the tube in its varnished condition; on the first favourable occasion it was taken down and *unvarnished*—a process which proved more troublesome than had been anticipated. The lac was very refractory, and the difficulty of removal exaggerated by the extreme heat then prevalent. After a process of solution in alcohol, "mopping up" (*sic*) and washing with water frequently repeated, a large number of markings caused originally by the varnish brush were apparent, and the whole surface had a mealy appearance (!)[*]

In spite of all these *contretemps*, it is written by a principal observer, "I never once obtained with it what I should call *moderately good definition.* I tried it on Saturn many times, but could not get any detail whatever. The larger division on the ring was visible, but was never distinct. The mirror at first had a mealy yellow appearance after the lac had been removed, which was thought to be due to a little residual varnish.

Why, then, did this great telescope at first fail in Australia, to realise the sanguine expectations of the committee? The maker, and the committee's deputation to Dublin, were both satisfied. Hear Mr. Howard Grubb: "I cannot understand Mr. Le Seur that the method employed . . . could not be supposed to have any deleterious effects on the polish, after stating that it was impracticable to remove entirely the shellac coating, the surface being sticky in parts, and afterwards the speculum tarnished quickly. The process was radically bad, and the speculum was left in an unclean state. . . . After months of use at Dublin, the speculum exhibited no tarnish. . . There is abundant evidence to show that speculum (A) has become unfitted for present use, solely from injudicious treatment at Melbourne." Then the committee selected to proceed to Dublin, after due inspection of Mr. Howard Grubb's work, declared it to be a masterpiece of engineering, and they were strongly impressed by the great convenience to the observer of the arrangements of the hour and polar distance circles. Now for the optical power: The telescope was tested with powers of 220, 350, and 450 (all negatives. The committee (assembled at Dublin) found that the light even of large stars was collected into small, hard, and perfectly circular discs free from rays, and though some diffused light[*] surrounded them, it was exactly concentric with the central discs. The 5th and 6th stars of the Trapezium of Orion were not only plainly seen, but were very bright; $\zeta$ Orionis was well shown, and the companion of $\gamma$ Andromedæ was clearly divided with the powers of 350 and 450, and the different tints of the components were evident. Uranus was well seen, but was surrounded with such a multitude of very minute stars that without access to the tables of his satellites it was impossible to know whether any of them were seen.[†]

(*To be continued.*)

# THE INTERNATIONAL INVENTIONS EXHIBITION.—XIII.

### Photography.

THERE is probably no group in the whole International Exhibition which shows so much progress in the last twenty-five years as that devoted to photography—always excepting electricity, which for special reasons has latterly shown extraordinary development. In photography the improvements and advances of the last quarter of a century have been great and varied; but they represent the steady growth of an art which has persistently progressed since its discovery, rather than the leaps and bounds which electricity has recently made. Twenty-five years ago the wet-plate process was the only one known to those outside the circle of inventors and researchers; nowadays dry plates are everything, especially to the amateur, and processes have multiplied almost with the years since Dr. Maddox, in 1871, published an account of his method of suspending or emulsifying silver bromide in gelatine, and applying the preparation to the glass plate instead of collodion. That process, strange to say, remained for about two years in a dormant state, when, in 1873, Mr. Burgess sold gelatine emulsion, and in the following year Mr. Kennett published his method of obtaining the same result, and issued dry plates. Four years after that Mr. C. Bennett discovered that by keeping the gelatine containing the silver salts liquefied at a low temperature for several days an extraordinary sensitiveness to light was produced, and, as he gave the discovery to the world, progress in dry-plate work has been remarkable. We are not, however, just now interested in a history of the modern progress of photography; but the student will not fail to linger at the case containing the exhibits of the Photographic Society of Great Britain, for there are to be seen old pictures, the results produced by the earlier processes, old apparatus, and other objects which illustrate the progress made in the art. Amongst these is the view of Kew, taken by Nicéphore Nièpce in 1827, and the original letter sent by him to the Royal Society in the same year. Here, also, are Talbotypes of 1844, instantaneous views obtained from 1856-1865 by V. Blanchard with wet collodion; carbon prints twenty years old by J. W. Swan; Dr. Maddox's gelatino-bromide negatives of 1871, and Col. Stuart Wortley's early productions with uranium plates. The case also contains some of the earlier productions and apparatus of Woodbury, one of the pioneers of the printing processes which have played so important a part in the illustration of modern books. The collection of photographs exhibited at the different stands, whether shown to illustrate the merits of a process or the advantages of using this or that piece of apparatus or special preparation, will be inspected with pleasure by both the amateur and the professional, for, as we need scarcely say, they are almost all first rate, and a jury of experts would be required to point out in what particular the products of any one process are superior to those of others. Apparatus is shown in considerable variety, but there is little that is so novel as to call for special comment, though many ingenious appliances deserve the attention of photographers, both professionals and amateurs—the latter being a large and rapidly-increasing class, some of them quite capable of holding a position in the front ranks of the exponents of photographic art. Taking the stands in their numerical order, we will point out some of the exhibits which appear to be specially worth notice, though we cannot pretend to exhaust even the comparatively small Group XXIX. Mr. Warnerke, of Champion-hill, S.E., shows the productions of sundry processes based on newly-discovered properties of gelatine emulsions, and his negatives on gelatine tissues leave little to be desired, except it is some special paper or other substance which will enable us to dispense with glass, in which direction, as will be seen from an article elsewhere, he has been making progress. Morgan and Kidd, of Richmond, Surrey, exhibit beautiful specimens of their method of working the gelatino-bromide process for enlargements, as described at some length in No. 876, p. 417. Mr. A. A. Common, of Ealing, W., exhibits a series of astronomical photographs, including the celebrated one of the great nebula in Orion, which is shown enlarged three times, and also seven times, from the original taken with his great 3ft. silver-on-glass reflector and 37 minutes' exposure. He shows also a collection of untouched negatives of various celestial objects, and a fine photo of the moon enlarged nine times. The smaller photograph of the Orion nebula is a very fine production, and is decidedly superior to that obtained by the late Prof. H. Draper. The latter, however, had to allow an exposure of over 100 minutes, and the large stars were consequently much over-exposed. Mr. Common, too, has a larger instrument, and an aperture which will make itself felt. No finer collection of astro-photographs is to be seen, though MM. Henry, of Paris, will, no doubt, soon make a considerable advance in this branch of the art. Mr. A. L. Henderson, of King William-street, E.C., exhibits fine specimens of ceramic enamels, and his machine for coating plates with emulsion. That is not shown complete, owing to want of space, but sufficient is there to give a good idea of its construction and method of working; and Mr. Henderson also exhibits his emulsion filter, washer, &c., which will enable those interested to compare his devices with other exhibits having similar objects. Mr. W. Middlemiss, of Thornton-road, Bradford, has several ingenious devices in the shape of light portable folding cameras, having long focus, reversing back, double swing back, and all requisite movements; but in this

[*] The cause of this diffused light was subsequently discovered and removed.

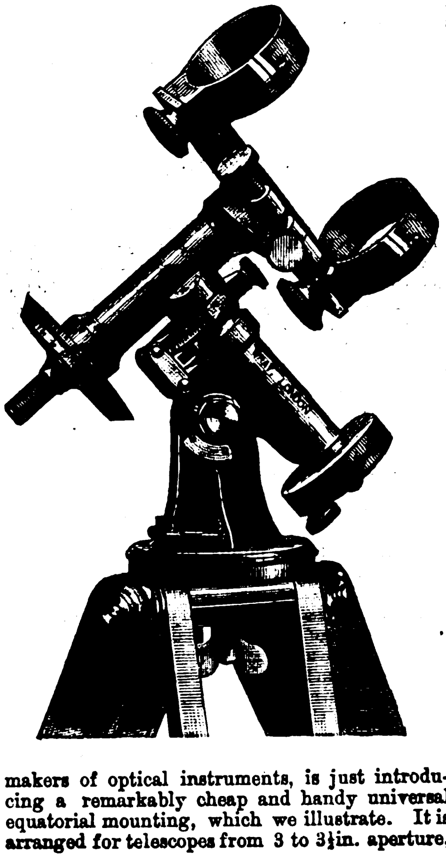
[†] On the 19th Feb., 1868, the committee assembled in Dublin had the advantage of Mr. Lassell's presence in the examination of Uranus with speculum (A). The very speculum afterwards so miserably deficient in Australia.

VOL. XLI.—NO. 1,062.

connection it may be as well to say that there is no lack of apparatus, and that it is impossible without diagrams to explain the differences between the various exhibits. It must be sufficient to state that such well-known makers as G. Hare, Calthorpe-street, W.C.; Rouch and Co., of the Strand; Swift and Son, Tottenham-court-road, W.; F. W. Hart, Kingsland-green, E, and some others, show a varied collection of cameras. Mr. Collins, Cochrane-street, N.W., amongst his photographic apparatus, exhibits a dark tent which complete weighs only 12lb. Sands and Hunter, of Cranbourn-street, W., besides cameras and shutters, exhibit a photographic gun for taking "snap shots" at moving objects (see p. 129, Vol. XL.), and a "beginner's set" of apparatus neatly arranged in a box, with a set of printing appliances similarly packed. Mr. W. Ouin, of Laurel Cottages, Tottenham, exhibits a simple drop shutter, which seems capable of withstanding much rough treatment. The model exhibited is made of mahogany, with the "drop" of ebonite, a pin with chain attachment being provided to hold the shutter up when focussing. If greater speed is required than can be obtained with the simple "drop," an elastic band can be easily fitted to pull the shutter down. Mr. Monsell, of Leeson Park, Dublin, exhibits a circular drop shutter of quadrantal shape, with a slide to regulate the amount of opening; and Messrs. Reynolds and Branson, of Leeds, show a flap shutter with a little counterpoise weight so that a slow, medium, or rapid movement can be obtained at pleasure. The London Stereoscopic Company, Cheapside, have a fine exhibit of photographs, many of them taken by amateurs, and they also display their apparatus specially adapted for amateurs. Messrs. Green and Fuidge, of Stratford-on-Avon, exhibit their patent actinometer, which is in the shape and about the size of a watch, with seven gradations of tint. The paper to be tested is placed in the instrument, and is acted upon through a perforated space in the dial. The tint produced in any observed time is thus readily compared with the seven permanent tints on the dial, and the exposure necessary for the given quality of paper and the character of the light is recorded in a note-book. The brightest light will only print the seven tints in one minute, and a light printing less than one tint in the same time is too weak for photographic work; so that the scale of seven comparison tints is capable of meeting all requirements. The actinometer is provided with a dark box, in which discs of sensitive paper can be kept ready for use. Mr. T. Furnell exhibits an adjustable instantaneous shutter attached to a camera, having the multiplex back, which we illustrated in No. 961, and is presumably, therefore, shown by Messrs. H. and E. J. Dale, of Ludgate-hill, E.C. Mr. B. J. Sayce, of Liverpool, exhibits a number of specimens made by the collodio-bromide process, in the perfecting of which he played so prominent a part. Mr. Samuels, of Hadley, Barnet, shows his improvements in cameras, by means of which double swing backs and sliding fronts are dispensed with. These consist of a taper bellows camera, with the lens-front supported by an adjustable staging of brass. There is no baseboard, and the tapered bellows enables any practical position to be obtained. Woodbury, Treadaway, and Co., of Great Saffron-hill, E.C., exhibit the Woodbury stannotype process, which we described on p. 511, No. 880. It consists in pressing a sheet of tinfoil into intimate contact with a gelatine printing surface, prepared by the well-known process, and using the tin face as the recipient of ink. Presses and plates are exhibited. Close by, the Woodbury Permanent Photographic Printing Company, of Ealing, W., exhibit the original Woodbury-type and carbon printing processes, with specimens of plates and presses; and at the adjoining stand the Platinotype Company give practical demonstrations of their process at stated hours. Some of the work exhibited is very fine, and, as our readers know, the process is simple and rapid, while the pictures produced are absolutely permanent, for they are composed of metallic platinum, a substance which, so far as is known, is perfectly unalterable. The Paget Prize Plate Company exhibit pictures produced by their gelatino-bromide plates, including those remarkable views of yachts in motion, by G. West and Son, of Gosport, which created some excitement when first shown. Mr. M. Auty, of Newcastle-on-Tyne, also exhibits two photos of lightning flashes, taken with these plates. Mr. J. W. Swan, Bromley, Kent, exhibits specimens of carbon printing, or autotype, with models and examples; illustrations of photo-mezzotint, "also known as Woodbury-type," photogravure, photo block-printing, the collodio-citro-chloride process, and gelatino-bromide process. Mr. Arnold Spiller, Canonbury, N., shows the products of sundry experiments with gelatino-chloride of silver transparencies, developed with hydroxylamine and various alkalies. At Mr. Hart's stand, mentioned above, a machine for using the magnesium light is shown, accompanied by a portrait of the late G. W. Simpson, the first taken by the magnesium light at a public meeting (1864). Marion and Co., of Soho-square, have a fine collection of apparatus, but make a specialty of their "sets for amateurs," which are sold at prices as low as 30s. for a real working apparatus. Their miniature camera in metal, about the size of one's thumb, which gives sharp little pictures 1¼in. square, is more than a curiosity, for the pictures obtained by it can be enlarged to cabinet size in a few minutes by the use of their Alpha paper. A fine specimen of Marion's blue process, so useful in the reproduction of working drawings, is sure to attract attention. Mr. Bernstein, of Finborough-road, S.W., exhibits specimens of photopeinture, a new method of reproducing oil paintings to the original or any size, which should be compared with the exhibits of what is called Anglo-French Photo-nature and Heliochromy, No. 2,725, hung on the N. wall of the East Central Gallery, in a line with the music room. No name or address is appended to this exhibit, though it is stated that they are photographs coloured without touching-up. There are many other pictures in the photographic group which deserve high praise, notably those exhibited by Mr. J. P. Mayall, Park-lane Studio, W., including the enlargements from his series of "artists at home"; but we have not space to do more than mention the fact, although we must direct attention to Mr. Foxlee's exhibit, in which he shows, by a series of examples, what he terms the "continuating" action of light in carbon prints, proving that the action is dependent upon moisture in the tissue, and is accelerated by heat.

## WRAY'S NEW UNIVERSAL EQUATORIAL MOUNTING.

MR. W. WRAY, of North-hill, Highgate, whose name is familiar to all readers as that of one of our most reliable and intelligent makers of optical instruments, is just introducing a remarkably cheap and handy universal equatorial mounting, which we illustrate. It is arranged for telescopes from 3 to 3½in. aperture, adjustable to different latitudes from 0 to 70°. The declination circle is 4½in. diameter divided on brass, with vernier reading to 2 minutes of arc, adjustable hour circle 3½in. diameter, divided on brass, with two sets of divisions and verniers reading to 30 seconds of time. Tangent screw motion in right ascension and slow motion in declination; levels and all necessary means of adjustment; brass clasps for holding telescope and strong oak tripod stand with stretcher. The equatorial mounting, packed in pine case complete, as shown, is sold for £18 10s.



## ASTRONOMICAL NOTES FOR AUGUST, 1885.

### The Sun.

| Day of Month. | Souths. | At Greenwich Mean Noon. | | |
|---|---|---|---|---|
| | | Right Ascension. | Declination North. | Sidereal Time. |
| | h. m. s. p.m. | h. m. s. | ° ′ ″ | h. m. s. |
| 1 | 0 6 2·27 ,, | 8 47 4 | 17 55 46 | 8 41 1·9 |
| 6 | 0 5 36·12 ,, | 9 6 21 | 16 36 4 | 9 0 44·71 |
| 11 | 0 4 55·65 ,, | 9 25 23 | 15 9 39 | 9 20 27·49 |
| 16 | 0 4 1·04 ,, | 9 44 11 | 13 37 11 | 9 40 10·26 |
| 21 | 0 2 53·20 ,, | 10 2 46 | 11 59 19 | 9 59 53·02 |
| 26 | 0 1 33·67 ,, | 10 21 9 | 10 16 44 | 10 19 35·79 |
| 31 | 0 0 4·56 ,, | 10 39 23 | 8 30 3 | 10 39 18·55 |

The method of finding the Sidereal Time at Local Mean Noon at any other Station will be found on p. 355 of Vol. XL.

The signs of renewed great Solar Activity, which became so notable a month or two ago, have by no means subsided, and the student should lose no opportunity of examining the Sun's disc.

### The Moon

Enters her Last Quarter at 9h. 55·3m. in the evening of August 3rd, and is New 14 minutes after Noon on the 10th. She will enter her First Quarter at 1h. 46·8m. p.m. on the 17th, and be Full at 5h. 25·2m. in the afternoon of the 25th.

| Day of Month. | Moon's Age at Noon. | Souths. |
|---|---|---|
| | Days. | h. m. |
| 1 | 20·3 | 3 42·6 a.m. |
| 6 | 25·3 | 7 59·2 ,, |
| 11 | 1·0 | 0 57·4 p.m. |
| 16 | 6·0 | 5 10·0 ,, |
| 21 | 11·0 | 9 7·6 ,, |
| 26 | 16.0 | 12 56·1 ,, |
| 31 | 21·0 | 4 4·6 a.m. |

The Moon will be in conjunction with Saturn at 2 p.m. on the 7th; and with Mars an hour later; with Jupiter at 2 a.m. on the 12th; with Mercury afterwards at 9 a.m.; and with Venus at Noon—all on the same day.

### Mercury

Is an Evening Star during the entire month, attaining his greatest elongation east of the Sun (27° 21′) at 3 a.m. on the 6th. About this time he may be seen after sunset over the W. by N. part of the horizon. His angular diameter increases from 7″ on August 1st to 10·6″ by the 31st, and by the middle of the month his crescentic figure is very apparent in the telescope.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 10 31·1 | 8 31·3 | 1 49·8 p.m. |
| 6 | 10 49·3 | 5 43·1 | 1 48·3 ,, |
| 11 | 11 2·8 | 3 18·7 | 1 42·1 ,, |
| 16 | 11 10·6 | 1 31·8 | 1 30·1 ,, |
| 21 | 11 11·2 | 0 41·0 | 1 11·1 ,, |
| 26 | 11 3·6 | 1 6·4 | 0 43·9 ,, |
| 31 | 10 49·3 | 2 55·9 | 0 10·0 ,, |

Hence it will be seen that Mercury describes a somewhat pendulum-like path in Leo, starting from a point to the south east of ρ in that con-

* Star setting. ‡ Stars have set. † A near approach.

stellation. He will be twice in conjunction with Jupiter during the month: first at 9 p.m. on the 4th, and again at 11 a.m. on the 27th. He will further be in conjunction with Venus at 5 p.m. on the 8th.

### Venus

Is an Evening Star too, and may be caught after sunset glittering above the horizon to the north of west at the beginning of August, and to the south of it towards the end of the month. In the telescope she presents the appearance of a small bright gibbous disc, increasing in diameter from 11″ on the 1st to 12·2″ by the end of the month.

| Day of Month. | Right Ascension. | Declination | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 10 23·1 | 11 41·3 N. | 1 41·8 p.m. |
| 6 | 10 46·0 | 9 21·5 ,, | 1 45·0 ,, |
| 11 | 11 8·6 | 6 55·7 ,, | 1 47·8 ,, |
| 16 | 11 30·8 | 4 25·4 ,, | 1 50·3 ,, |
| 21 | 11 52·9 | 1 52·0 ,, | 1 52·7 ,, |
| 26 | 12 14·8 | 0 43·0 S. | 1 54·9 ,, |
| 31 | 12 36·7 | 3 18·1 ,, | 1 57·0 ,, |

The path indicated by the above ephemeris commences at a point north-west of ρ Leonis, extends through the remaining more easterly part of that constellation, and terminates between 2° to 3° to the south of γ Virginis. Venus will be in conjunction with Jupiter at 7 a.m. on the 6th; with Mercury (as stated above) at 5 p.m. on the 8th; and with Uranus at 2 p.m. on the 24th.

### The Night Sky

Is, for the purposes of the observer, a perfect blank,

### Mars, Jupiter, Saturn, Uranus, and Neptune

being all so placed as to be inacessible for observation with the telescope.

### Shooting Stars.

On the nights from the 9th to the 11th inclusive, watch should be kept for that most familiar of all showers of Shooting Stars—the "Torches" of Classical Thessaly, the "St. Lawrence's Tears," of the old Irish Catholics, and the Perseids travelling in the orbit of Comet II. 1862, of the modern meteoric astronomer. These August Meteors are notable for the trails they leave in the sky.

### Greenwich Mean Time of Southing of Nine of the Principal Fixed Stars on the Night of August 1st, 1885.

| Star. | Souths. h. | m. | s. | |
|---|---|---|---|---|
| α Ophiuchi | 8 | 47 | 9·76 | p.m. |
| γ Draconis | 9 | 11 | 26·03 | ,, |
| Vega | 9 | 50 | 26·47 | ,, |
| ζ Aquilæ | 10 | 17 | 26·95 | ,, |
| Altair | 11 | 2 | 22·66 | ,, |
| α² Capricorni | 11 | 28 | 48·55 | ,, |
| α Cygni | 11 | 54 | 34·77 | ,, |
| α Cephei | 12 | 32 | 48·89 | ,, |
| β Aquarii | 12 | 42 | 26·20 | ,, |

The method of finding the Greenwich Mean Time of Southing of either of the Stars in the above list for any other night in August, as also that of determining the local instant of its Transit at any other Station, will be found on p. 356 of Vol. XL.

## CUSWORTH'S PANORAMIC TRIPOD.

AN ingenious method of mounting a camera on a tripod has been recently brought out by Mr. C. Cusworth, of Ellington-street, N., who will shortly exhibit it on his stand at the Inventions. Tourists and those amateur photographers who desire to obtain panoramic views and quick shots at moving objects will readily appreciate the advantage of an arrangement which enables them to direct the lens in any direction without shifting the legs of the tripod. Mr. Cusworth's improved tripod consists of a wooden triangle, of any usual pattern, carrying a slightly raised disc, to which the camera is affixed by a thumb-screw. By means of a rack and pinion this disc can be rotated in either direction, so as to take in any portion of the field; the horizon may, in fact, be "swept" without disturbing the legs of the tripod. The arrangement will be appreciated at all times, but in cases where it is desired to take moving objects it will be especially valuable, as a portion of a turn of the milled head screw will at once bring an object into the field which has had time to escape from the grasp of the lens in the interval between focussing and inserting the dark slide. In many cases, too, it is not always possible to find a variety of suitable resting-places for the tripod legs; with Mr. Cusworth's arrangement, once they are firmly adjusted, the camera itself can be shifted to take in any portion of the view. As the screw which attaches the camera to the tripod is carried with the former, there is no risk of leaving it behind and finding it missing when it is most required.

## LUMINOUS PAINT.

AS several processes for the manufacture of luminous paint have been patented within recent years, both in this country and America, the following particulars may be useful to those who are looking for something better than the preparations now in the market. A phosphorescent mixture, or luminous paint, is an old discovery, but the means of applying it as a permanent paint were discovered by W. H. Balmain. Balmain's invention was patented in England in 1877, and in the United States in 1882. The invention consists in a luminous paint, the body of which is a phosphorescent compound, or is composed in part of such a compound, and the vehicle of which is such as is used as the vehicle in ordinary paint compounds—viz., one which becomes dry by evaporation or oxidation. The object or article to which such paint or varnish or wash is applied is itself rendered visible in the darkest place, and, more or less, capable of imparting light to other objects, so as to render them visible also. The phosphorescent substance found most suitable for the purpose is a compound obtained by simply heating together a mixture of lime and sulphur, or carbonate of lime and sulphur, or some of the various substances containing in themselves both lime and sulphur—such, for example, as alabaster, gypsum, and the like—with carbon or other agent to remove a portion of the oxygen contained in them, or by heating lime or carbonate of lime in a gas or vapour containing sulphur. The vehicle to be used for the luminous paint must be one which will dry by evaporation or oxidation, in order that the paint may not become soft or fluid by heat or be liable to be easily rubbed off by accident or use from the articles to which it has been applied. It may be any of the vehicles commonly used in oil-painting or any of those commonly used in what is known as "distemper" painting or whitewashing, according to the place or purpose in or for which the paint is to be used.

It is found that the best results are obtained by mixing the phosphorescent substance with a colourless varnish made with mastic or other resinous body and turpentine or spirit, making the paint as thick as convenient to apply with a brush, and with as much turpentine or spirit as can be added without impairing the required thickness. Good results may, however, be obtained with drying oils, spirit varnishes, gums, pastes, sizes, and gelatine solutions of every description, the choice being varied to meet the object in view or the nature of the article in hand. The mode of applying the paint, varnish, or wash will also depend upon the circumstances of the case. For example, it may be applied by a brush, as in ordinary painting, or by dipping or steeping the article in the paint, varnish, or wash; or a block or type may be used to advantage, as in calico-printing and the like. For outdoor work, or wherever the surface illuminated is exposed to the vicissitudes of weather or to injury from mechanical contingencies, it is desirable to cover it with glass, or, if the article will admit of it, to glaze it over with a flux, as in enamelling, or as in ordinary pottery, and this may be accomplished without injury to the effect, even when the flux or glaze requires a red heat for fusion.

In order to produce and maintain the phosphorescent light, full sunshine is not necessary, but, on the contrary, is undesirable. The illumination is best started by leaving the article or surface exposed for a short time to ordinary daylight or even artificial light, which need not be strong in order to make the illumination continue for many hours, even twenty hours, without the necessity of renewed exposure.

A. Krause, of Buffalo, N.Y., obtained a patent for improvement in phosphorescent substance dated December 30th, 1879. The patentee says: This invention relates to a substance which, by exposure to direct or indirect sunlight, or to artificial light, is so affected or brought into such a peculiar condition that it will emit rays of light or become luminous in the dark. It is a well-known fact that various bodies and compositions of matter, more especially compositions containing sulphur in combination with earthy salts, possess the property of emitting rays of light in the dark after having been exposed to sunlight. All of these bodies and compositions of matter are, however, not well adapted for practical purposes, because the light emitted by them is either too feeble to be of any practicable utility, or because the luminous condition is not of sufficient duration, or because the substances are decomposed by exposure to the atmosphere. Among the materials which have been employed with the best results for producing these luminous compositions are seashells, especially oyster shells. I have found by practical experiments that only the inner surface of these shells is of considerable value in the production of luminous compositions, while the body of the shell, although substantially of the same chemical composition, does not, to any appreciable extent, aid in producing the desired result. It follows from this observation that the smallest shells, which contain the largest surface as compared with their cubic contents, will be best adapted for this purpose. I have found that chalk, which is composed of the shells of microscopic animals, possesses the desired property in the highest degree; and my invention consists, therefore, of a luminous substance composed of such chalk, sulphur, and bismuth as will be hereinafter fully set forth.

In preparing my improved composition, I take cleaned or precipitated chalk, and subject it to the process of calcination in a suitable crucible over a clear coal or charcoal fire for three or four hours, or thereabouts. I then add to the calcined chalk about one-third of its weight of sulphur, and heat the mixture for from 45 to 90 minutes, or thereabouts. A small quantity of bismuth, in the proportion of about 1 per cent. or less of the mixture, is added together with the sulphur. The metal may be introduced in the metallic form in the shape of fillings, or in the form of a carbonate, sulphuret, sulphate, or sulphide or oxide, as may be most convenient. The substance produced in this manner possesses the property of emitting light in the dark in a very high degree. An exposure to light of a very short durtion, sometimes but for a moment, will cause the substance to become luminous and to remain in this luminous condition, under favourable circumstances, for upwards of twenty-four hours. The intensity of the light emitted by this composition after exposure is considerable, and largely greater than the light produced by any of the substances heretofore known. The substance may be ground with oil and used like ordinary paint; or it may be ground with any suitable varnish or be mixed in the manner of water colours; or it may be employed in any other suitable and well-known manner in which paints are employed.

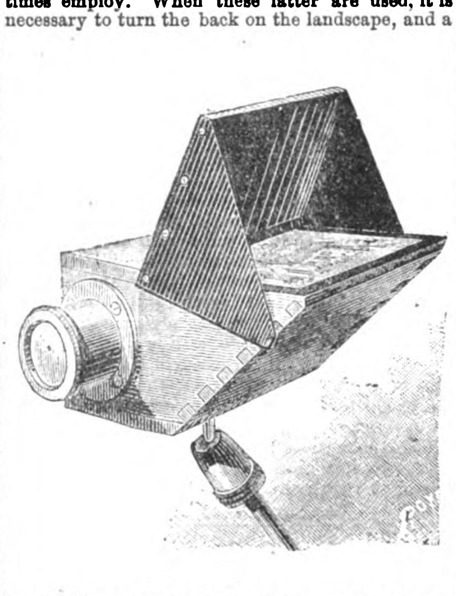
Merrill B. Sherwood, jun., of Buffalo, N.Y., obtained a patent for a phosphorescent composition, dated August 9, 1881. The author says: My invention relates to an improvement in phosphorescent illuminants. I have taken advantage of the peculiar property which obtains in many bodies of absorbing light during the day and emitting it during the night time. The object of my invention is the preparation by a prescribed formula of a composition embodying one of the well-known phosphorescent substances above referred to, which will be applicable to many practical uses. With this end in view my invention consists in a phosphorescent composition in which the chief illuminating element is monosulphide of calcium. The composition obtained by the formula may be used either in a powdered condition by dusting it over articles previously coated, in whole or in part, with an adhesive substance, or it may be intimately mixed with paints, inks, or varnishes, serving as vehicles for its application, and in this way be applied to bodies to render them luminous. The formula for obtaining the composition is as follows: To one hundred parts of unslaked lime (that obtained from calcined oyster shells producing the best results) add five parts of carbonate of magnesia and five parts of ground silex. Introduce these elements into a graphite or fireclay crucible containing forty parts of sulphur and twenty-five parts of charcoal, raise the whole mass nearly or quite to a white heat, remove from the fire, allow it to cool slowly, and, when it is cold or sufficiently lowered in temperature to be conveniently handled, remove it from the crucible and grind it. The method of reducing the composition will depend upon the mode of its use. If it is to be applied as a loose powder by the dusting process, it should be simply ground dry; but if it is to be mixed with paint or other similar substance, it should be ground with linseed or other suitable oil. In heating the elements aforesaid, certain chemical combinations will have to take place, and monosulphide of calcium, combined with carbonate of lime, magnesia, and silex, will be the result of such ignition. If, in the firing of the elements, as above set forth, all of the charcoal does not unite with the other elements, such uncombined portion should be removed from the fused mass before it is ground. If it is designed to mix the composition with paints, those composed of zinc-white and baryta should be chosen in preference to those composed of white lead and coloured by vegetable matter, as chemical action will take place between the composition and paint last mentioned, and its colour will be destroyed or changed by the gradual action of the sulphureted hydrogen produced. However, by the addition of a weak solution of gum in alcohol or other suitable sizing to the composition, it may be used with paints containing elements sensitive to sulphureted hydrogen without danger of decomposing them and destroying their colour.

In many and possibly in a majority of cases the illuminating composition applied as a dry powder will give the most satisfactory results, in view of the tendency to chemical action between the paint and composition when intimately mixed; in view of the fact that by the addition to paint of any colour of a sufficient quantity of the composition to render the product luminous, the original colour of the paint will be modified or destroyed; and also, in view of the fact that the illuminating composition is so greatly in excess of the paint, the proportions in which they are united being substantially ten parts of the former to one of the latter, it will be difficult to impart a particular colour to the product of the union without detracting from its luminosity. On the other hand, the union of dry powder with a body already painted by the simple force of adhesion does not establish a sufficiently intimate relation between it and the paint to cause chemical action, the application of a light coat of powder does not materially change the colour of the article to which it is applied; and, further, by the use of the powder in an uncombined state its greatest illuminating effects are obtained. Again, if the appearance in the daytime of the article which it is desired to have appear luminous at night is not material, it may be left unpainted and simply sized to retain the powder.

Orlando Thowless, of Newark, N.J., obtained a patent for a process of manufacturing phosphorescent substances, dated November 8, 1881. The inventor says: The object of my invention is to manufacture phosphorescent materials of intense luminosity at low cost and little loss of materials. I first take clam shells, and after cleaning place them in a solution composed of about one part of commercial nitric acid and three parts of water, in which the shells are allowed to remain about twenty minutes. The shells are then to be well rinsed in water, placed in a crucible, and heated to a red heat for about four hours. They are then removed and placed, while still red-hot, in a saturated solution of sea-salt, from which they are immediately removed and dried. After this treatment and exposure to light the shells will have a blood-red luminous appearance in the dark. The shells thus prepared are used with sulphur and the phosphide and sulphide of calcium to produce a phosphorescent composition, as follows:—One hundred parts, by weight, of the shells, prepared as above, are intimately mixed with twenty parts, by weight, of sulphur. This mixture is placed in a crucible, or retort, and heated to a white heat for four or five hours, when it is to be removed, and forty parts more of sulphur, one and one-half parts of calcium phosphide, and one-half part of chemically pure sulphide of calcium added. The mixture is then heated for about ninety minutes to an extreme white heat. When cold, and after exposure to light, this mixture will become luminous. Instead of these two ignitions, the same object may be in a measure accomplished by the addition of the full amount of sulphur with the phosphide and sulphide of calcium and raising it to a white heat but once. The calcium phosphide is prepared by igniting phosphorus in connection with newly-slaked lime made chemically pure by calcination. The condition of the shells when the sulphur is added is not material; but the heat renders them porous and without moisture, so that they will absorb the salt to as great an extent as possible. Where calcined shells are mixed with solid salt, the absorbing power of the shells is greatly diminished by the necessary exposure, and there will be a lack of uniformity in the saturation. On the contrary, by plunging the red-hot shells in the saline solution the greatest uniformity is attained.

## THE MONITOGRAPH.

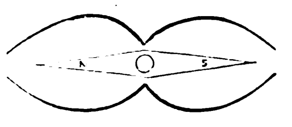
THE apparatus shown in the accompanying cut is a small improved camera obscura, which may be advantageously used as a substitute for the black convex mirrors that landscape painters sometimes employ. When these latter are used, it is necessary to turn the back on the landscape, and a reversed image is obtained. Again, as the glass is black, so as to prevent double refraction, the scale of tones is not accurate, and furnishes very disadvantageous data to the painter.



With the *monitograph*, which the artist may affix to the easel that supports his picture, we get a reduced image, but one that is very accurate in all its details. The apparatus is placed to the right of the artist, who thus has before his eyes the scene that he wishes to represent, while at the same time the reduced image is not reversed on the ground glass. The luminous intensity of the image is equal, and the tones are true to nature and may be reproduced upon the canvas. The apparatus is very light (weighing but 8oz.), and is therefore easily carried. It is mounted upon a rod that has a rotary motion, and that terminates beneath in a foot that may be fixed by screws to one of the legs of the easel. The image forms upon a sheet of ground glass, over which projects a black screen. This latter, which pivots upon on axis, shuts down upon the ground glass when the apparatus is prepared for carriage, and thus reduces the bulk of the whole and prevents the glass from being broken. The image obtained is very small, since it is formed upon a square surface whose sides scarcely exceed 2in.; but, as small as it is, it is very sharp and very luminous, and suffices to give the masses in general, and even the smallest details. The apparatus contains two total reflection prisms, one of which has its principal apex directed upward, and the other one its principal apex directed horizontally. The first reflects the image given by the lenses of the objective horizontally, and the second reflects it vertically to the ground glass. We have experimented with this apparatus, says *La Nature*, and found it to give good results. We noticed that there was no spherical aberration in it, and no refrangibility. We believe that it is capable of rendering genuine service to landscape painters and to staff officers who desire to obtain the general contour of a piece of ground. The apparatus is the invention of M. Marius Mallen, and is constructed by the well-known optician, M. F. L. Chevalier, of Paris.

## GAIFFE'S NEW MEDICAL GALVANOMETER.

IN this apparatus, which contains but one needle, and has no directing magnet, proportionability between the intensities and deflections is obtained by means of a special form given to the frame upon which the wire is wound. We give herewith a figure of the curve that Mr. Gaiffe has fixed upon after numerous experiments.



Upon examination it will be seen that the needle approaches the current in measure as the directing action of the earth increases; and experiment proves that the two actions counterbalance each other, and render the deflections very sensibly proportional to the intensities up to an angle of from 65 to 75 degrees. Another important fact has likewise been ascertained, and that is that, under such circumstances, the magnetic intensity of the needle may change without the indications ceasing to have the same exactness up to 65 degrees. As is well known, Mr. Desains has demonstrated that this occurs likewise in sinus or tangent galvanometers; but these have helices that are very large in proportion to the needle. In medical galvanometers the proportions are no longer the same, and the needle is always very near the directing helix. If this latter is square, or even elliptical, it is found that, beyond an angle of 15 degrees, there are differences of four or five degrees in the indications given with the same intensity of current by the same needle, according to the latter's intensity of magnetism. This inconvenience is quite grave, for it often happens that a needle changes magnetic intensity, either under the influence of too strong currents sent into the apparatus, or of other magnets in its vicinity, or as a consequence of the bad quality of the steel, &c. It was, therefore, urgently required that this should be remedied, and from this point of view the new mode of winding the wire is an important improvement introduced into medical galvanometers.—*La Lumière Electrique.*

## COLOURED GLASS AND ARTIFICIAL GEMS.

THE metallic oxides when mixed with any of the glasses dissolve in them with ease at a melting heat, and always change the colour more or less, sometimes producing very beautiful compounds, which, when well prepared, have a lustre and richness of colour strongly resembling the natural gems, though in an inferior degree. The business of making these coloured glasses and artificial gems is carried on to a very great extent in the manufacture of a variety of articles, and, though some of the management remains a secret in the hands of the artists, a good deal of valuable matter has been made public by the labours of Neri, Kunckel, Margraaf, Fontanieu, and many other practical chemists. It is very easy for any person at all used to chemical experiments to repeat most of these in the small way, with sufficient success to satisfy himself of the leading facts, though for the purpose of manufacture more care in the choice and preparation of the materials and a greater length of time in the melting part is required than most experimenters choose to bestow. It may be premised too that the art of making coloured enamels is essentially the same as that of coloured glasses, the chief difference being that in the former case the ground or vitreous substance that receives the colour is an opaque enamel glass, and in the latter a clear transparent glass. The colouring power of the metallic oxides is also in many instances much affected by the degree of heat to which they are exposed, and to the other ingredients with which they are mixed, and hence arise a good many precautions and niceties of management, many of which are only known to the practical artist. There seems good reason to suppose that much of this difference depends on the degree of oxygenation in which the colouring oxide is left after the action of fire, or of the other ingredients. The phenomena that occur in the use of manganese will hereafter be described, and something familiar happens in using the oxides of iron and silver. Sometimes a metallic oxide may be so nearly reduced to the reguline state as not to be perfectly soluble in the glass, but only suspended in it. This happens occasionally with the oxide of copper, which, when perfectly oxidised, gives a fine bluish-green, but when nearly in the metallic state produces a brown-red and not perfectly transparent glass. There is also a mutual action of the oxides upon each other, so that the glasses in which oxide of lead enters will not receive a red colour by iron, an effect which is produced with the merely alkaline glasses. Much remains to be done on this very curious and entertaining subject of the colouring power of metallic oxides, and it is only by a well-conducted scientific series of experiments that the perplexing intricacy of many of the receipts of the articles on this subject can be reduced to certain rules.

In making coloured glasses to resemble artificial gems, the glass which is to receive the colour (which is often called crystal) ought to unite the qualities of great purity, lustre, and hardness, together with a sufficient fusibility to melt at a moderate heat those oxides that are in danger of being decomposed by a high temperature. A vast variety of receipts have been given for such a glass, and it appears that several sorts are actually in use according to the price and object of the manufactured article. The glasses that possess the greatest lustre, and are at the same time easily fusible, are unquestionably those in which the oxide of lead enters very largely, and it appears that many of them are little else than oxide of lead vitrified with a much smaller proportion of silex than is used even in flint glass, or any other species. To these borax is an important addition, and often arsenic and other fluxes are added. But it unfortunately happens that the lead glasses are at the same time the softest, and scratch with the greatest ease. Hence it is the perfection of this art to find a compound, or manage any of the known compounds, in such a manner as to unite both lustre and hardness; in the former, the natural gems (the diamond excepted) may be very nearly equalled, but not in the latter.

Many of the oldest artists have had the idea that a harder glass would be obtained by making rock crystal the silicious basis than sand, flint, or any other stone of this genus. But this seems totally unfounded, for when once dissolved in a flux of any kind, the hardness of rock crystal is irrevocably lost, as it is not an inherent property of this particular species any otherwise than as depending upon its natural aggregation, which of course is destroyed. Perhaps it may be somewhat purer than the finest sand, or than powdered gun-flints, since these (the latter, at least, certainly) contain a very minute portion of iron, which possibly, though not very probably, may a little affect the very finest colours. It is rendered friable by being heated red hot and quenched in water the same way that gun-flints are. It should then be ground in a hard stone mortar, or in a mill, and not in any metallic mortar.

A few of these glasses may be here given from the directions of M. Fontanieu:—

No. 1. Mix 20 parts of litharge, 12 of silex, 4 of nitre, 4 of borax, and 2 of white arsenic, frit them in a crucible and afterwards melt, then pour the whole into water, separate any revived lead that may be found, and melt again.

No. 2. Mix 20 parts of cerusse, 8 of silex, 4 of carbonate of potash, and 2 of borax. When melted, pour into water, and re-melt in a clean crucible.

No. 3. Mix 16 parts of minium, 8 of rock crystal in powder, 4 of nitre, and 4 of carbonate of potash; melt and re-melt as before.

No. 4. Treat as above, 24 parts of borax, 8 parts of rock crystal, and 8 parts of carbonate of potash.

No. 5. Make a quantity of liquor of flints by fritting together 3 parts of alkali with 1 of rock crystal, which dissolve in water, and saturate with dilute nitric acid. Edulcorate and dry the silex, which precipitates, and which is then in a very fine impalpable powder. Then melt in a crucible with 1½ its weight of very fine cerusse, and pour the glass into water. Then break it down and melt it with one-twelfth its weight of borax, and pour into water as before. Lastly, melt this latter product with one-twelfth of nitre, and the result will be a very fine hard glass of extreme lustre.

Of the above glasses, No. 1, says the *Pottery and Glassware Reporter*, will be extremely soft and fusible, on account of the large proportion of flux, and it requires a very good crucible to withstand the corroding effect for a number of hours. The crucibles are found to stand better if they are first lined with any common glass without lead, for which purpose a little of the glass, No. 4, may be moistened with the water, rubbed over the inside of the crucible, slowly and thoroughly dried, and heated red hot before the mixture is added, which will give it a uniform glazing. Silex requires to make a perfect and sufficiently workable glass from 1½ to twice its weight of oxide of lead; and a glass of this kind with a smaller quantity of oxide of lead and a little other flux will be very hard and brilliant, and will imitate the diamond when properly set more that most other compositions.

The length of time required for fusion of the coloured glasses appears to be for the hard glasses or pastes at least twenty-four hours, but the softer mixtures are thoroughly complete in a few hours. In the glass, No. 4, the silex is first directed to be reduced to the state of the greatest purity, and the most impalpable powder, by previous fusion with an excess of alkali, and precipitation by an excess of acid. It is seldom, however, that such extreme nicety of preparation can be required, and probably finely powdered flints would answer as well, or even fine sand. The process of pouring the melted glass into water and remelting is used to mix the ingredients thoroughly, and is found by experience to have its use.

### Turquoise Blue Glass.

The *Sprechsaal* remarks that the manufacture of blue glass and glass fluxes by means of oxide of copper was known to the Egyptians in the oldest times, and was connected with the glazing of earthenware, &c. Specimens of this class of work are to be found in numerous museums, &c., the blue being, in most cases, turquoise blue, and the glaze is free from cracks, mostly in consequence of the body to which it was applied being of a suitable character. These glazes are not transparent, but slightly opaque. Among the discoveries of ancient Rhodian ceramic ware there are specimens of this glaze in conjunction with other colours.

It would seem that the art of making blue glass with the oxide of copper was never totally lost. Merett, Neri, and Kunckel give recipes for blue alabaster glasses from copper ash. According to the analysis of Borgstede, such a blue alabaster glass would be compared as follows:—

| | |
|---|---|
| Silicic acid | 82·95 |
| Alumina and oxide of iron | ·27 |
| Lime | ·08 |
| Potash | 16·08 |
| Oxide of copper | ·56 |
| | 99·84 |

This analysis would correspond with the following smelting composition:—

| | |
|---|---|
| Washed white quartz sand | 100· |
| Double purified potash | 29· |
| Black oxide of copper | 0 560 |

Chemically regarded, this substance is only silicate of potassium, which is super-saturated with silicic acid, and is coloured blue with some oxy-silicate of copper. This alabaster glass cannot be considered a real glass, for boiling in water would change it to a kind of soluble glass. Its external appearance is that of real glass, in which the separation of superfluous silicic acid (during cooling, after it had been previously completely dissolved in melting silicate of potassium) had brought about an opacity resembling that of alabaster.

Starting from the supposition that lead glasses are coloured green with oxide of copper, it is asserted that the potassium which (in some recipes) is introduced into the glass composition in the form of potash and saltpetre produces the blue colour. Silicate of potassium (for instance, potash and quartz sand melted together) will not make a real glass, but only a soluble glass, which is dissolved by boiling in water.

Besides silicate of potassium, silicate of sodium (made from soda) has the property of giving, with oxide of copper, blue or turquoise blue glass. It should not, however, be introduced under the quantitative conditions as silicate of potassium, as its chemical equivalent is smaller, and thus a composition with silicate is differently prepared from one with saltpetre. To render turquoise glass harder and more resisting, a further quantity of lime or silicate of lime must be added. Baryta can be used instead of lime, but it renders the glass more easily fusible. It is recommended to introduce baryta in the form of witherite (carbonate of baryta), which is relatively pure. The presence of iron in small quantities is no disadvantage. The action of magnesia is supposed to be the same as that of lime, but its small chemical equivalent should always be taken into consideration. The form of the oxide of copper (whether oxide of copper, copper ash, or carbonate of copper) is immaterial for the preparation of turquoise blue; it being understood that the various substances are free from impurity, and are employed in the right quantities. It is further remarked that with the increase of oxide of copper the intensity of the azure colouring in fluxes rich in alkali varies up to a certain low limit of percentage of the copper oxide. On the other hand, green again enters into the blue beyond this limit, and increases in proportion to the augmentation of the colouring substance.

## THE TRANSMUTATION OF ELEMENTS.

IN modern times it has always been held as one of the fundamental principles of chemistry that those bodies commonly called elements are unchangeable, and absolutely separate kinds of matter. The old alchemists, on the contrary, believed it quite possible to change one metal into another; and the greater part of their labours was devoted to finding some way of transmuting mercury into gold. Several, indeed, claimed that they had discovered the secret; but, like the inventor of the Keely motor, some little "adjustment" always remained to be perfected, which required a little of the precious metal obtained in the old-fashioned way of digging from the ground. Queen Elizabeth, when shown a piece of silver said to have been made from a piece of a brass warming pan, expressed her great interest in the discovery, but hinted that any one who could produce the precious metal so easily could have no possible need of aid from the royal treasury.

Were the old alchemists altogether in the wrong? or is there still some ground for the belief that the substances we call elements are really modifications of one primitive form of matter? It is not improbable that some of the elements are really compound bodies, and that by more thorough methods of analysis we may be able to discover their component parts. Take the element iron, for example. It forms two distinct series of chemical compounds—the ferrous and ferric, which differ from each other in their chemical reactions; and if they could not both be reduced to the same metallic iron we should be justified in considering them as compounds of two different elements. Many other metals show this same peculiarity. The allotropic forms of some elements have a bearing on this question. The diamond and charcoal are both forms of the same element, carbon. Both, when burned, form carbonic dioxide; but in every other respect they are totally distinct. Oxygen in the state of ozone is an entirely different body from the ordinary oxygen gas, but the chemist can find nothing but oxygen in either. If ozone and oxygen are only different forms of the same element, is it not possible that oxygen and chlorine, for instance, may be found to have a common origin? And if it could be shown that oxygen and chlorine could be changed into each other, why not mercury and gold, as the alchemists believed?

The recently discovered "periodic law" of the elements must not be forgotten in this connection. It is found that when the elements are arranged in the order of their atomic weights they form regular groups, closely related to each other in their chemical and physical characteristics. There are gaps in this series which will probably be filled by elements yet to be discovered. One such gap has already been filled by the element gallium, the properties of which were quite accurately predicted before its discovery, from the position of the vacant space of the series.

All these facts certainly show a connection of some kind between the elements; but what it is we do not yet know, and we must wait patiently for the results of future investigations. It must be remembered that as yet we have no actual proof whatever of the possibility of changing one element into another, or even of referring them all to one primary form of matter. We may treat iron or oxygen in any way we please, but as yet nothing but iron or oxygen has been produced from them; carbon is still nothing but carbon, whether in the form of coal, graphite, or diamond; and, although our more recent discoveries in chemistry and physics hint to us that perhaps the ideas of the mediæval scientists were not quite so absurd as they would have been considered fifty years ago, yet for the present we must retain the generally accepted ideas in regard to the individuality of the so-called elementary bodies.

There is a rich field in this direction for the scientific investigator. The tendency in all schools of chemistry at present seems to be towards the study of organic compounds, to the neglect of the equally important inorganic bodies. While the study of organic chemistry has certainly led to the most brilliant results, yet we can but feel that the field for discovery in inorganic chemistry is still as wide as in the days of Davy and Faraday, and will yield equally rich returns to the careful and patient investigator.—*Popular Science News.*

## A NEW STANDARD CELL.[*]

SINCE October last I have made some experiments on the zinc-alkali-copper oxide cell, with a view to determine the practicability of some modification of it. The fact that copper and iron, and perhaps some other metals, dissolve in potassium (or sodium) hydrate when used as cathodes suggested to me the possibility that the formation of the alkaline cuprate might occur at a definite and practically convenient difference of potential between the electrodes immersed in the alkaline bath. As a matter of fact, I find that a cell mounted with amalgamated zinc, potassic hydrate, and metallic copper gives, when charged until a blue colour appears, a deflection of 170 divisions on the scale of a Thomson galvanometer; the Daniell, mounted with saturated zinc sulphate and copper sulphate, giving 156 divisions. The zinc-alkali-copper cell is joined by a double key to charging cells and to the galvanometer, a resistance of over 9,000 ohms. being included in the circuit of the latter. The proper shunt is, of course, employed. This deflection of 170 divisions seems to be invariable, and the cell experimented upon promises to be a desirable practical standard of electromotive force. Its excellence appears to consist in the fact that the cuprate produced breaks up before it diffuses to the amalgamated zinc, depositing oxide of copper, which settles. The zinc is suspended about an inch above the copper—which is a spiral ribbon, exposing about two square feet of surface—and the resistance is less than an ohm. I have used a 10 per cent. solution of "depurated" potassic hydrate. After some trials it is found that the shifting of the cell from the charging source to the galvanometer circuit may be done leisurely, as the electromotive force does not seem to begin to fall off for some minutes. Further testing of the effect of changes of temperature, strength of solution, &c., is in progress. Thus far the temperature of the cell has been allowed to vary very little, not enough to affect the readings. I offer this preliminary note as of possible interest to your readers. This type of cell would be admirably adapted to furnish any desired multiple of its electromotive force.

# ON THE COLOUR-CORRECTION OF ACHROMATIC TELESCOPES.

A Reply to Prof. Chas. S. Hastings, by Wm. Harkness.*

In the December number of this journal, pages 434 and 435, the distinguished Associate Professor of Physics of the Johns Hopkins University has criticised my theory of the colour-correction of achromatic telescopes in language which I quote here to avoid the possibility of misrepresenting it, merely adding numbers to the clauses for convenience of reference:—

"These results are directly opposed to those of a recent writer in this journal (Prof. Harkness, in the Sept. number, pp. 191-193); but his conclusions arise from erroneous calculations. (I.) Not only does his interpretation of his equation (12) imply the manifest absurdity that in a system of infinitely thin lenses in contact, its properties are determined by the order of the lenses, but the interpretation is impossible. True, $A_2$ should have an opposite sign to $A_1 + A_3$; but that asserts nothing as to likeness of the latter symbols in sign. (II.) Thus, $n$ in equation (16) may be negative, and, consequently, his subsequent reasoning is fallacious, for in that case $n$ does not have to be infinite to cause equation (27) to vanish. (III.) I may add that the origin of the confusion is in making the ratio $D \div E$ in equation (9) constant; it may be, and, of course, should be, indeterminate.

"(IV.) Prof. Harkness has made another mistake, founded upon inadequate experiment, which has so important a bearing on the theory of the double objective that it should not be allowed to pass uncorrected. His statement (p. 191) concerning the condition for colour-correction is substantially correct, though, in my opinion, it is not self-evident, but requires proof. This proof I shall supply in a forthcoming number of the *American Journal of Mathematics*. (V.) His experiment, however (p. 193), directly contravenes this principle, for he finds that the focal plane does not correspond to the minimum focal distance, but to something greater. (VI.) The source of error is the introduction of a variable element in the system—viz., the eye, which would adjust itself differently in observing the star and its spectrum. Had the writer used eyepieces of successively higher power, thus lessening progressively the power of accommodation of the system with his prism he would have seen his points $\gamma_m$ and $\gamma_n$ approach until they sensibly coincided; or better still, had he formed his spectrum by a grating (such as perforated cardboard) before the objective, instead of by a prism between the ocular and eye, he could not have been misled, since the uncoloured image would serve to control the eye."

"(VII.) Finally, the fourth conclusion (p. 196) is strictly true, though we are not to conclude, as would seem from the text, that the detriment due to secondary spectrum depends either solely upon the aperture, or varies conversely as the focal length. . . ."

Let us examine this criticism in detail, referring to its clauses, and to the equations of my original paper, by their respective numbers.

Clause I. virtually asserts that three quantities can be arranged in two classes otherwise than by putting one in one class, and two in the other. To prove this, we remark that equation (12) may be written

$$O = A_1 (b_1 + 2c_1 \gamma_0^2) + A_2 (b_2 + 2c_2 \gamma_0^2) + A_3 (b_3 + 2c_3 y_0^2) \ldots. (36)$$

For all glasses of which I have any knowledge, $b$ is positive and very much larger than $c$. This latter quantity is sometimes negative; but when this happens it is exceedingly small. $\gamma$ cannot be otherwise than positive. From these conditions it results that the quantities $(b + 2c \gamma_0^2)$ are invariably positive, and therefore the sign of each term in (36) depends solely upon the sign of its A. But in order that (36) may be true, one of its terms must have a different sign from the other two; and just because the properties of a system of infinitely thin lenses in contact are independent of the order of the lenses; the choice of this term is arbitrary. Taking advantage of this circumstance to follow the usual practice of opticians, I made the middle lens different from the other two, and wrote

$$-A_2 (b_2 + 2 c_2 \gamma_0^2) = A_1 (b_1 + 2 c_1 \gamma_0^2) + A_3 (b_3 + 2 c_3 \gamma_0^2) \ldots\ldots\ldots (37)$$

But Clause I. declares, "True, $A_2$ should have an opposite sign to $A_1 + A_3$; but that asserts nothing as to likeness of the latter symbols in sign." A statement which is manifestly untrue, unless it can be shown that three quantities can be arranged in two classes otherwise than by putting one in one class and two in the other.

Clause II. asserts that $n$, in equation (16), may be negative. This is absurd, because $n = A_3 \div A_1$, and it has just been shown that the signs of $A_1$ and $A_3$ are always similar.

Clause III. declares that $D \div E$ should be indeterminate; and that all my alleged errors arise from making it constant. Referring to equations (6) we see that—

$$\begin{aligned} D &= A_1 b_1 + A_2 b_2 + A_3 b_3 \\ E &= A_1 c_1 + A_2 c_2 + A_3 c_3 \end{aligned} \quad \ldots\ldots\ldots\ldots (6)$$

The A's depend only upon the curves of the lenses, while the $b$'s and $c$'s depend only upon the physical properties of the glasses employed. In designing an objective D and E are both so far arbitrary that any glasses and any curves may be chosen; but when the objective is completed, I certainly do hold that its curves and the physical properties of the pieces of glass composing it are constant. If I am right in this, it follows that both D and E, and also their ratio, are constant; Clause III. to the contrary, notwithstanding.

Clause IV. admits the accuracy of my statement that an objective is properly corrected for any given purpose when its minimum focal distance corresponds to rays of the wave-length which is most efficient for that purpose, but says the statement requires proof, and is not self-evident. With the law of dispersion assumed in equation (2), the focal curve can have but one tangent parallel to the axis of abscissas; and I did not suppose it necessary to tell the readers of this Journal that the parts of such a curve nearest the tangent line are those adjacent to the point of tangency. That consideration proves my proposition, and it is so elementary that I thought it self-evident. If more than two lenses and a dispersion formula involving more than two powers of the wave-length are assumed, I venture to say that the condition for coleur-correction stated above cannot be proved. It may be true in special cases; but in general the focal curve will have such a form as to give more than one minimum focal distance.

Clause V. involves the assumption that the focal plane must be tangent to the focal curve at the point where the latter makes its nearest approach to the objective. No reason is assigned for this, and I do not believe any exists.

Clause VI. virtually asserts that the focal distance of an objective is a function of the power of its ocular. For all astronomical instruments carrying filar micrometers, the first business of the observer is to place the wires accurately in the focus of the objective. This once done they are not again disturbed, unless to make some radical change in the instrument. A dozen eyepieces may be used in the course of a single evening; but no matter what their power, when they are focussed upon the wires they are always found to be focussed upon the objective. Hence the focal plane always coincides with the wires. But the plane of the wires is fixed, and the focal curve, as I have defined it, is also fixed. Consequently the points of intersection of the focal plane with the focal curve are fixed, and the universal experience of astronomers demonstrates that the positions of the points $\gamma m$ and $\gamma n$ do not vary with the form of the ocular.

As Clause VII. affirms the correctness of my fourth conclusion, it is only necessary to express my thanks for such an endorsement; but I cannot refrain from adding that since this clause rests upon equations condemned by my critic, there may be people wicked enough to inquire how these erroneous equations finally led to a correct result.

In this connection it is desirable to state that some months ago I investigated the relations existing in achromatic objectives between aperture, focal length, and secondary spectrum. As the admissible limits of the latter of these elements is arbitrary, it is not possible to fix absolutely the relations between the other two; but I believe the focal distance should rarely be less than that given by the formula—

$$F = (9{\cdot}04\, a^2 + 1296)^{\frac{1}{2}} - 36 \ldots\ldots\ldots\ldots\ldots\ldots (38)$$

in which F is the focal distance, in feet; and $a$ the clear aperture in inches. For small apertures the foci given by this expression are inconveniently short; while for large apertures they considerably exceed those in general use.

Now consider a system of infinitely thin lenses in contact, and let us inquire how many lenses are needed in the system to bring the greatest possible number of light rays of different degrees of refrangibility to a common focus with any given law of dispersion.

For this purpose we revert to equation (5), which may be written—

$$f^{-1} = (\mu_1 - 1) A + (\mu_2 - 1) A_2 + (\mu_3 - 1) A_3 + \&c. \ldots\ldots\ldots (39)$$

the number of terms being unlimited. For the dispersion formula we write—

$$\mu = \phi (\lambda)$$

The form of $\phi (\lambda)$ is regarded as unknown; but there will be no loss of generality if it is developed in a series arranged according to the powers of $\lambda$. We therefore have—

$$\mu = a + b \lambda^m + c \lambda^n + e \lambda^p + \&c. \ldots\ldots (41.)$$

in which $a$, $b$, $c$, &c., are constants, and the number of terms may be taken as great as is desired. Also, let us put—

$$\begin{aligned} C &= A_1 (a_1 - 1) + A_2 (a_2 - 1) + A_3 (a_3 - 1) + \&c. \\ D &= A_1\, b_1 + A_2\, b_2 + A_3\, b_3 + \&c. \\ E &= A_1\, c_1 + A_2\, c_2 + A_3\, c_3 + \&c. \\ F &= A_1\, e_1 + A_2\, e_2 + A_3\, e_3 + \&c. \end{aligned} \quad \ldots\ldots\ldots\ldots (42).$$

The number of these equations and the number of terms in the right-hand member of each of them being the same as the number of terms in the right-hand member of (41). Then by a simple transformation (39) becomes—

$$f^{-1} = C + D \lambda^m + E \lambda^n + F \lambda^p + \&c. \ldots (43.)$$

This is the equation of the focal curve; $\lambda$ being the abscissa and $f$ the ordinate. Its first derivative is—

$$\frac{d f}{d \lambda} = - f^2 (m D \lambda^{m-1} + n E \gamma^{n-1} + p F \lambda^{p-1} + \&c. \ldots\ldots (44.)$$

which, as is well known, expresses for every point of the curve the tangent of the angle made by the tangent line with the axis of abscissas. The number of rays of different degrees of refrangibility, which can be brought to a common focus will evidently be the same as the number of times the focal plane intersects the focal curve. But the focal plane is necessarily parallel to the axis of abscissas; and, therefore, the greatest possible number of intersections of the curve with the plane can only exceed by one the number of tangents which can be drawn parallel to the axis of abscissas. To find these tangents we equate (44) to zero, and obtain—

$$o = m D + n E \lambda^{n-m} + p P \lambda^{p-m} +, \&c. \ldots. (45)$$

As $\lambda$ can never be either zero, imaginary, or negative, we have to consider only the real positive roots of this equation, each of which corresponds to a tangent. To make the number of roots as great as possible, the quantities D, E, F, &c., must be independent of each other, which will be the case when the right-hand member of the equations (42) contains as many A's as there are powers of $\lambda$ in (41). Hence it is evident that the number of real positive roots in (45) will be one less than the number of powers of $\lambda$ in (41) and we conclude that—

In any system of infinitely thin lenses in contact, the number of lenses required to bring the greatest possible number of light rays of different degrees of refrangibility to a common focus is the same as the number of different powers of $\lambda$ involved in the dispersion formula employed.

The method used in deducing this result was adopted because it exhibits clearly the geometrical relations of the problem. The result itself is evident from a mere inspection of equation (43), which cannot possess more real positive roots that it has independent co-efficients—D, E, F, &c.

The colour-correction of an objective depends only upon the form of its focal curve; which form is as much under control as the nature of the case admits when the co-efficients, D, E, F, &c., of equation (43) are independent of each other. This, taken in connection with what precedes, demonstrates that—

In an objective consisting of a system of infinitely thin lenses in contact, the colour-correction cannot be improved by increasing the number of lenses beyond the number of different powers of $\lambda$ involved in the dispersion formula employed.

This result confirms the conclusion of my former paper, in which I used a dispersion formula involving but two powers of the wave-length, and consequently found but two lenses necessary in an achromatic objective. It also throws a curious light upon the general theory of achromaticity. If the law of dispersion had been such as could be expressed by a function involving but a single power of the wave-length, there would have been no irrationality of spectra, the mean dispersive powers might have been just what they now are, and yet, Newton would have been right in saying that achromatic telescopes were an impossibility. Conversely, the greater the number of powers of the wave-lengths involved in the dispersion function, the greater the number of rays of different degrees of refrangibility which can be brought to a common focus; and this, irrespective of any irrationality which may exist in the spectra. With rational spectra, and a law of dispersion involving at least two different powers of the wave-length, a pair of lenses would suffice for the construction of a perfectly achromatic objective. In strictness, these statements apply only to objectives consisting of infinitely thin lenses in contact. Possibly they may require modification when the thicknesses and distances apart of the lenses are considered.

---

* From the *American Journal of Science*, Vol. XIX. No 110, February, 1880. See also Eng. Mechanic, present volume, page 447.

The textbooks teach that the condition of achromatism for two thin lenses in contact is

$$o = p_2 f_1 + p_1 f_2 \;\ldots\ldots\ldots\ldots\ldots \quad (46).$$

in which $f_1$ and $f_2$ are the foci, and $p_1$ and $p_2$ the dispersive powers of the lenses. They further teach that it is sufficiently accurate to put—

$$p = \frac{\delta \mu}{\mu - 1} \ldots\ldots\ldots\ldots (47)$$

in which $\delta \mu$ is the difference and $\mu$ the mean of the refractive indices for the rays D and F. For a law of dispersion involving at least two different powers of the wave-length, these equations will hold; but for a law involving only a single power of the wave-length they may be satisfied, and yet the system of lenses will not be achromatic. Instead of embodying, these equations are actually independent of the essential conditions of achromatism, which is that at least two rays of widely different wave-length must be brought to a common focus.

I have not had leisure to examine my critic's figures, nor does it seem worth while to do so. My equation (2) represents refractive indices with an accuracy of about four and a half places of decimals, while most of the authorities upon which he relies only give these quantities to five places of decimals. If this difference of five units in the fifth place of decimals can originate such changes in the focal curve as he supposes, it is evident that trustworthy conclusions can only be reached by using very accurate dispersion formulæ. Cauchy's formulæ, as written in equation (2), has hitherto been most used; but when compared with the best observations, the residuals, although small, show some constancy of sign. It has recently been claimed[*] that Briot's formula, which is

$$\mu = a + b\,\lambda^{-2} + c\,\lambda^{-4} + k\,\lambda^{2} \ldots\ldots\ldots (48)$$

represents the best observations throughout the whole space from the extreme ultra red to the extreme ultra violet within the limits of accidental error. If such is the case, a triple objective may be better than a double one; but my critic's figures certainly do not suffice to prove this. They are founded upon a formula whose independent variable is not the wave-length of the light, but the refractive index of a standard piece of glass; and his Table II., page 432, shows that, when compared with observation, this formula yields residuals exhibiting as much constancy of sign, and almost the same magnitude as those given by my equation (2). The use of any independent variable other than the wave-length is likely to produce erroneous results, and certainly does not tend to elucidate the subject.

Having seen that a dispersion formula involving only three powers of the wave-length suffices to represent the best observations, and remembering that this circumstance limits the number of lenses which can be employed with advantage in an objective to not more than three; we are now in a position to appreciate the absurdity of my critic's assertion, page 429, when inquiring if it is possible to eradicate the secondary spectrum by increasing the number of lenses in an objective, he says; "Theoretically, since a new disposable constant for colour change is introduced with each lens in the system, the answer is evidently affirmative; . . ."

For an objective consisting of more than two lenses and a law of dispersion involving more than two powers of the wave-length, the condition given in my former paper for the best colour-correction is no longer applicable. The problem then becomes very complex, but I am inclined to think that it is satisfactorily solved by attributing to each element of the focal curve a mass proportional to its efficiency, for the purpose of which the correction is required, and varying the curve until its moment of inertia about its intersection with the focal plane becomes a minimum. It is also probable that this condition will suffice to determine the relative merits of double and triple objectives; the focal curve with the smallest moment being the best.

Finally, it only remains to reiterate that the conclusions of my former paper are certainly correct to the degree of accuracy involved in my fundamental equations; that is, for a system of infinitely thin lenses in contact, and for the law of dispersion embodied in equation (2). For a different law of dispersion, or if the thicknesses and distances apart of the lenses are considered, these conclusions may require modification.

Washington, Dec. 29, 1879.

# THE NEW DOUBLE-COATED SENSITIVE PAPER.[*]

By LEON WARNERKE.

THE more photography becomes popular, so the more is felt the necessity of some good substitute for glass upon which to take a negative. It will be superfluous to assert that glass, being bulky, heavy, and brittle, is a very inconvenient material for outdoor work. A few more or less successful expedients have been proposed and tried for this purpose since collodion made glass the almost exclusive material for negatives. The question of a substitute for glass has received, however, more development since the introduction of the dry-plate process, and especially after that of collodion emulsion. I myself have been the originator of one of the systems, in which a collodion film, prepared on paper, was used as a temporary support. The introduction of gelatine emulsion for general use, with its great sensitiveneess and different physical properties of the vehicle employed, naturally necessitated a different method; and such was provided, either in the shape of a gelatine film pure and simple, or in the shape of a film temporarily attached to the paper, to be stripped off after development when dry, or in the shape of paper covered with emulsion, the image being developed and treated with hot water, as in my patent process. But the gelatine process has made the practice of photography very popular, and added a great contingent of new adepts. These use ready prepared glass plates, and get their pictures by a very simple process of development and subsequent fixing, and they naturally object to the smallest addition to the number of operations involved in the process of obtaining a negative on any substitute for glass. For such persons ordinary plain paper, covered with sensitive gelatine emulsion, answers the purpose, the number of the operations being the same as when glass plates are used. However, prints from such negatives show the grain of the paper, and the printing is very long.

My new sensitive negative paper, which I have patented, is designed to obviate these imperfections, and to render the quality of the print even superior to one obtained from a glass negative. I take the paper and cover it with gelatine emulsion on both sides. When exposing such double-coated paper in the camera, in the first instance, light will act on the front surface next to the lens, then, penetrating the paper, it will act also on the back surface. When this exposed sheet is immersed in the developer, two negatives, one on each side of the paper, will be produced.

But now let us suppose that the paper itself had some spots, both opaque and transparent; these will have no influence on the front image, but the back image will be influenced by the spots, and in the exact ratio of its opacity. In other words, all the imperfections of the paper will be corrected by the back image, rendering the composite negative perfectly smooth, no matter how coarse or imperfect was the texture of the paper employed.

I now pass round for examination a negative produced on this paper bearing some printed matter. The back image had corresponding transparent characters, and very distinct impression of the texture of the paper; but upon looking through the negative all appeared smooth, and such was also the print. Now it will be intelligible that a print from such a negative composed of the two will be also superior as regard roundness and pluck. If the paper used for the purpose be the ordinary photographic paper, Rive or Saxe, the objection to the slow printing remains in full force; but I use instead paper rendered so transparent by a special preparation, that a print from the negative I send round for examination did not occupy more time to print than one from a glass negative of the same density. This special paper offers other advantages. It does not curl when dipped into water, and even after very protracted washing it remains exceptionally strong, bearing an enormous amount of handling without cracking. It appears as if it was not affected by water at all; in fact, if you examine this wetted negative you will observe that to the touch it does not seem at all like paper, but rather like oilcloth or leather.

Now as to the details of using it: In single sheets it can be used in ordinary carriers, provided they are fitted with rebates instead of wire corners. Any rigid plate put behind will press it close to the rebates, holding it perfectly flat. One thing must be taken into consideration. At the back must be a dead black surface (velvet), otherwise, the paper being transparent, reflections from any light object behind will affect the back sensitive surface. However, the most legitimate use of the paper is in the roller slide. The new improved form I will now explain on this model (here Mr. Warnerke showed and explained the new form of his roller slide). The development of this paper is precisely like that of ordinary glass plates, preferably with ferrous oxalate, in order to avoid any pyrogallol stain. After fixing and washing it is advisable to pass the negative through an alum bath, to which has been added a few drops of sulphuric acid. Hydrochloric acid must not be used. This will bleach the paper if it has become discoloured with the iron oxide after long development. The finished negative can be dried on glass previously rubbed with talc, or simply by suspending it; but in this last case it will not be very flat when dry, and it is necessary to damp it again very slightly and to put it between sheets of blotting paper, and submit it to pressure between the pages of a book. After a very short pressing it will come out quite smooth, and will remain so, if kept dry.

# USEFUL AND SCIENTIFIC NOTES.

**High Chimneys.**—The highest chimney in England is said to be that erected in 1839 at Mr. Muspratt's chemical works at Newton. It measures 397ft. 4in. During the same year an immense chimney was completed for the cotton factory of Messrs. Dixon, in Shaddongate, near Carlisle. It is one of the highest buildings in England, being 305ft. from the ground, of octangular form, of brick, with stone angles. The erection was carried on from the inside, stages being erected as the work proceeded, and the workmen and materials being taken up in boxes by a crab worked by four men. The largest structure of this kind in the world is the colossal chimney completed in 1861, by Mr. Duncan M'Farlane, C.E., architect, of Glasgow, for Messrs. Townsend's Chemical Works, Crawford-street, Port Dundas, Glasgow. This great chimney is indeed the loftiest building in the world, excepting the Great Pyramid of Gizeh, the spire of Strasburg Cathedral, and that of St. Stephen's, Vienna. It is circular in plan, and the following are the exact dimensions: Total height from foundation, 468ft.; height above ground, 454ft.; outside diameter at level of foundation, 50ft.; at level of ground, 32ft.; outside diameter at top, 14ft.; thickness at level of ground, seven bricks; thickness at top, 1½ brick. Before the erection of this chimney, that of Messrs. Tennant, Glasgow, was considered the highest known.

**Shrinking in Woollen Goods.**—A German technical journal states that woollen fabrics treated according to the following simple method will be found to be proof against shrinking, and will also retain their colour unchanged. The fabrics are first soaked for several hours in a warm, moderately concentrated solution of soda, to which about half a tumbler of ammonia water has been added, more or less, according to the quantity of material treated. At this stage the fabrics are washed out, after the addition of some water that is warm, then rinsed in fresh water. The same result may be reached by adding a tumbler of ammonia water to a small tub of water, soaking the stuffs for half an hour in this, and finally rinsing them in pure water.

**Spelling of Proper Names.**—The Council of the Royal Geographical Society have issued rules for the spelling of names of places, which are identical with those adopted for the Admiralty charts. The orthography of names in countries using Roman letters will not be affected; all others, only excepting a few familiar names, are to be spelt phonetically, as pronounced on the spot. The vowels are to be sounded as in Italian, the consonants as in English, *ch* being at all times soft and *g* hard, whilst *kh* and *gh* express gutturals. The rules fail to give letters to express the sound of the French *u*, *eu*, or *è*, or of the German *ae*, or *ä*, nor is any attempt made to distinguish between the sound of *ng* in *finger* and *singer*, on the ground that these sounds are rarely employed in the same locality. To this we demur. There may be objections to the introduction of the diacritical signs of Lepsius's standard alphabet, but the desired distinction might be attained either by the introduction of an apostrophe, as in *fin'ger* and *sing'er*, or by writing *fingger* and *singer*. The doubling of the consonants in order to shorten the sound of the preceding vowel is objectionable. The use of the ordinary accents is altogether preferable. Upon the whole, however, the recommendations of the Council are most acceptable, and we trust they will be acted upon not only in the case of maps and geographical works, but also in the case of pronouncing dictionaries.—*Academy.*

**Brockelbank's Weather Shield.**—In Group VI. at the International Inventions Exhibition, Mr. H. Brockelbank exhibits a weather shield and window for Hansom cabs, which deserves notice. This shield is a second roof, and slides forward to form a hood; then it can be lowered partly or completely, making a screen from rain, cold wind, &c., or a closed window. In closing or opening there is no interference with the passenger's head, and the shield can be operated with facility by either the passenger or the driver. An automatic arrangement opens the window, if the horse should fall while it is shut, thus avoiding risk of injury from broken glass.

# SCIENTIFIC SOCIETIES.

## LIVERPOOL ASTRONOMICAL SOCIETY.

THE fourth annual general meeting was held on Saturday, the 25th July; Mr. R. C. Johnson, F.R.A.S. (a vice-president), occupied the chair. The secretary read the minutes of the last annual meeting and a report on the affairs of the society. Since the last annual meeting 87 members and five associates had been elected. There had been one withdrawal, and the society had to deplore the death of the Rev. T. W. Webb, who had been one of its most valued members. There were now 258 members against 166 of last year and 49 of the year before. The fourth session was opened by a paper from Mr. Howard Grubb, F.R.S., F.R.A.S., on "The Adjustment of Equatorial Telescopes." Meetings had been held on the second Monday in each month during the session, at which 98 papers on astronomical subjects had been read and discussed, and the Society had published eight parts of its *Journal* and two numbers of *Transactions*, containing altogether 160 pages of printed matter, illustrated by 42 woodcuts and lithographs. Donations of 186 books and pamphlets had been received, and the publications of the Society had, in turn, been sent to the various astronomical observatories. The total income of the society for the last session had been £72 16s. 6d., and the expenditure £75 4s. 6d. Of the latter sum £69 had been spent in the printing and postage of their publications; the purely local expenses had been restricted to £1 for the rent of apartments. There was also an outstanding account of £23 for printing.

Mr. Isaac Roberts, F.R A.S., F.G.S., said this would leave a deficit of more than £25. He thought the amount for printing was larger than they were warranted in incurring from their present income, and he did not think it would be wise to forestall the income of the approaching session to provide for the deficit. He would suggest in future, either that they should decrease the amount of their literature or that the subscription should be increased, as there could be no doubt they were at present giving more for the money than they could afford to do. The Secretary said this question had been raised before, when it was decided that to increase the subscription would be to take the Society out of reach of the very class it was intended to encourage. As to the supposed deficit, he thought it would turn out rather a profitable investment when the assets were taken into consideration, for though they could not well be placed on the credit side of the balance sheet, he had no doubt that when they came to be realised there would be a considerable balance in their favour. The demand for the Society's publications had hitherto been very great, and even increased prices had been offered for numbers which were out of print. Last session such an emergency had been provided for by printing a larger supply, which had, of course, increased their expenses without in the mean time bringing in any return. The work of the Society had been very extended, and it had been thought preferable to increase their sphere of usefulness rather than to lay up a reserve fund; though, even looked upon as a commercial speculation, he would have every confidence in their success.

Mr. W. S. Franks, F.R.A.S., noticed with regret that Mr. Espin was obliged to remove from Liverpool, and would therefore be unable to undertake the duties of special observer. The fact, however, that he had purchased one of Calver's 17in. reflectors looked hopeful, and, whether special or not, he was sure Mr. Espin would continue one of their most valuable observers. (Applause.) The president and officers for the ensuing year were then balloted for and declared elected as follows:—President: Isaac Roberts, F.R.A.S., F.G.S. Vice-presidents: Rev. T. E. Espin, B.A., F.R.A.S.; W. H. St. Q Gage, F.R.A.S.; R. C. Johnson, F.R.A.S.; Rev. S. J. Perry, F.R.S., F.R.A.S. Special Observer: W. H. St. Q. Gage. Treasurer: G. C. Beecham. Secretary: J. W. Appleton, F.R A.S. Editor of the Society's Publications: W. H. Davies, F.R.A.S. Council: Joseph Baxendell, F.R.S., F.R A.S.; Miss E. Brown; W. F. Denning, F.R.A.S.; W. H. Davies, jun.; Thomas Gwyn Elger, F.R.A.S.; W. S. Franks, F.R.A.S.; J. E. Gore, F.R.A.S., M.R.I.A.; Rev. J. H. Honeyburne, M.A., F.R.A.S.; George Knott, LL B., F.R.A.S.; R. S. Newall, F.R.A.S.; W. H. Sharp, H. Thomas. Messrs. G. R. Farncombe, B.A., F. W. Longbottom, J. Scaife, and W. H. Wesley (R.A.S.) were elected members of the Society.

**Red Staining for Wood.**—The wood is plunged first in a solution of 1oz. of curd soap in 35 fluid ounces of water, or else is rubbed with the solution; then magenta is applied in a state of sufficient dilution to bring out the tone required. All aniline colours behave very well on wood.

# SCIENTIFIC NEWS.

THE comet discovered by Mr. Barnard on July 7 has been observed at Kiel, Arcetri, Vienna, Strasburg, Rome, and Palermo. Dr. Holetschek, of Vienna, computes that the perihelion passage will be the 25th of September, when the comet will have so far increased its distance as to become too faint almost to observe. Its present distance is about 150 million miles; but the comet is not of much interest. Prof. Millosevich, of Rome, says that it has a nucleus of about 11m. in the preceding part of the nebulosity. According to Mr. Chandler's calculation the perihelion passage was in May, but it seems probable that it will not occur until September.

Tuttle's comet should be looked for next month in the north-east, in the early hours a.m., though it is not expected until September.

Small planet 248, discovered by Dr. J. Palisa, of Vienna, has been named Lameia.

The Astronomische Gesellschaft meets at Geneva on August 19, Prof. Auwers presiding. Dr. B. A. Gould has presented the society with the stereotype plates of the catalogue formed from the Cordoba zones, and they will be preserved at Leipsic.

The fourteenth meeting of the French Association for the Advancement of Science will take place on August 12, at Grenoble, under the presidency of M. Verneuil, member of the Academy of Medicine. The public lectures will be on "The New Gallery of Palæontology in the Paris Museum," by M. Cotteau, and on "The Victualling of France," by M. Rochard. Numerous excursions will take place in the Alps as far as Chambery.

Mr. G. H. Darwin is making progress with the biography of his father. The volume, it is stated, will contain an interesting account of Darwin's method of research, and for the first time the public will have presented to them a true picture of the great naturalist's home and daily life. It is anticipated that the book will be issued before the year is out.

Mr. Alexander Watt is finishing a practical treatise on the electro-deposition of metals, including the electrolytic refining of copper and other metals and treatment of ores. The work will shortly be published by Messrs. Crosby Lockwood and Co.

The half-yearly meeting of the Scottish Meteorological Society was held on Monday in Edinburgh, Mr. J. Murray in the chair. Mr. Buchan submitted the report of the council, which stated that the cost of maintaining the observatory on Ben Nevis had been £335 above the amount of subscriptions received, and that £800 would be required to carry it on during the next twelvemonth. A temporary branch of the marine station had been established at Millport, on the Clyde, and much good work had already been done there. It was hoped that it might soon be possible to establish a permanent station on the Clyde. Dr. Sanderson gave in the financial report, from which it appeared that the memberships now number 689, and that the income for the year ending June 30th last amounted to £456, of which £417 was received in subscriptions. A sum of £5,154 had been expended in connection with the Ben Nevis Observatory, of which £2,020 was for building the observatory, and £1,798 for making the road to the top of the hill. The income of the marine station at Granton amounted to £998, and there was now a balance at its credit of £641. Professor Ewing, Dundee, gave an account of a scheme for the observation of earthquakes which it is proposed to carry out on Ben Nevis. He said that to find the earth in perfect stillness was extremely rare, and he supposed that what was meant to be investigated was every description of earth movements.

The Marine Biological Association is to receive Government aid on condition that its work is carried on in full concert with the Scotch Fishery Board. Our fisheries have been too long neglected, and it is satisfactory to find that at last the Government are aware of their national importance.

A useful course of lectures was concluded last week at the Birmingham and Midland Institute, when Mr. C. T. Millis, of the Technical College, Finsbury, delivered the last of the series on "Pattern-cutting for Sheet-metal Workers." Mr. Millis commenced his course by showing that pattern-cutting or, more strictly speaking, the development of surfaces, was the laying out of the surfaces of solids in a plane, and then dividing the articles for which patterns were required by sheet-metal workers into three classes, the first articles having equal slant or taper, such as coffeepots; the second articles having unequal slant or taper, as baths, hoppers, canister tops, &c.; and the third bent or twisted surfaces, such as vases, aquarium stands, moulding, &c. He then proceeded to explain the application of solid geometry to the setting out of the foregoing patterns, and the general principles underlying the same, methods for setting out patterns in a round, oval, and oblong, and for other articles of equal and unequal taper, such as elbows, T-elbows, elbows formed by tapering pieces of pipe, &c. Copies of supplementary notes, containing definitions for geometrical problems, useful to sheet-metal workers, were prepared by Mr. Millis and distributed to those attending the lectures—from 150 to 200 working men, the tickets of admission being distributed by the representatives of the societies of tin-plate workers, braziers, ironworkers, and similar bodies. It is proposed to bring before the Birmingham Trades Council a proposition to establish a class during the next session of the institute to carry on the work.

Bull's patent process of steel manufacture by means of water-gas—converting ore into steel without first making pig—is being tried at Trimsaran, Kidwelly. The following description of the process is published:—The gas producers are similar to the Strong and Lowe, or the *quasi* recuperative type. The coal is forced by a hot blast of air into partial combustion, the resultant heat of which is collected into separate recuperators. An interval follows, during which the air is turned off, steam is forced in a reverse direction through the recuperators, and becoming highly superheated, is decomposed or transformed into a powerful reducing gas. This is led through conduits to the tuyères of the blast furnace. It is expected from the careful arrangement of the crucible of the blast furnace, which is of the cupola form, that a bath of pure iron can be maintained in a fluid condition. When the metal is tapped it will be carried by ladle, and run into a Siemens open-hearth steel furnace.

At a recent meeting of the Master Car Builders' Association of the United States, the question of automatic couplers for goods waggons came up for discussion. Notwithstanding the Massachussetts law and the Boston trials, the difficulty of introducing a uniform automatic coupler is so great that only slow progress is being made. The Legislature of New York State has passed a law which declares that after July 1, 1886, couplers on new freight cars must be capable of being worked automatically. The subject was referred to the Executive Committee, to make a public trial, to employ experts, and to request the co-operation of the railroad companies.

Dr. Ramos, of Bristol, says that refrigeration of the lobe of the ear will stop hiccough. The refrigeration need be nothing more than the application of cold water.

Dr. G. W. Jacoby, of New York, read a paper recently before the American Neurological Society, in which he stated that hypodermic injections of a one per cent. aqueous solution of osmic acid had been found an effective remedy in the treatment of peripheral neuralgia, especially in the case of sciatica.

At the meeting of the San Francisco Microscopical Society, on June 24th, Mr. W. Norris presented a set of nineteen slides, being the first instalment of a series, which is intended to be a complete collection of all known Californian diatoms. Dr. J. H. Stallard read a paper on "Pathogenic Bacilli," in the course of which he stated that Koch's views as regards the cholera bacillus will soon be, in all probability, established beyond reasonable doubt.

Mr. A. Lyman, of New York, has invented a new cartridge, which consists in packing the shell with meal powder, and leaving a longitudinal hole quite through. It is contended that by this arrangement the ignition begins within the walls of the perforation, and gradually extends, the charge burning with augmenting rapidity, and the gas pressure rising steadily, so that the full effect is expended upon the projectile. From a smooth bore $\frac{6}{16}$in. calibre, 4ft.

long, a projectile 9in. long, weighing 3½oz., has been driven into a target composed of nine plates of ¼in. boiler iron, with a powder charge of less than an ounce. The inventor thinks that a 3in. gun and 40lb. of powder will send a projectile through a solid iron plate 3ft. thick.

According to Herr Stutzer, writing in the *Zeitschrift der Physiologische Chemie*, all vegetables contain three groups of nitrogenous substances—one soluble in water, represented by asparagine; the second, comprising albumen, dissolved by the hydrochloric acid pepsin of the stomach, and chemically distinguished from amides by forming insoluble compounds with copper hydroxide in neutral solutions; the third, composed of all those nitrogenous substances which are not soluble in water or in acid pepsin. The last group was the one examined. Commercial cocoanut cake used as fodder by farmers was treated with pepsin and pancreatic extracts, and it was found that the latter in an alkaline solution had somewhat less action on proteids than acid pepsin. The author's observations lead him to believe that soda alone is quite as powerful a solvent of nitrogenous principles as when combined with pancreatic ferment.

We learn that Mr. Clement L. Wragge, F.R.G.S., late of Ben Nevis Observatory, in consequence of recent correspondence, intends to visit Brisbane shortly. His mission is to confer with Major-General Scratchley, K.C.M.G., and the Queensland Government on matters relating to meteorological work in Northern Queensland and New Guinea. He hopes to establish a station at Port Moresby. An assistant will carry on the work of his Torrens Observatory, near Adelaide, aided by self-recording and electrically-registering instruments, and the result will henceforth be sent direct to the Royal Meteorological Society and the Government Meteorological Office, London, with both of which the Torrens Observatory is connected. Mr. Wragge is also arranging for the continuance of his observatory on Mount Lofty, South Australia.

**Artificial White Light with Metallic Magnesium.**—Magnesium added to a pyrotechnic mixture brightens the brilliancy of its flame amazingly. The powdered metal, as manufactured by the electrolytic process, can be well used for that purpose. Two and a half per cent. magnesium added gives the red strontium light a wonderful brightness, while with the barium light its green colour is rendered perfectly white, resembling the electric light. Such mixtures might serve well for photographic purposes; if with properly constructed apparatus and chimneys, the troublesome smoke and the evolution of injurious gases may be got rid of. The manufacturers of magnesium by electrolysis recommend for white light, one part shellac to be fused together with six parts of barium nitrate, the mass to be reduced to a fine powder, and thoroughly mixed with two and a half per cent. magnesium. For red lights the same amount of magnesium with one part of shellac and five parts of strontium nitrate answers well. When being used the mixture is spread upon a piece of sheet iron and ignited, or it is placed loosely in tubes of very thin sheet zinc of about two c.m. diameter. As the combustion proceeds the zinc is consumed with the pyrotechnic resistance.

**To Colour Brass Steel-Grey or Black.**—Add one part of hyposulphate of soda and two parts of sulphate of copper to 100 parts of water. Cleanse thoroughly the object to be coloured, place it in the mixture and heat it. A darker tint is procured by adding more hyposulphate of soda, while a larger quantity of sulphate of copper will produce a bluish or steel-grey colour.

M. de Tromelin has attacked the hypothesis that clouds are composed of vesicles or hollow spheres of condensed vapour. He supposes that every solid body, whatever may be its diameter, retains around it by adhesion a special atmosphere of the gas in which it is plunged; that the thickness of this atmosphere is nearly independent of the volume of the solid body; that the attraction which retains it is within the domain of the molecular forces, and is manifested only within very short distances. In this way he accounts for the difficulty of completely removing the air from a tube which is to be filled with liquid. In the case of a vesicle surrounded by its atmosphere, the thermal absorption of the water is much greater than that of the surrounding diathermanous air. The atmosphere of the vesicle is consequently expanded, and the particle with its atmosphere floats by displacing an equal volume of the circumambient air. The dust particles which are observed in the sun's rays are supposed to be sustained in the same way.

# LETTERS TO THE EDITOR.

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original."
*Montaigne's Essays.*

## THE PRIME MERIDIAN FROM A FRENCH POINT OF VIEW—ANOTHER PRICK OR TWO FOR THE SUN-SPOT BUBBLE—TERRESTRIAL TELESCOPES—THE POWERS THAT (CAN'T) BE—TARDY "NOTICES" OF PHENOMENA—EQUATORIAL MOTION FROM AN ALTAZIMUTH ONE—SPECTROSCOPE.

[24537.]—I have been highly amused by the perusal of the report of a lecture by Dr. Janssen on "The Universal Prime Meridian," delivered before the Paris Geographical Society. As an example of Spread-cock-yism (if I may adapt a familiar American expression) it is perfect. The learned Doctor is most irate that so overwhelming a majority of the delegates to the Washington Conference should have selected Greenwich as the initial point for all terrestrial longitudes. Richelieu settled the Meridian, and it seems a kind of horrifying piece of impertinence to Dr. Janssen that anyone should dare to upset what was decreed by the notorious Cardinal, in joy at whose death bonfires blazed all over Paris. Il va sans dire that France has effected practically everything that has been done in geography and hydrography, whence the ingratitude as well as the folly of the selection made by the Congress becomes apparent at once. One infinitesimal crumb of comfort the French delegate does seem to have picked up at Washington—General Strachey announced that England has begged to join the Metric Convention. Just so, England (or the tailors of Tooley-street who claim to speak for her) may join the Convention; but if General Strachey does not die until the most unscientific French system, founded on an erroneous measure of a local Meridian, is used in English commerce—well, Methuselah will be a baby to him!

Humbug dies hard, and I do not, therefore, apologise for once more reverting to the subject of sunspots and the weather. All readers of the English Mechanic must know how blatantly it has been asserted that the years of maximum Solar disturbance are those of the greatest rainfall, and *vice-versâ*, such assertion having been made in this country as a reason or excuse for demanding that someone should be installed in a "Solar Physical Observatory," at a large salary, in order that, by watching sunspots, he might predict the weather. In letter 24196 (p. 211), I made extracts from the Report of the Committee on Water Supply presented to the Meteorological Society, and since then I have been reading the "Report of the Astronomer Royal to the Board of Visitors of the Royal Observatory, Greenwich, Read., 1885, June 6th," in which I find Mr. Christie stating on p. 10 that "it would seem that the maximum both of sunspots and faculæ occurred about the end of 1883 or beginning of 1884"; and on p. 14, "The rainfall in 1884 was 18·0in., being about 7 inches below the average of the last 40 years." The same condition of things is recorded in the Meteorological Observations made at Stonyhurst, where the rainfall last year was 5·47in. below the average of the previous 37 years—and so from all parts of the kingdom. Recently, too, I have come across a very interesting work entitled "Observations Upon the Topography and Climate of Crowborough Hill, Sussex," by C. Leeson Prince, M.R.C.S., F.R.A.S., &c., which contains, amid a quantity of other information, elaborate details of Sussex Rainfall for 46 consecutive years. Taking the pains to compare this with Wolf's Tables of Sunspot Maxima and Minima, I find that not the smallest discoverable connection exists (or has existed for 46 years, at any rate) between the spotted area of the sun and the amount of rainfall. Now, this is a question of *fact*, and not of the very least of opinion, which is open to investigation by everybody who can read and write; and in the teeth of it, it is impossible not to question either the bona fides or the absolute sanity of any person or persons persisting in attempting to blow the pricked bladder up again.

Might I be allowed to suggest that the reproduction in these columns of the article by Professor Holden (to which Mr. Sadler refers in the concluding paragraph of letter 24474, p. 428) would be of interest and advantage to a great many of your readers who cannot obtain access to the publication in which it originally appeared.

Premising that Kitchiner was far from being the most careful writer who ever lived, I rather fancy that the solution of Mr. Mee's difficulty (letter 24477, p. 428), or part of it, will be found in the fact of the untrustworthiness of the estimation of the powers of eyepieces made by the opticians who construct—or sell—them. A few (a very few) of the highest class will measure such powers accurately, and furnish the purchaser with the true amount of amplification; but when one gets to high powers and the run of telescope sellers, the tendency to exaggerate seems irresistible. Besides, while, of course, a power of 2,000 on a 7in. reflector would show a bright star as an amorphous smudge of light, no observer could legitimately say that he had *seen* the star with any such a power. Finally, note what Kitchiner himself says in various parts of his book "On Telescopes," as to the use—or rather, utter uselessness—of high magnifying powers (p. 74).

Letter 24504 (p. 451) suggests to me to say that on the morning of July 22nd I received the June number of the R.A.S. *Monthly Notices* containing Dr. Hind's predicted details of the occultation of Aldebaran, which had happened 13 days previously! Of the value of this to those Fellows of the Society who happen to be practical observers it would be needless to insist. Happily in the English Mechanic we have a journal read practically by every owner of a telescope in the United Kingdom. If we were left to the tender mercies of Burlington House for the announcement of such phenomena as a daylight occultation, I am a little afraid that many a one would go unobserved and unrecorded.

The task set by "Montmartre" in letter 24508 (p. 452) is beyond my capacity, inasmuch as the quantities of altitude and azimuth and hour angle and N.P.D. do not vary equably, which they must do if an equatorial motion could be obtained by a single movement. *A fortiori* this would apply to an arrangement for following the moon with her very irregular motion. For example, she souths to-morrow morning 45 minutes later than she did this; on the morning of August 7 one hour later than on that of the 6th; on the morning of Sept. 1 52 minutes later than she did on that of August 31, and so on.

It is quite worth the while of "E. B. F." (query 57100, p. 463) to attach a 5-prism spectroscope to any astronomical telescope of an aperture exceeding 3in. With it he would see the C, $D_3$, and F lines bright in the spectra of the solar prominences. He had better buy Browning's "How to Work with the Spectroscope," for a reply to his succeeding query (57101).

**A Fellow of the Royal Astronomical Society.**

## ASTRONOMICAL.

[24538.]—I have no wish to appear to dispute with so eminent an astronomer as Mr. Franks (letter 24505), so, if you will allow me, I will only ask him to think over and compare his own dicta as to 100 to the inch and the explanations I offered. The "reductio ad absurdum" is founded on his statements, not on mine.

May I be allowed to ask him if all vision is not identically the same, whether of stars, planets, or the page of "E. M." on which this appears? Every image is made up of points, and the light from any point passing through any aperture results in a disc and diffraction rings. In practice only bright points make sufficient impression on the retina to produce rings, and in the case of surfaces the discs and rings overlap and become continuous. This is optical theory. Perhaps Mr. Franks denies it.

But he tells us "the intrinsic brightness of either a bright star or faint *comes* depends upon aperture and nothing else." Will he kindly consider this again? The total amount of light from a star depends upon the aperture; but when we raise a disc and spread that light over a perceptible area, we certainly, in my judgment, reduce the intrinsic brightness. We see the faint *comes* as well under such circumstances, because the same quantity of light reaches the retina, but the image is less bright. I am afraid this is a "reductio" again.

If Mr. Franks still differs, I can only ask him to try it practically, premising that if his aperture will not stand 100 to the inch and give clean discs, it is necessary, in order to try fairly, to reduce aperture to some size that will do so. If he does not find star images decrease in intrinsic brilliancy as they increase in size with powers above 50 to the inch, I will admit I fell into the ditch he speaks of.

I have read "Newcomb" with attention, but I certainly gain by using high powers on close objects; and I think a perusal of Mr. Sadler's letter

(24352) shows great observers have been of opinions very similar, and have found the same practical results. Messrs. Franks, Gaudibert, and some others appear to possess exceptional sight, which enables them to see close doubles and elongations with low powers. I have no such ability.

In letter 24478, *re* 70 Oph., does ang. lat. 40° mean P A 40°? Because if it does, I must, with all due deference, ask Mr. Franks to measure again.

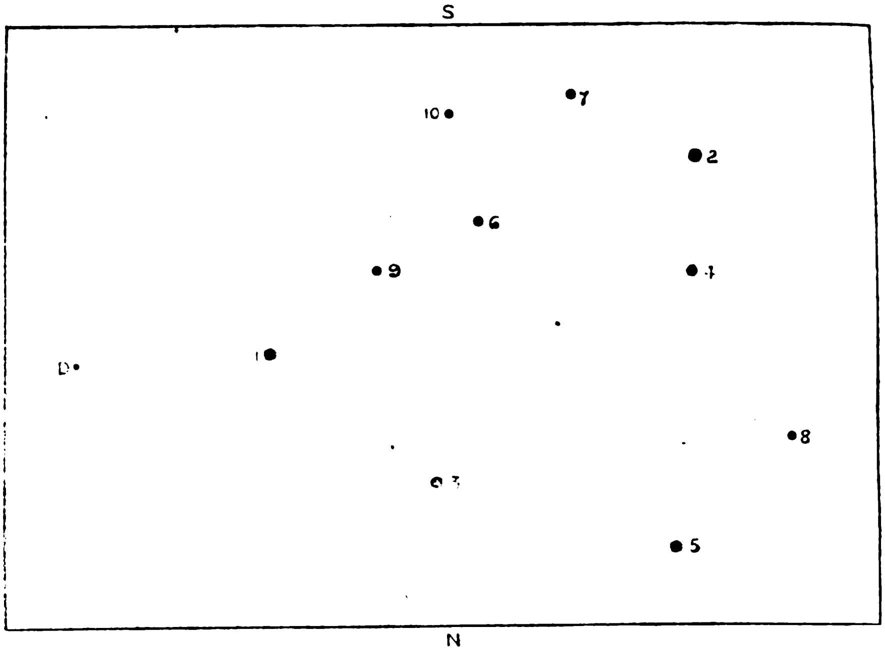
I believe the *comes* to 101 Cassiopeiæ is seldom seen. It may interest some to know that on July 8th I saw it north and a little preceding. The best est. of position is that it is in a direct line for the preceding star of the 10·3″ pair.

What is present distance of close pair of Σ 2481?

Webb mentions two faint *comes* to 6468 B A C. This should be three, as there is another at same distance as the two.

Mr. Tarrant furnished me with sketch of 53 Ophiuchi, and I have seen all his stars; but I am sure there are more within the space he includes, although the thick London air will not allow me to see them well enough to fix their positions. He shows one, a little *p.* a line from C to D. There is another star between this and C.

**E. Holmes.**



## THE RED STAR BIRM. 464.

[24539.]—THERE is an error of about half a minute in the R.A. of Birm. 464 in Schj.'s first catalogue of red stars (*Ast. Nach.* 1591), which Mr. Birmingham has followed in his Red Star Catalogue, and in his reference to this star in the *Monthly Notices* for June 1874. Schj.'s place in his second catalogue is correct. I have only been able to find two indubitable meridian observations of it, after searching more than 100 catalogues; for the supposed determinations in the Dunsink Observations iv. cannot belong to this star. It was also observed once in a 20ft. sweep by Sir J. Herschel. The following are all the results known to me, reduced to 1880·0:

| | h. m. s. | |
|---|---|---|
| $H_2$ | xviii. 43 48·47 | − 8° 2′ 26 4″ |
| Santini | 49 49 | 33·5 |
| Lamont | 49·20 | 39·1 |
| [Dunsink | 24·73 | 24 6] |

$H_2$'s observation is given in his list of red stars on page 449 of the "Results of Astronomical Observations made at the Cape of Good Hope." It was made in a sweep in the last half of the year 1827. Santini's observation is found in the zones at the end of his little-known work, the "Descrizione del Circolo Meridiano dell' I.R. Osser. di Padova"; the observation was made in July 1844, and is the mean of two determinations. The three observations on which Lamont's result is founded were made in September 1860, August 1861, and September 1863. They are given in the "Annalen der König Sternwarte bei München (Supplement-Band ix.)" The Dunsink place is the mean of two determinations (one being allowed only ⅓ weight) by Dr. Dreyer in 1879 and 1880. I have marked this "D" in the diagram. The magnitude is given as 9·5 on July 29th, 1880, the best observation; but Burnham called Birm. 464 7 0 mag. on July 24th, and 6·8 mag. on July 31st, 1880. The object observed at Dunsink is evidently some other star near. It is curious that, though Birm. 464 appears as the brightest star of the triangle on the maps of Inghirami and Capocci, its place was not determined by the former, though he observed Nos. 2, 4, and 5 (the numbers are those given by Mr. Gemmill in letter 24480, page 429). Its absence from Bessel may be accounted for either on the supposition that the star was so faint at the time the zone was observed at Königsberg as to escape Bessel, or, which I think more probable, that the star being a bright one, Bessel preferred to observe the fainter star No. 5 near it, leaving the bright one for other observers. There is possibly a third explanation. Birm. 464 has a very faint *comes* at 14·3″, forming the pair β 969, and No. 6 appears to be β 970; while No. 9 is apparently *h* 868, given in Sir John's third catalogue without mags., pos., or distance, as "a beautiful little double star in the field with a most remarkably red star 9 mag." It is from this observation that the star is included in the list of red ones in the Cape observations. It would seem at first sight as if Birm. 464 had a considerable p.m. in decl. from a comparison of the observations of $H_2$, Santini, and Lamont; but $H_2$'s observation is not of course delicate enough to determine this, and Santini's is in error, as there is a similar discrepancy between his observations of No. 5 and Lamont's, while Bessel's place of No. 5 agrees exactly with the latter's, as does Santini's No. 2. In the diagram I have inserted Nos. 1, 2, 3, 4, 5 from Lamont, 6 from Burnham, 9 from Herschel, 7, 8, and 10, from Inghirami's map ("Mappa Uranographica," also in the Berlin star maps). This map was made in 1827 and 1828, and Capocci's about the same time. Inghirami used a 4in. Fraunhofer, and annular micrometer, Capocci probably a 3⅓in. I regret that owing to its south declination I am not able to examine the group. The following are the mags. of Birm. 464, not included in his Red Star Catalogue (with the exception of Herschel's), with the dates—

Herschel. 1827·7 9 mag., "most remarkably red."
Inghirami. 1827-1828 8 mag. Estimated from map.
Capocci. 1828 ± 8 mag. Estimated from map.
Santini. 1844·52 7 mag. Colour not noted.
Lamont. 1860·73; 1861·63; 1863·74. 6½ mag. Colour not noted.
Burnham. 1880·53, ·54, ·56, 7·0 mag.; 1880·58 6 8 mag.
Gore. 1884·71 8 mag.
Gemmill. 1884·63 8 mag. "Magnificent ruby."

I do not think that, all things considered, there is much evidence of variation. The mags. assigned to red stars by different observers vary considerably. For instance, Mr. Webb made the magnitude of this very star 9·5 on Sept. 22nd, and Mr. Birmingham 7·5 on Sept. 23rd, 1873.

The following are the magnitudes assigned to the other stars in the group, including those which I have estimated from the maps of Inghirami and Capocci.

| No. | Ll. | Bessel. | Ing. | Capocci. | Santini. | Lamont. | Burnham. |
|---|---|---|---|---|---|---|---|
| 2 | 8½ | | 8½ | 8 | 8 | 7 | |
| 3 | | | 9 | 8½ | | 8 | |
| 4 | 8 | | 8 | 8 | | 7½ | |
| 5 | | 8½ | 8½ | 8 | 8½ | 7 | |
| 6 | | | 9 | 9 | | | 8 3 |
| 7 | | | 9 | 9 | | | |
| 8 | | | 9 | 9 | | | |
| 9 | | | | | | | |
| 10 | | | 9½ | | | | |

July 24th. **H. Sadler.**

P.S.—Burton's mag. (7·5) of Birm. 607 does not appear in the Dublin observations.

## THE DAYLIGHT OCCULTATION OF ALDEBARAN.

[24540.]—REFERRING to Mr. Pearson's remarks on the above subject which appeared in your issue of the 24th inst., I would beg to inform that gentleman that the times of immersion and emersion were taken at Rousdon by a sidereal chronometer which has been rated by star transits taken at my observatory with an instrument in excellent adjustment, and I have, therefore, no doubt whatever that my time is correct within the decimal of a second, and is quite independent of the position of Lyme Regis.

As Mr. Pearson is doubtless aware, there is considerable difficulty in deciding upon the exact instant of emersion in the circumstances under which the occultation of Aldebaran took place (the full blaze of sunlight), and, therefore, a small error may possibly occur in the time noted; but with the immersion the case is entirely different, and the time of that phenomenon is accurately given, in proof of which I may mention that the longitude deduced from it agrees exactly with the position of Rousdon Observatory, derived from a recent measurement taken by the Ordnance Survey Department.

I am unacquainted with Mr. Pearson's partially graphic method, beyond casually glancing at some examples of it given in the ENGLISH MECHANIC. It, however, appears to be a modification of the well-known graphic method of Mr. Penrose.

While thanking Mr. Pearson for his kind advice, I prefer to trust to the results of actual observation, and time derived from transits, rather than to his method which, at the best, can only give approximate results. **C. E. Peek, M.A. F.R.A.S.**

Rousdon Observatory, July 27th.

## THE DOUBLE STAR Σ. 1959—ERRATUM.

[24541.]—I AM glad that Mr. Gaudibert (letter 24503, p. 451) has succeeded in identifying his pair. I mentioned Σ. 1959 because the angle and distance seemed similar to those of Mr. Gaudibert's pair, though as Σ. 1959 was included in β.'s first series of Chicago measures (which I thought Mr. Gaudibert possessed), and the magnitudes were so very different, I hardly thought it possible that the two could be identical; still, I was surprised that so bright and easy a pair, as Mr. Gaudibert's seemed to be from his description, should have escaped notice so long. Σ. 1959 is either W. B. (2) XV. 668 or 670; but I do not know which of the two it is, as it is not in *Pos. Med.* β. identifies it with 668, and Stone with 670. The places for 1885·0, brought up from Weisse's Bessel, are—

W. B. (2) XV. 668. XVh. 30m. 9·1s. + 35° 9′ 8 9″
670. XVh. 30m. 16·1s. + 35° 6′ 27·9″

Bessel calls both 9 magnitude; Arg. rates 668 at 9·1 mag., and 670 at 9·0. Σ. calls A of his 1959 9 mag. in 1829, and 8·5 in 1831 and 1833. It has very seldom been measured, though De. observed it five times between 1863 and 1872, calling the larger star 9·5 mag. in Σ.'s scale on all five occasions, B ranging from 10·0 to 11·0 mag., or 10·4 mag. as a mean. De. calls it very difficult on three nights, from its faintness and comparative closeness. Howe rated A 9 0 and B 10 0 mag. on the one evening on which it was measured at Cincinnati. The difference between these estimates and Mr. Gaudibert's is astonishing. The following are the principal measures:—

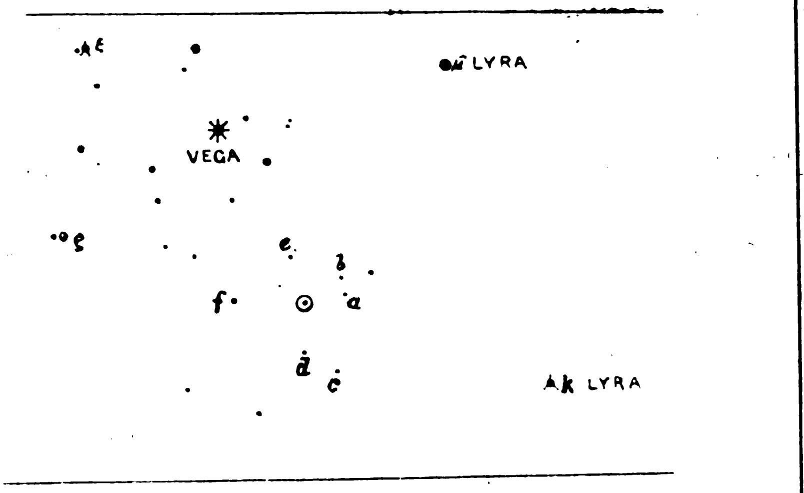
| | | | | | Mags. |
|---|---|---|---|---|---|
| Σ. | 241°·07 : | 1″·713 : | 1831·58. | 3 nights. | 8·7, 10·3 |
| De. | 240·86 : | 2·002 : | 1868·27. | 5 nights. | 9·5, 10·4 |
| β. | 242·3 : | 2·08 : | 1878·41. | 1 night. | not given |
| C. O. | 240·1 : | 1·80 : | 1879·30. | 1 night. | 9·0, 10·0 |

The pair is evidently unchanged. As 8·5 Σ. is about equal to 9·1 mag. Arg., the agreement of the various estimations of magnitude is satisfactory; but this makes it the more remarkable that Mr. Gaudibert should ever have called A a 6th magnitude star. I should be glad if he would look again at this object, and determine which of the two stars in Weisse's Bessel Σ. 1959 is. His circles, by the way, must be considerably out of adjustment. It is curious that the place of Bode 26 Coronæ should have agreed so exactly with Mr. Gaudibert's first place for his pair.

In letter 24532, page 456, *for* 13·9in. Henry Bros. *read* 14·9in. Henry Bros. **H. Sadler.**

## B. 448 VEGA.

[24542.]—IN reply to Mr. Gemmill's request (letter 24480), I send the accompanying little map of the vicinity of B 448 copied from Harding's Atlas, which will, I hope, help him (rough though it is) to find Birmingham's star. The position of the red star (which is not given by Harding or Lalande), marked by a small circle, I have laid down carefully from Birmingham's position reduced to the epoch of Harding's Atlas (1800). I



have lettered the small stars in its immediate vicinity, and they are as follows :—

*a* = Lalande 34324 (8½m.)
*b* = „ 34335 (8)
*c* = „ 34342 (8)
*d* = „ 34421 (8)
*e* = „ 34412 (7½)
*f* = „ 34570 (·)

There is no magnitude assigned to *f* in Lalande's catalogue; but the star was estimated 7½m. by Hencke (*Mon. Not. R.A.S.*, 1859, *p.* 341).

With reference to B. 607, my only authority for Burton's 7·5m. is the note in the "Red Star Catalogue." Burton's estimate certainly seems very small. If B. 607 is really variable, the limits of variation would, I think, be included between 4m. and 6m.

With reference to the obsevrations of "H. D." (letter 24479), I may say that the distant *comes* to Vega *is* a suspected variable, and is No. 556 of my Catalogue. **J. E. Gore.**

July 18.

## TWO BRILLIANT METEORS—BARNARD'S NEW COMET.

[24543.]—While engaged in comet-seeking with the 9in. reflector on the evening of July 6th, about eleven o'clock, I was startled by an almost blinding flash of light in the telescope. Quickly removing my eye from the instrument and looking upwards, I beheld a magnificent meteor moving rapidly from a point south-east of the zenith towards the north-west. It disappeared at an altitude of about 40°. Before disappearing it burst into four or five balls of varied colours, those in the rear being a vivid green merging into purplish, the foremost and largest ball being an intense crimson. No report was heard, although listened for some time. No visible train. I learned the next day that it had been seen in other places, one of them forty miles west of this observatory.

Again, on the morning of July 8th, while resting my eyes momentarily from the telescope, I saw another very fine meteor moving across the northern heavens from east to west below Polaris. This one left a very bright train visible to the naked eye two or three minutes, and in the telescope which was turned upon it (as is my custom often) it could be seen for a much longer interval twirling and curling into most fantastic forms.

The new comet discovered July 7th by our good and industrious fellow-worker, E. E. Barnard, of the Vanderbilt University, Nashville, was readily picked up by me on the evening of July 10th, in approximate R.A. 17 hours, 15 minutes; declination south 6° 30′. It is faint, and has a peculiar flashing appearance in different parts of the coma. It has a good-size nucleus decidedly on one side, and that, naturally, towards the sun. Last night I saw indications of a very short brush-like tail. The comet was easily found with the 9in. Newtonian, and was seen afterwards with the aperture reduced to 4in. **William R. Brooks.**

Red House Observatory, Phelps, N.Y., July 13.

## THE GIME ACCUMULATOR.

[24544.]—Have any of your readers had any experience with the Gimé accumulator, which is thus described in a French paper:—The new accumulator of M. Gimé is composed of cylindrical tubes of lead, placed vertically in the following position:
o o
o in an oaken chest, lightly coated with gutta-
o o
percha, and forming a series of lines analogous to and in much the same manner as the plates of other accumulators. All the tubes of the same line communicate with each other, the alternate lines being joined to the negative and positive poles of the battery. The tubes are filled with sulphate of lead, which the inventor has found to be preferable to red lead, and perforated with vertical apertures, which permit the liquid to enter and rise to the top. The combination of elements does not differ essentially from that found in the ordinary type of accumulator. But the construction of the battery is unique, and possesses this advantage: the leaden cylinders, when in use, can be far more readily removed than the plates of other accumulators. From the information given by M. Gimé of the work of an element of 100 kilogrammes—the only type yet constructed—the formation of the element lasts 120 hours. It returns in the discharge 85 per cent. of the energy absorbed during the charge. Its practical capacity is 3,700 kilogrammètres per kilogramme of lead, and its electromotive force at the discharge is more than three volts—sometimes as high as 3·5 volts. We give these figures as they have been given to us, and without vouching for their accuracy. The last assertion, above all—viz., as to the E.M.F.—is especially doubtful, and should assuredly be taken *cum grano salis*. For the chemical action produced by the element, Gimé would seem to be almost identical with that observed in the Platé secondary battery, as well as in the Faure-Sellon-Volckmar type, and, so far as we can see, there is nothing in the construction or working of the Gimé battery that explains how such an E.M.F. as that claimed by the inventor could be generated. Nevertheless, the new apparatus shows great ingenuity in its construction, for it is simple, and permits of the easy and expeditious removal of the positive leads, which, if the battery possesses the economical qualities attributed to it by its inventor, will serve to make it particularly valuable in industrial employment.

As I wish to construct a large accumulator battery for experimental purposes, I should be glad to have the criticisms of your readers, Mr. Sprague and others, on this form. **G. M. B.**

## 100 TO THE INCH APERTURE.

[24545.]—I have been a devotee to telescopic pursuits all my life, and have derived no small amount of information from the pages of the "E. M." I would not trouble you now, but some of the remarks of our friend and mentor, Mr. W. S. Franks upon the 100 to the inch question seem to need further explanation.

He says (letter 24505) that he must maintain "that the atmosphere does enter into this question," the question being whether the atmosphere can set optical theories at defiance, and so prove that a 26in. telescope could not bear 1,300 on planets. Is there any reason why, given a sufficiently steady night, a 26in. should not bear 1,300 as well as a 12in. will bear 600. If there is not, then the question is not a question of comparative powers different-sized instruments will bear, but of the limit our atmosphere practically imposes on the highest powers possible on any telescope. Atmospheric disturbance may limit the highest power possible to one that can be well enough used on a 10in. instrument; but this is not setting optical theories at defiance.

If a 26in. on sufficiently steady air will not stand as high a power as a smaller instrument proportionately, can Mr. Franks give us any reason for its failure, supposing it to be perfect in figure? And I cannot follow him as to brightness of star images. If, as he says, it is dependent upon nothing else but aperture, then I suppose he means that the intrinsic brilliancy is the same whether I use 100 or 600 on my 6½in. mirror. Now I raise a disc with 300, and with 600 the disc is twice as large in diameter, and four times the area. To me this larger disc is apparently much less intrinsically brilliant; but Mr. Franks, if I follow him correctly, asserts that it is of the same brilliancy as the smaller image. Will he explain how the same total quantity of light can be spread over four times the area and remain as brilliant intrinsically as before. There is something in optical theory as expounded by astronomers, which differs much from the theory of light as expounded by Tyndall and Prof. Abbé, for they teach us that diffraction phenomena take place under all circumstances of vision, and irrespective of brightness of objects, while Mr. Franks tells us that the vision of bright points is altogether a different thing to the vision of surfaces less bright. I have always thought the softening of outline with high powers was entirely due to the enlargement of points into discs, and this on planets, moon, stars, or anything else. **W. P. Dodge.**

## AN ADJUSTABLE OBJECT-GLASS FOR TELESCOPE—I.

[24546.]—Having been so fortunate as to obtain the advice and assistance of your able and skilled correspondent "Prismatique" in carrying out a plan which I submitted to him for making an o.g., now the instrument has been received from him, I propose to send some account of it.

The two glasses which form an o.g. are in most cases placed in contact, and when this is the case any errors which may arise in the correction of the spherical aberration can only be remedied by a fresh grinding of one or more of the surfaces; but if instead of having them in contact we place them at a small distance apart, all such error may be eliminated simply by varying the distance between the lenses, and this will certainly be a gain, for many fresh adjustments of distance may be made in the time which would be required for fresh grinding and polishing.. The calculations for spherical aberration should be made so that when the lenses are in contact there should be a slight over-correction of sph. ab., and when this is the case we may always obtain a proper correction by removing them to a suitable distance. Whenever there is over-correction, the lenses have to be further separated, and when there is under-correction they must be brought closer together. And this is equally true for the colour correction also; in fact, the increase of distance manifestly reduces the correcting power of the flint lens in both cases; for, suppose the distance to be increased till it becomes equal to the focal length of the first lens, the spherical aberration of the flint becomes 0, so that for the pair it is reduced to that of the first lens only. Also for the colour aberration, when a ray passes through the optical centre its deviation is 0. And hence the nearer the rays pass to the optical centre, the less becomes the deviation produced. Hence, in both cases, if there is a slight over-correction when the lenses are in contact, either the one or the other aberration may be corrected to any degree of accuracy simply by increasing the distance, and without having to grind lenses afresh. It must be borne in mind, however, that the same distance which gives the best correction for the one does not necessarily do so for the other; and so, perhaps, in practice we shall generally have to give and take—that is, make a slight sacrifice of the one for the benefit of the other, according to the judgment of the artist. It would seem, however, that a small change of distance which would produce a considerable effect upon spherical aberration produces one which would not be nearly so sensible upon that for colour; thus, C and F or C and G will be nearly as good for colour correction, the one as the other; but the difference of distance required for their corrections respectively will produce a much more sensible effect on spherical aberration.

In the belief, then, that the aberrations might be so well corrected, I ventured upon trying whether a larger aperture than usual might not be of advantage, and the telescope was so made accordingly, though not altogether with the approval of "Prismatique." Its dimensions are: Focal length, about 44in.; aperture, 3½in.

"Prismatique" thinks, after making trial, that the arrangement of making curves, &c., is decidedly a good one; but that in some respects, which he has pointed out, a somewhat better one might be made. Anyhow, whatever may be the defects in the architect's design, it is evident that the artist has done his work exceedingly well, and the adjustment of distance, which he says is a much more difficult and delicate operation than might be expected, has certainly been made with consummate skill. And I believe that, in spite of any little defects which it may have, and which certainly seem to be capable of remedy in a future experiment, the instrument may fairly be described as being one of a high class.

I had hoped before this to have sent some account of its performance; but it is as yet unprovided with a finder, and therefore, as the eye which I use for observation is not in very good order, and having, moreover, come to an age when a person can no longer afford to pay attention to ailments which in times gone by he would have looked upon as trifles, the expenditure of eye-power in finding stars compels me to be somewhat sparing in its use.

**W. G. Penny.**

(*To be continued.*)

### MOTION FOR TELESCOPE.

[24547.]—I FEAR that "Montmartre," letter 24508, will not succeed in giving his telescope the proper motions to follow stars of different declinations from any one driving rod or handle; but he may do it much easier and cheaper by using the bladder clock—as I have applied two to my new stand for the 15in. Calver mirror,—and which I will endeavour to describe, so as for any one to apply them to telescopes on a similar stand. Having already described the stand and mounting on p. 189 of the present volume, I shall only add that the tube of the larger telescope is 9ft. long, and 18in. square, and with the mirror, &c., weighs 300lb. The tube for mounting it is the largest gas-tubing I could obtain, being 4in. internal diameter, with the smaller size turning in it. The arms also for directing and regulating the motion of the telescope are longer and stouter, as are also those for carrying the telescope. In other respects it is similar.

Now for the driving of the telescope: The bladder clock I have described before, but will do so again. A square box, 9in. inside and 14in. high, has in it a square of wood that will slide easily up and down, and having a rod fixed in it going through the top of the box, like the piston-rod of the steam-engine. Under this square piston are placed two football indiarubber bladders of the largest size, one on the other, and crossed in the box so that their orifices are in different corners of the box; in these are inserted metal tubes of short length, to connect them by short lengths of indiarubber tubes to a forked metal tube—one bladder to each fork, and the other end of the fork to a long rubber tube to reach to the eyepiece of the telescope. The metal tubes allow the rubber tube to be tightly bound on them, and make an airtight joint. The bladders are crossed on each other, as they rise more equally under the piston when blown into. Openings are made in the corners of the box to allow the tubes to rise with the bladder. These two bladders will give the piston 9in. rise: more bladders may be added if necessary. I find these sufficient.

Two boxes of this description are fixed to the stand—one to the arm for altitude, and the other to the arm for azimuth; this last to an extension of the fast and loose arm behind the post, and they both move with the telescope. On the top of the piston two bricks are placed to keep the piston on the bladders and drive the telescope.

On the top of the piston rod a piece of wood carrying a pulley is so placed as for the pulley to be over the centre of the piston rod.

Motion in azimuth is given to the telescope by the box thus: In the description on page 189 the directions and fixing of the strings are given, but I had better repeat them here. First, a string from the end of the longest crosspiece or sleeve in which the crosspiece turns runs through a pulley on the end of the arm and thence to a second pulley under the arm and near the post, and thence to a weight which pulls the telescope after the star. To control this a second string from the other end of the cross sleeve runs through other pulleys and thence to the gimlet near the eyepiece.

Now, this string is not fixed to the sleeve, but runs through a pulley fixed to the sleeve, and thence to a second pulley on the end of the arm, and thence to the driving-clock. It runs through a pulley on the top of the box of the driving-clock, thence through the pulley on the top of the piston-rod, and is fixed to the top of the box on the other side of the piston-rod.

Now, when the bladders are inflated the piston-rod is 9in. above the top of the box, with the string over the top of it, and this check-string of the azimuth movement is allowed to move just as the air is let out of the bladder, and the piston falls, the telescope following the star as the air is let out of the bladder. The other box for the alt. motion is fixed to the other arm in front of the post and near the far end.

The string for directing the telescope in alt. is not fixed to the end of the tube, but runs through a pulley fixed to the tube, and thence returns to the arm, and by a loop in the string hung on the arm.

When the telescope is to be driven by the clock, if the star is east of the meridian and rising, a string carrying a hook runs from the top of the box, and thence through the pulley on the top of the piston-rod, thence through a second pulley on the top of the box, and thence through a third pulley on the end of the arm when it is hooked in the loop which previously hung on the arm. Thus the descent of the piston will allow the telescope to rise. If the star is falling, a second string fixed to the top of the piston-rod hooks into a second loop in the string from the tube and pulls the telescope down as the piston falls.

The two tubes from the bladder are brought to the telescope near the eyepiece, where the cock of each may be easily regulated to keep a star in the field of view.

Of course, the telescope is equally under control by the gimlet and strings, the clock attachment not interfering with that.

If "Montmartre" will make his stand like this and allow his telescope to be lifted by the heavier counterpoise, and try the gimlet and string plan, instead of the wheel and brasswork, I am certain he will be so satisfied with it as to always use it in future.

I have now had many years' experience of it, and would in no case return to screw motions or rack and pinion.

Also by having his cross piece long on one side and only just protruding from the tee piece on the top of the spindle on the other, he will have his other tube and counterpoise quite out of his way, and require but slight weight to balance his telescope and other tube. His telescope will require no ladder cradle to fix it to the tube; but with two or more rings fixed to the tube, and larger than his telescope, he may wedge his telescope into them with long strips of wood, so that it shall lie as safely as in a box made for it.

Each ring should be made of two flat pieces of iron, so bent as for one end to half-clasp the tube, and the other to form half the ring to hold the telescope. With three bolts and nuts through it, the telescope will be firmly and safely held in any position he pleases.

When used as a day telescope the position will be nearly horizontal, and the greater length of the eyepiece will be no inconvenience.

**Philip Vallance.**

### THE KING'S CROSS ACCIDENT—THE PENISTONE DISASTER.

[24548.]—MUCH obliged to "Midland," p. 457, and of course I do not wish to say anything or to have anything said until after the inquiry; but perhaps "Midland" can help me to solve what has always been a puzzle to me, and that is why "inquiries," as they are called, are always so long delayed? From what I know I have not the least hesitation in expressing the opinion that inquiries into the cause of so-called accidents are delayed in order to bring the evidence into a "suitable" state! They may not be purposely delayed in all cases, I admit; but I confess to a suspicion that there is never any anxiety to strike the iron while it is hot, and have an explanation before time has been obtained to "balance" the accounts of the individuals concerned and "clear the company." I shall probably be told that it is an unjustifiable suspicion; but I am old traveller on suburban lines near London, and have kept my eyes open as well as I could, and I want to know how it is that stationmasters and their subordinates never know anything about accidents beyond the fact that there is a breakdown, and that would-be passengers must do the best they can. Understand me, please: I do not blame the underlings, for they are obeying orders, doubtless; but whose orders are they, and what has a railway company to fear unless it has done something wrong? This policy of mystery will surely recoil on the heads of those who inaugurated it, and the directors or head officials of railway companies will find that honesty is as usual the best policy. For "honesty" in this connection of course read "straightforwardness." Accidents on railways ought to be curiosities, provided you understand the word, for such an affair as that at King's-cross is no more an "accident" than I am Haroun-al-Raschid—I wish I was, for I would make some of the highly-paid "directors" who know literally nothing of the actual working of railways "sit up." At present the majority of them are merely financial speculators, who care little about the arrangements so long as a dividend is declared. It must be so, or the brake question would have been settled long ago. That leads us to the case arising out of the Penistone disaster. Can anyone—does anyone—doubt that if the jury in that case had been in the slightest degree acquainted with railway working they would have brought in a verdict for the defendants? They have practically decided that it is impossible to discover a flaw—an incipient flaw—in a crank axle, and that a good brake, such as the Westinghouse, would not have prevented, or, at least, mitigated the effects of that awful affair. I know very well that experts say they cannot discover these incipient flaws; but permit me to ask whether they have ever tried anything but the ordinary "inspection" of the shops? Have they tested the axles by Prof. Hughes's method, or the simple process of sounding them when slung? If they have, I shall be glad to read a description of their method; but I do not anticipate that I shall be so far gratified, for the whole system is rotten, and there is no "progress" in railway matters beyond the new dimensions which the locomotive superintendent gives to his engines, which are not a bit better than those designed by his precursors. So, in the matter of brakes, you cannot find a jury (12) of disinterested engineers or mechanicians who have any doubt about which is the best brake, and yet you will find directors, who rely upon the statements of the officials, sanctioning the use of appliances which add one more item to the long list of death-traps for drivers. The driver of an express train has always seemed to me to be a bit of a hero—he has, at least, the stuff of which heroes are made, and, perhaps, in the same conditions, would shine as much as those who obtain peerages and pensions. He certainly carries his life in his hand, and to his calm eye and ready hand many passengers unknowingly owe their lives. It is impossible, of course; but, side by side with the "accidents" we read of, what a tale might be told of the disasters just avoided, of the smashes averted, by the cool courage of the engine-driver—the biped in smuts and grease, who is, nevertheless, a "man," every inch of him.

**Nun. Dor.**

### COMPOUND LOCOMOTIVES.

[24549.]—I WONDER that those of your correspondents who were so eloquent recently over the alleged iniquities of the new Mid. 19in. cylinder engines—engines which are, or will be, amongst the finest in the kingdom—had nothing to say about the North-Western compounds. These, as you are well aware, were designed chiefly with the view of reducing fuel consumption. There are two classes of compounds, the small or "Experiment" class, working with 150lb. pressure, and the big or "Dreadnought" class, working with 175lb., and weighing over 40 tons. Both classes, however, really work at pressures considerably higher than the nominal figures, which is to be borne in mind in considering the results yielded.

One fact in reference to the compounds admits of no contradiction—they are unable to attain the highest speeds. Up to about 50 miles an hour they are well enough, but back pressure in the big cylinder, stiffness of working, or some other cause prevents the proper running of the engine when this rate is exceeded. However great the emergency, a compound cannot exceed its normal pace downhill, and thus it happens that if by any mischance time is lost uphill, the train has to come in late, for time cannot be made up downhill. With some of the fastest trains it is all but impossible for the compounds—small ones at any rate—to keep time. No compound yet has ever kept time with the 10.10 between Bletchley and Rugby, or is likely to. I much doubt if they could manage the 12 noon, Euston to Rugby. The facts relating to the speed power of the compounds are more than even sophistry can distort; and whilst, therefore, the number which have been built is cause of astonishment, it is merely another instance of the pertinacity of engineers.

Next to time lost in running comes time wasted in starting. Sometimes compounds have not merely delayed, but have absolutely refused to start at all until assisted by another engine. With heavy trains half a minute to a minute is often lost on starts, especially if the gradient is unfavourable. Of course, other engines do so too sometimes, but not to the extent the compounds do.

It is not easy to get at the coal consumption, but inquiries tend to show that drivers receive no more coal premiums than formerly, if as much. I am induced to believe that no coal really is saved, a view which is supported by the trial on the South-Western. If report is correct, the number of failures with compounds is abnormally high and general repairs expensive. The oil required for lubricating purposes is also very considerable.

There may be amongst your numerous readers someone who will do battle for the compounds, and give us the other side of the case. On the North-Western I have searched in vain for an official or servant who will say a good word for the new engines. Many a time have I been met with the reply, "We must not say anything about them." Everyone dislikes the compounds, though it would not do to express it. Hence the reticence of drivers. But when a driver has a good engine, did anyone ever find him unwilling to expatiate on its merits?

July 26. **Kappa.**

### COUNTERBORE AND FACING BAR.

[24550.]—THE following sketch and illustration of a counterbore and facing bar is contributed by Mr. A. B. Landis to the *American Machinist*. Thinking it would interest your readers I send it over to you. It is inexpensive, and is easily kept in working order, as the cutters will not require replacing for a long time, and when that is required they are cheaply made. In the sketch, Fig. 1 is an end view of the bar; Fig. 2, a side view, edgewise of cutters; and Fig. 3, a side view, showing the flat side of cutters. A is the pin or guide, which is solid with the bar. B B are the cutters, which are inserted in slots on the side of the body, D, of the bar, running the extreme length to the taper shank, as shown. These cutters are plain pieces of flat steel fitted to the slot; the lower ends of these pieces form the cutting edges, and project sufficiently beyond the body D to give clearance to cut the body D is cut out with a milling cutter at G G, which gives room for the cuttings to remove freely. The cutting faces of the cutter radiate to the centre of the bar, making the best

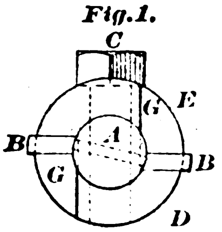


Fig. 1.

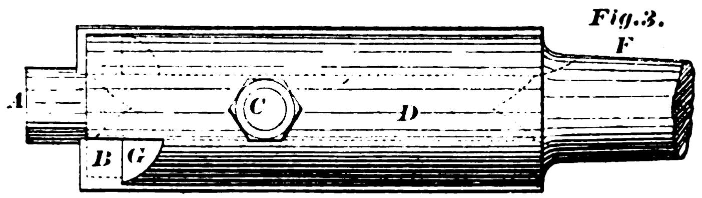

Fig. 3.

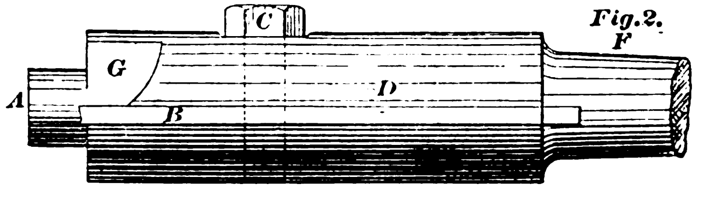

Fig. 2.

possible cutting edge. The body of the bar, D, has a slot, E, sawed through it from opposite sides (as will be seen by dotted lines on Fig. 3), so as to remove as much stock as possible, making the two sides yielding. A bolt, C, passes freely through one side, and is tapped or screwed into the other side. By drawing up this bolt tightly, the two sides of the body D are sprung, and rigidly clamp the two cutters. The cutters can be quickly removed, and sharpened and replaced, as will be seen, and are readily adjustable as to length, so as to make both cutters cut equally. In order to make practically no wear on the pin, A can be turned smaller, and screw-threaded or left plain, and a hardened sleeve either screwed or pressed on it, which can be removed when too much worn and another replaced; but by hardening the pin made as shown, the wear is practically no consideration. The writer made this style of a bar for use in the works where he is employed, and finds it to be great economy, as it is easily kept in order and the cutters will last a long time, as almost their entire length can be used up before needing replacing. Another good feature is that the cutters are solidly backed at the cutting edge, consequently it is almost impossible to break them. We use the bars for facing bosses around holes where bolts are used, requiring true surfaces, but they can also be used for counterboring holes.

Lowell, Mass. **G. F. H.**

## THE HISTORY OF THE TIDAL PROBLEM.

[24551.]—THE evident connection between the period of the tides and the phases of the moon led philosophers to attribute these phenomena to lunar influences long before the true theory was understood. The rise and fall of the tides of the ocean presented a spectacle too remarkable and too important to the social and commercial interests of mankind not to have attracted notice in the early period of the progress of knowledge; but the actual records which we find in ancient authors concerning the tides are exceedingly few and scanty. The reason of this seems to be that the principal seats of civilisation and learning were situated in regions remote from these great oceans and seas, where these phenomena are most developed. As many of your readers who are interested in the subject may not have access to the original sources from which the following sketch is derived, I have thought it desirable to place on record a concise epitome of the progressive results attained by early philosophers in their attempts at the solution of the problem.

The first historical observation of the tides which has come down to our times is probably that of the historian Herodotus, who in Book II. chap. 11, of his great work, speaking of a long but narrow bay, diverging from the Red Sea, in his description of the land of Egypt B.C. 445, says: "In this bay the tide regularly ebbs and flows." Pliny, Book II., chap. 97, as quoted by Lalande in the fourth volume of his "Astronomy," page 8, has the following very remarkable passage on the matter: "That the tides of the ocean ebb and flow is exceedingly wonderful: these are produced under various circumstances, but the cause is in the sun and moon," and he proceeds to describe their course and order very accurately. He died in A.D. 79.

In Lingard's "Antiquities of the Anglo-Saxon Church," chap. 10, we have a succinct account of the knowledge of the subject possessed by the Saxons. "From their insular situation," he observes, "the Saxons could not be ignorant of the interesting phenomena of the tides, and Bede seems to have suspected the existence of that cause, the discovery of which has immortalised the name of Newton." Bede lived A D. 700, and he connected the ebb and flow with the action of the moon, with whose motion they so accurately corresponded that he was tempted to believe that the waters were drawn towards that luminary by some invisible influence, and after a certain time were permitted to return to their former situation. In his work, "De Ratione Temporum," chap. 27, page 116, he says: "The tide is drawn forward as if by certain influences of the moon, and again it is poured back to its natural bounds, when the force alluded to ceases." He does not, however, venture to speculate on the nature of this attraction, but confines himself to the following enumeration of the particulars in which the motions of the moon and of the ocean appear to coincide. "As the moon daily recedes twelve degrees from the sun, so, on an average, the tides are daily retarded four points" (eight and forty minutes) "in their approach to the shore. Some days before the conjunction they seem to increase; and from the fifth to the twelfth, from the twentieth to the twenty-seventh day, they continually diminish. But the gradations of increase and decrease are not perfectly regular, and these anomalies may be ascribed, perhaps, to the impulse or resistance of the winds, more probably to the agency of some unknown power." The Anglo-Saxon, however, was able to correct an erroneous opinion of former philosophers. It had been pretended that in every part of the ocean the waters began to rise at the same moment; but daily observations authorised him to assert that "On the eastern coast of Britain the tide was propagated from the north to the south, and that it reached the mouth of the river Tyne before it washed the coast of the Deiri."

Descartes, after Selencus, as quoted by Plutarch, imagined that the moon, pressing on the surface of the waters immediately beneath it, forced those waters to rise along the distant coasts, attaining their maximum of elevation 90 degrees from the spot at which the moon was in the zenith.

The gravitation of the waters of the ocean towards the moon was clearly understood by Kepler, A D. 1608, although he failed to indicate the law of gravitation. In one of his dialogues he writes: "The sphere of attractive value which is in the moon extends as far as the earth, and entices up the waters, but as the moon flies rapidly across the zenith, and the waters cannot follow so quickly, a flow of the waters is occasioned in the torrid zone towards the westward." And again, in his "New Philosophy," "There are two primary causes of the motion of the seas—the moon and the diurnal revolution. The moon does not act on the seas by its rays or its light. How then? Certainly by the common effort of the bodies, and (to explain it by something similar) by their magnetic attraction. It should be known, in the first place, that the whole quantity of water is not contained in the sea and rivers, but that the mass of earth (I mean this globe) contains moisture and spirit much deeper even than the sea. The moon draws out this by sympathy, so that they burst forth on the arrival of the moon, in consequence of the attraction of that luminary," &c.

Galileo expresses his regret that so ingenious a philosopher as Kepler should give such an explanation as that, a portion of which has just been quoted. His Fourth Dialogue is a development of a treatise on this and other subjects, which was sent to the Archduke Leopold in A D. 1618. His theory was erroneous; but it required a further advance in the science of motion to point out its insufficiency. He attributed the tides to the rotation of the earth, combined with its revolution round the sun. From the earliest ages the problem had been regarded as most difficult, inasmuch that it had been designated "the grave of human curiosity"; so Galileo, having a theory of his own, clung to it with the utmost tenacity. His desire to excel others urged him on its prosecution. There is an unfounded legend that Aristotle drowned himself in despair of being able to invent a plausible explanation of the extraordinary tides in the Euripus. Pytheas, a contemporary of Aristotle, had observed that the full tides occur at full moon, and the ebbs at new moon. Posidonius, as quoted by Strabo, maintained the existence of three periods of the tide—daily, monthly, and annual, "in sympathy with the moon." The College of Jesuits at Coimbra had pointed out the true relation between the tides and the moon, and so had Antonio Dominis; but they failed to apprehend the fact that the same attraction was exerted on the earth as well as on the water, and thus the theory was left incomplete.

It was in A.D. 1640 that Horrox, whose youthful genius stands out so prominently in other scientific researches, announced to his friend Crabtree that he had undertaken the prosecution of a series of observations on the tides. His home was near the mouth of the river Ribble, where the range of the tides is sometimes 30ft. He stated that many interesting particulars had been revealed to him, and he appears to have been the first who undertook the prosecution of these investigations with a thoroughly definite object. His last letter to Crabtree was written only a month before his death, and it seems almost incredible that a youth of twenty-two could have exhibited in his researches such sagacity of thought and such fertility of invention. The obscurity of his position caused him to be neglected in his lifetime; but posterity claims him as one of the most remarkable philosophers that any age has produced.

**James Pearson, M.A., F.R.A.S.**

Fleetwood, July 27, 1885.

(*To be continued.*)

## WHAT IS "CREATION"?

[24552.]—I AM quite willing to accept "F.R.A.S.'s" explanation so far of the mode in which I have employed the word "creation." I have made use of it in much the same way as many people employ the term "electricity," or as he would employ the word, "gravitation"—that is, simply acknowledging it as a source of phenomena which we discern, but cannot ultimately explain.

"F.R.A.S." does not profess to account for the *first* appearance of abnormal forms, though he acknowledges their occurrence. Natural selection presumes their occurrence, but cannot explain it, and all that I have suggested is—and it may be taken only as a provisional theory—that the first appearance of such abnormals may be referred to Creation, no other explanation being forthcoming.

What I meant by "selective creation" is that some new variety having appeared, by means of creation, this new variety is not only liable to be propagated, but, in its immediate descendants, a tendency towards further variations in a similar direction is not unfrequently found, and these variations are explicable only by creation. The sum of these variations may, in many generations, appear as a more constant and distinct variety or species, but such a result is not what one could call a "sudden creation."

"F.R.A.S." will unhesitatingly ascribe to gravitation the phenomena he observes in the movements of celestial and terrestrial bodies, and, being ignorant of what gravitation is, he will do so in humility.

I see no reason why, with like humility, he should hesitate to ascribe to "creation" the phenomena otherwise inexplicable, which he observes in organic nature, even though the *modus operandi* be still more occult; or at least, why he should hesitate to declare, as a true scientist, the insufficiency of natural selection *per se* to account for organic nature as we find it. **H. B. F.**

## FLOWER-POTS.

[24553.]—CAN any of your scientific readers help to me to decide whether unglazed or glazed earthenware is most suitable for use as flower-pots? The common flower-pots become dirty and slimy, and actually, I think, play the part of refrigerators to the roots of the plants, except when they have become hot by exposure to the sun, for after watering, evaporation goes on at the whole exterior surface, with the subsequent lowering of temperature so well seen in connection with the ordinary water-cooler bottles. The shape of the modern flower-pot is convenient, but not particularly noted for its elegance of design; and the question now to be decided is whether something more shapely and economical in glazed earthenware cannot be designed. That the gardeners of China, as also those of that little "Eastern England," Japan, have long used glazed pottery of forms artistic and varied goes without the saying. Even that most primitive of all plant receptacles, a joint of bamboo stem, is glazed with silex outside by Nature herself, and there now seems an opening for our garden potters to emulate each other in the production of well-shaped crockeryware for the garden indoors. But apart from all considerations of shape, permit me to ask whether it would be inimical to plant life to have the ordinary pots glazed. In many cases—perhaps the majority—where the ornamental glazed pots or vases are used, the plant itself is in a porous-pot of common make which is placed within the "china." If any of your readers have had experience in growing plants in the ornamental coloured and glazed vases, will they kindly say if they have experienced any difficulty in cultivation which can be traced to the nature of the "pot."

**Conservator.**

## EXAMINATION OF MINERALS BEFORE THE BLOWPIPE.—III.

[24554.]—Box No. 11.—Greyish white, compact; amorphous fragments, but apparently having a rhombic or rhombo-prismatic crystalline structure: very hard (a penknife leaves steel on surface).

| | |
|---|---|
| I. Powder in B acid. (1.) Faint orange p.c. from bottom of bead at first; green p.c. afterwards unchanged. (2) Transp. and opaque-white mass, very slowly dissolving. | (1.) (2.) Alkaline aluminous silicate, with large prop. of silica and alumina: a very small prop. of soda. |
| II. Added CoO. (1.) Cobalt borate balls, very slowly dissolving to pink (not purple) suffusion. | (1.) Alkali, probably a small proportion of lithia (the potash suffusion is purple). |
| III. Added lime. (1.) Milky streaks at once; with more lime, bead opaque, milk white. | (1.) Large proportion of alumina, and probably, no lime in mineral (*a*). |
| IV. Fragment in E.P. (*b*). (1.) Fuses in part, but remainder dry, exfoliating. (2.) Blood-red, but momentary p.c. | (1.) Not much alkali. (2.) A small proportion of lithia. |

What mineral is this?

Box No. 12.—White, semi-transparent, vitreous, amorphous; hard (penknife causes very little powder, but yields no steel on surface).

| | |
|---|---|
| I. Powder in B acid. (1.) Transparent ice-like mass, *slowly* dissolving (2.) p.c. at bottom of bead for a moment blood-red; afterwards green p.c. unchanged. | (1.) Alkaline aluminous silicate, with little alkali, and much silica and alumina. (2.) Alkali lithia. |
| II. Added CoO. (1.) Very slight pink suffusion; but half the mass not yet dissolved (*c*). | (1.) Not much alkali. |
| III. Added CaO. (1.) Lime balls not decomposed, but surrounded with milky matter, so added mixture (*d*) of CaO + 3 times the mineral. (2.) Bead, milky and opaque; but not all over. | (1.) (2.) Considerable proportion of, but not *very* much alumina. A little soda. |
| IV. Fragment in E.P. (1.) Reddish orange at first; but (2) in strong H.P. (*e*) a pale rose tint. | (1.) (2.) Might be either strontia or lithia; but can't be strontia, which forms balls in B acid like lime. |

What is this Mineral?

Box No. 13. Grey transparent plates or scales, like talc or mica; very soft.

| | |
|---|---|
| I. Powder (obtained by rubbing several plates together on a file, and then crushing between agates) in B acid. (1.) Blood red p.c. from bottom of bead. (2.) Scales (from not properly crushed powder), surrounded by dirty yellow suffusion, all dissolving to vitreous matter, like syrup dissolving in water. Bead, dirty yellow. | (1.) Lithia. (2.) Iron, dissolved by a considerable proportion of alkali, without which the scales would be quite insoluble. |
| II. Added CoO. (1.) All dissolved to pink bead. | (1.) Considerable alkali. |
| III. Added lime. (1.) No milkiness; but bead covered with black slaggy enamel, with (2) white metallic, dendritic crystal on surface. | (1.) Failure to detect alumina, which must be present, from the mineral not being properly crushed. (2.) Probably reduced cobalt. |
| IV. A large scale fused *per se* (1.) (black, magnetic) and powder boiled, &c., in B acid, but many scales still present which give off a vitreous solution. (2.) One or two white opaque balls. | (1.) Considerable proportion of iron. (2.) Trace of magnesia. |
| V. Added lime. (1.) Yellowish-white, opaque, enamel bead. | (1.) Large proportion of alumina with iron. |
| VI. Added CoO. (1.) Co borate balls dissolved to deep *purple* suffusion now, especially over the platinum wire. | (1.) Presence of considerable proportion of potash, in addition to the lithia. |
| VII. Vesiculated bead (*f*) breathed on vesicle, and remelted to a bead BB. (1.) Melts with an intense green light. | (1.) Presence of fluorine; shown here as hydrofluoric acid, to which it is converted by the moisture from the breath. |
| VIII. Original powder in P acid. (1.) Large transparent mass undissolved. | (1.) Large proportion of silica. |
| IX. Bead VIII. crushed and boiled with drop of water in glass bulb (!). (1.) Glass attacked and dulled in neck of bulb. | (1.) Presence of fluorine confirmed. |

This is a most troublesome mineral to handle, on account of the difficulty of properly crushing it. Fortunately, its scaly structure and reaction for lithia render its immediate identification quite easy.

Box No. 14.—White, semitransparent, amorphous, but with prismatic cleavage of fragments on their long axes, (*g*)—soft.

| | |
|---|---|
| I. Powder in B acid. (1.) Considerable effervescence, and on raising the bead to white heat, great and continued effervescence without smell; the green p.c. remaining unchanged. (2.) White, opaque, fringed fragments; no solution going on. (3.) Bead semiopaque, with grey opaline matter. | (1.) This must be a sulphate of some base which retains its sulphuric acid with great tenacity—as barium (*h*). (2.) The reaction of cyanite (a silicate of alumina); but this mineral is soft. (3.) Much combined water. (*i*). |
| II. Powder made into paste with equal part of potash, and drop of water, fused into a ball on Al plate B.B.; ball crushed, boiled, and dried powder in B acid, B.B. (1.) A number of opaque white balls, evolving quantities of opaline matter, and bubbles amounting to effervescence. | (1.) Sulphate of barium, which is the only base evolving opaline matter in this way. Even the fusion with potash, &c., was unable wholly to separate the Ba and $SO_3$. |
| III. Fragment gives a pale green pyrochrome *per se* (1). | (1.) Barium. |

It was impossible to help finding out (and showing) what this mineral is.

Box No. 15.—Yellowish white, amorphous, compact, translucent, hornlike—soft.

| | |
|---|---|
| I. Powder in B acid. (1.) Great effervescence without smell; green p.c. temporarily yellowed. (2.) Clear balls, giving off dense streaks of opaline matter, which soon coalesce into one large transparent ball, not quite round, showing its specific gravity to be higher than that of calcium borate. | (1.) Carbon dioxide, formerly called carbonic acid gas ($CO_2$, test for S on silver here, if doubtful of the fact). (2.) Barium. |

The dullest student can have no doubt of the nature, and therefore, the name, of this mineral.

Notes.—(*a*) Because, if there had been, with such a small proportion of alkali unable to dissolve them, milky streaks (of calcium borate decomposed by alumina) would have appeared in operation I. Still there may be a trace of lime here, to be detected by treating the fused and boiled powder in a phosphoboric acid bead, as before explained.

(*b*) E. P. for "Ellychnine pyrochrome (Greek *Elleuchnion* a wick), made by touching the side of the wick of a candle or wick lamp with the hot assay *while* the pyrocone is being produced. The whole blue pyrocone is then surrounded by a coloured "mantle" of flame of the peculiar colour communicated.

(*c*) It will be observed that I am not fully carrying out my own system. The bead containing the silicious mass should, no doubt, be treated B. B. until it is shown absolutely whether the mass is thus soluble or not; and the sharp practitioner will at once see here that by further treatment B. B. I would probably have obtained more lithium borate to act upon the cobalt afterwards; but I am pressed for time, and consider the above sufficient indication for the identification of a mineral.

(*d*) The mixture is made with a penknife from little heaps on an agate slab, and then ground well together by a superplaced agate.

(*e*) H. P. for hydrocarbonous pyrocone, signifies that the assay is to be held well within the point of the blue pyrocone.

(*f*) There is nothing to *induce* this operation here but the knowledge (obtained from the scaly structure and lithia reaction) that this mineral probably contains fluorine.

(*g*) Found by trying to slice them with a penknife.

(*h*) It is as well to state here that this important reaction (evolving sufficient effervescence to suspect sulphuric acid, the presence of which is confirmed by further intense treatment before the blowpipe and the ordinary test for S on silver) is afforded by no other mineral than barite (or "heavy spar"); fragments of gypsum, the likest to it, being after a time decomposed in B acid B.B. into balls of calcium borate and bubbles of $SO_3$.

(*i*) Barite is said in mineralogical works to contain little or no water; but in B acid B.B. all barium minerals, and even chemically pure baryta, evolve copiously this grey opaline matter, which I believe to represent combined water.

*Remarks.*—As this paper has already extended to the limits so kindly allowed me by the Editor, I shall reserve my remarks on this subject for the letters on "Pyrology," into which I have been seduced or forced by Mr. A. H. Allen, whose evident difficulties of comprehension they will, I hope, help to explain.

**W. A. Ross.**

## PYROLOGY.

[24555.]—The letter of Colonel Ross on "Pyrology" (24514, p. 453) illustrates in a striking manner his method of argument, and the difficulty under which chemists labour who may desire to learn from him the grounds for his views.

As one instance is as good as a hundred, I would call attention to the calcium borate question. Colonel Ross says that if he makes a bead of boric acid on a little loop at the end of a piece of platinum wire, adds quicklime, and again heats before the blowpipe, a ball or sphere will be formed in the clear bead, and may be isolated by treating the bead with hot water. The operation has always been performed by Col. Ross on small quantities of material, the weight of lime employed being, I believe, usually from 5 to 8 milligrammes, or, say, one-tenth of a grain. Col. Ross always finds the weight of the sphere or ball to be just four times that of the weight of the lime employed, so he assumes that it contains 25 per cent. of lime and 75 per cent. of boric acid. Chemists generally, including myself, object that this is not proved, and that a portion of the lime added may remain dissolved in the clear portion of the bead, the ball containing more than 75 per cent. of boric acid. We invite Col. Ross to prove the objection unfounded by looking for lime in the clear portion of the bead by known chemical methods, and by ascertaining by accepted methods the proportions of lime and boric acid actually present in the ball insoluble in water. But to render such experiments satisfactory and convincing to chemists, they must be conducted on reasonably large quantities of material, those hitherto used by Col. Ross being insufficient to establish the composition of his calcium borate balls with sufficient precision, seeing that mere errors of weighing would cause serious discrepancies with the amounts he uses. Col. Ross replies that a distiller might plead for the operation being performed on a bucketful of material, and a smelter would not be satisfied with less than a ton. As a matter of fact, distillers and smelters habitually employ much smaller quantities of material than buckets and tons for their assays; but if they had reason for holding the opinion that nothing less than these amounts would suffice for the purpose, they would be justified in considering the statements of Col. Ross "not proven," if he persisted in operating on quantities and by methods which they did not accept as adeqnate. But Col. Ross appeals to *chemists*, and yet does not think it worth while to use methods which would bring conviction to their minds. Instead of testing for lime in the clear portion of the bead by ordinary chemical methods, he says that no lime *can* be there because it would at once collect and form a ball, which is just what chemists want to have *proved*. It is the woman's argument—"it is, *because* it is." But let it be quite understood that, when chemists suspect lime to exist in the clear portion of the bead, they mean in a condition of *solution*, and not in the form of small balls visible under the microscope. It seems necessary to explain this, for Col. Ross twice quotes me as having argued that some of the lime was "dispersed about the bead." The quotation marks are his, and are liable to convey the impression to readers that I had previously used these words, whereas I have done nothing of the kind, and they are a serious perversion of my meaning.

I may say that there is a very grave reason for doubting the definite nature of any borate of calcium having the composition attributed by Col. Ross to his balls. The simplest formula for a borate of calcium containing 75 per cent. of $B_2O_3$ and 25 per cent. of CaO is—

$$Ca_5B_{24}O_{41}\text{; or, } 5CaO,\ 12B_2O_3.$$

This is, primâ facie, a very improbable constitution for a definite compound, and chemists will want rigid analytical proof of its accuracy before they accept it.

As I said in my last letter, chemists are only too glad to have useful additions made to their methods and tools; but they are sceptical of the value and reliability of processes which the author himself does not appear to consider it worth his while to investigate thoroughly. Personally, if all Colonel

Ross says of his calcium borate balls were proved to be true, I should not abandon the processes for determining lime which are at present in vogue, for, to be of any practical use, it would be necessary for the new process to allow of lime being determined to within 0·5 per cent. of the total amount, in presence of variable proportions of silica, phosphoric acid, oxide of iron, oxide of manganese, alumina, and magnesia. I do not think Col. Ross claims such a degree of accuracy, even when working on pure lime in an unmixed state; in fact, with such small quantities as he employs, such a degree of accuracy is beyond the indications of the balance. I fully appreciate the value of much of Col. Ross's work, and the industry with which he has worked at blowpipe analysis, with the result of devising a number of new methods and ingenious pieces of apparatus; but I think these methods and apparatus have their own proper use, and are as ill-adapted to replace the accepted wet methods of the chemist, as the latter are to replace the blowpipe-methods of the mineralogist, mining engineer, and "prospecter." The difference is a very clear one. When one has a mineral product which is unrecognisable by its physical characters, the work done by Col. Ross is a most valuable aid to its identification: but, when this desideratum is effected, and an accurate quantitative determination of the different constituents is required, wet methods must be resorted to, except in a limited number of very special cases.

**Alfred H. Allen.**

## DYNAMO MACHINERY.

[24556.]—I am obliged to your correspondent, in letter 24512, for his careful reply; but the matter is not quite satisfactory, and I should like to hear further.

There can be no objection to his calculations of the shunt dynamo, as they point to the method of obtaining the greatest efficiency at least cost by increasing the diameter of the iron cores without changing the weight of wire, which is generally adopted in practice. In regard to the experiment with the two sets of coils, they appear to be selected as type of a dynamo that is theoretically perfect.

Now, if these coils are moved to give the effect of a dynamo, in order to obtain the mechanical efficiency of 32 to 1, the large coils must have twice the speed of the smaller coils; if the speed is the same as the small coils, the efficiency is 16 to 1, and at half the speed 8 to 1. To put the case in algebraic form, if at the maximum velocity of induction $C$ is the current produced by a magnetic field, and the number of revolutions of a dynamo is constant per minute, then if the dynamo has double the dimensions, because the armature has twice the diameter, the increased speed of the centre of the wire coils in a Gramme, or the circumference in a drum armature, tends to change $C$ to $C^2$ for the electro-motive force is in proportion to the square of the speed. But by supposition, the maximum velocity of induction is already obtained, and the current cannot increase except by an increase of magnetism; this can only be produced by increased weight of iron or copper, and the theoretic efficiency of a perfect form of dynamo can therefore only be increased by weight, and for any special form is in proportion to the weight.

The increase of efficiency of a larger dynamo when the number of revolutions per minute is constant, is due to the greater speed of the circumference of the armature, which could be got as easily by an increased number of revolutions per minute; but there is a mechanical advantage in construction, which consists in the fact that the same distance may be kept between the field-magnet and armature cores, both in large and small machines; the advantage is, however, very small.

**J. Sutcliffe.**

## TRIPLE COMPOUND ENGINES.

[24557.]—Some years ago I took part in a discussion in your columns which had reference to compound versus single engines. I took what seemed to me the commonsense view, that owners of steam vessels would not have adopted the compound system unless they had good grounds for believing it to be economical. Since those days we have advanced apace, and now the compound has developed into triple expansion engines. At the last meeting of the Institution of Naval Architects, Mr. A. E. Seaton contributed a paper on the triple compound engines, and backed his opinions by some statements which, if not true, ought to be demolished by those who still stick to the simple engines. He said:—As I was quite convinced that economy was due to the system rather than to the higher pressure, it was decided not to increase the boiler pressure more than was necessary to suit the triple system. The other three ships were being fitted with engines having cylinders 25in. and 50in. diameter by 45in. stroke, and supplied with steam of 90lb. pressure from a double-ended boiler, 13ft. 9in. diameter by 15ft. long, having a total heating surface of 2,310ft. so that these engines have every qualification for being economical, so far as general proportions go, the stroke being an abnormally long one and the boiler of ample size. Experience has since shown that these engines are economical in coal, and the wear and tear exceptionally small.

The new engines for the fourth boat were made with considerably shorter stroke, and the cylinders proportioned so as to give equal power; they are 21in., 32in., and 56in. diameter by 36in. stroke, the high-pressure cylinder being supported on columns immediately over the medium cylinder, and in other respects these engines were made as near as possible like the others. Steam at 110lb. pressure is supplied from a double-ended boiler 12ft. 9in. diameter, and 15ft. long, having a total heating surface of 2,270 square feet, and identical in design with the boiler supplied for the other engines. The propellers were made exactly alike in all respects, and the ships being likewise precisely alike, a comparison of the performances of the one fitted with the triple engines could be made with as little grounds for differences of opinion as is possible. One of the ships fitted with the ordinary compound engines was named the *Kovno*, that with the triple compound engines the *Draco*. Their dimensions are as follows:—Length between perpendiculars, 270ft.; breadth, 34ft.; depth of hold, 18ft. 3in.; and of 1,700 tons gross register. They are ordinary cargo boats, built of steel, having a raised quarter-deck and long bridge amidships, but nothing about them otherwise requires comment.

After making a voyage or two to the Baltic, and finding that everything was working satisfactorily, the *Kovno* was loaded with 2,400 tons dead weight, and sailed in January, 1883, for Buenos Ayres; the *Draco* was loaded with 2,425 tons dead weight, and sailed March, 1883, for Bombay, the distance in both cases being about 6,400 miles. It was thought advisable, for purposes of comparison, that the ships should steam at as near as possible the same speed; and to attain this object, we considered the safest plan was to instruct the engineers as to the average amount of coal they were to burn per day, and experience with these ships on their Baltic voyages had fixed this at 12 tons in the case of the *Kovno* and 10 tons in the case of the *Draco*. During the voyage each ship seems to have had fair average weather, and equal care was taken in getting the best results possible. The average speed of the *Draco* was, however, 8·625 knots, or 207 miles per day, the engines making on the average 57·5 revolutions per minute, while the *Kovno* did only 8·1 knots, or 194 miles per day, the engines making 55·5 revolutions. The coal used was ordinary South Yorkshire, just as it comes from the pits for bunker purposes. The indicated horse-power in each case would average about 600. The total coal consumed was 326 tons in the *Draco* and 405 tons in the *Kovno*, or a saving of 19·5 per cent. over the ordinary compounds, with an increase of speed of 6·5 per cent.

In December, 1883, one of the others, the *Grodno*, sailed from Bombay, and attained an average of 8·5 knots, or 204 miles per day, the engines making 57 revolutions, with a coal consumption of 12·8 tons per day, or 469 tons on the voyage. The *Draco's* consumption is therefore 30·5 per cent. less than that of the *Grodno* on the round voyage, and 20·3 per cent. per day.

The success of the triple compound engine was in these instances more than had been anticipated, and induced Mr. Wilson to go a step further. The s.s. *Yeddo* had been refitted with boilers made for a working pressure of 90lb. per square inch, but owing to the size of the shafting the working pressure was limited to 70lb.; the average consumption of coal under these circumstances on two voyages was 17 tons per day. These boilers had a margin of safety beyond what was required by the rules when made, and as the Board of Trade rules had been modified in the mean while, it was found that they could with safety be worked at 100lb. per square inch. A third cylinder was now fitted on the top of the original low pressure, and the safety-valves loaded to the 100lb., and the ship was despatched to Cronstadt. After making two voyages under similar circumstances to the two previous ones, the average consumption was 13·5 tons per day only. In this case it was the same ship, same boilers, same engines, same propeller, and same men, the only difference being the addition of a third cylinder and the increase of pressure.

So far all the trials had been made with two crank engines; so it was now decided to construct another set of engines for 150lb. pressure, having a crank to each cylinder. These engines had cylinders 20½in., 33in., and 58in. diameter by 36in. stroke, and were fitted into the screw steamer *Rosario*, whose dimensions are 275ft. 3in. between perpendiculars, 34ft. 3in. beam, and 19ft. 2in. depth of hold, 1,862 tons gross, and the deadweight capacity 2,550 tons. In March last year she was loaded with 2,530 tons deadweight, and did the voyage to Bombay at an average speed of 8·6 knots on a consumption of 10·5 tons per day of South Yorkshire coal, and burnt on the voyage 347 tons. This result is superior to that of the *Draco* when the size of the ship is taken into account, but is not so much so as might have been anticipated from the increase of pressure and the rate of expansion, which was 14·4 in the *Rosario* and 12 in the *Draco*. Another set of engines was made from the patterns of those of the *Draco*, but with the high-pressure cylinder 20in. diameter, steam at 150lb. pressure being supplied from two single-ended boilers, having a total heating surface of 2,200 square feet. They are fitted in the s.s. *Finland*, a cargo boat 270ft. long, 35ft. beam, by 18ft. depth of hold, and 1,954 tons gross register. In January she was loaded with 2,500 tons dead weight, and sailed for Rangoon. The average speed attained was 8·42 knots per hour, or 202 miles per day, on a consumption of 10·3 tons of Welsh coal per day, the rate of expansion being 12. It should be mentioned that all these ships named are fitted and steered with steam steering gear, so that in comparing these results and those published of the engines made by an eminent engineer in the north of England, an allowance should be made, as in that ship there was no steam steering gear. I have chosen to make all these comparisons by reference to the ships' logs, and to give results such as a shipowner looks for rather than those which engineers prefer to use in forming a judgment on the merits of different engines. I do this for two reasons: first, because the commercial success of the triple compound engine depends on the saving it can effect in a long voyage; and secondly, because I had no reliable indicator diagrams from which the consumption per indicated horse-power could be calculated with any degree of accuracy.

I think these statements, which could be corroborated by the experience of others, support the position I took up some years ago, when I asserted that in spite of its complication and multiplication of parts, the compound marine-engine is more economical than the simple engine. There are still paper theorists who shut their eyes to plain facts, and maintain that with equal pressures the single engine competes favourably with the compound.

**J. B. C.**

## SHIP PROPELLING.

[24558.]—In this age of inventions and rapid development of various industries, it is no wonder that men of genius are ever racking their brains to devise a quicker, safer, and cheaper means of propelling vessels.

I have had the pleasure of an interview with a most respectable working man (an engine-man) who has devoted many years of study to this particular subject, and he is fully convinced that he has perfected a mechanical contrivance that will entirely obviate all resisting weight, or what is perhaps more correctly termed "back weight," and reduce "the slip" by 90 per cent.; also an increase of 500 per cent. of grapple over the most modern appliances, reduce the speed of the engines from 40 to 50 per cent. at the same time doubling the speed of the vessel with an accompanying reduction of 50 per cent. of fuel and 50 per cent. less weight in the engines and appliances; consequently, half the space will only be required for machinery, &c. More than that, the engines will not occupy the most valuable part of the vessel as by all other inventions, but will be situated aft. Most of the existing vessels could with very little expense be altered to suit this invention.

The mode of propelling is by a system of paddles so arranged that the engines cannot move them through a given space without moving the vessel through an equal space less 10 per cent.

There are various minor improvements and modifications that simplify it throughout; so that if it is really capable of performing what my friend asserts is a fact, then the distance between Liverpool and New York will be accomplished in little more than three days, and the greatest revolution in navigation will have been achieved that this 19th century has witnessed.

My object in writing to you is because I thought if a publication so widely patronised as yours would kindly insert my letter, it would be the means of bringing this matter under the notice of those interested in ship propelling, for the inventor living so far inland is removed from every one who is interested in the subject.

If anyone is desirous of obtaining fuller information I shall be pleased to give it them.

**W. Griffin.**

## SIR EDMUND BECKETT'S "CLOCKS AND WATCHES AND BELLS."

[24559.]—Allow me to point out the following errata in 7th edition of Sir E. Beckett's "Clocks and Watches, and Bells." P. 62, line 14, for "brass," read "glass." P. 199, line 91, for "J," "J," read "S," "S."

I am sorry to say that both Fig. 26, on p. 141, and accompanying description are incomplete, and that the apparatus, as figured and described, would fail to work as intended.

We find the four-year wheel (Y in Fig. 26) is moved on, *one pin* at a time, by the "click" on lever L M; and that L M is actuated by gravity, its end resting on the snail-shaped cam, fastened on the arbor of wheel M, and L M falling once a month, as wheel M takes that time to rotate. Therefore the wheel Y can, and does, turn on its arbor only one pin at a time, and that but once a month as often as the cam on M rotates.

Suppose it is now Feb. 26th in an ordinary year, and that the wheel Y has not been moved since the month came in, we also see that the tooth E on lever D C will fall against Y once in 24 hours, as the "one-day" wheel, D, revolves. The falling back of lever D C will occur soon after midnight, as the indices of calendar clocks usually move at this time when the new day begins.

At midnight, then, on Feb. 26th, the pin D pushes lever D C aside until the dial records "Feb. 27th," and the lever is free from the control of pin D; then spring at C throws over D C until its movement is stopped by tooth E on D C, banking against edge of Y, and the length of E is made just sufficient to permit click G to trip over and pick up one more pin on dial wheel M.

As midnight of 27th approaches D C begins its movement to the right again, and G takes its pin along, so that at midnight the index is advanced one step and registers "Feb. 28th." As before, in due time pin D sets lever D C free to fall back toward Y and D C falls. How far ought D C to fall this time? Must it pick up only one pin on M and register the 29th next? No; this is not leap year, and we have no Feb. 29 in it. Hence, the click G must trip over pins Nos. 29, 30, 31, and get hold of and bring forward pin No. 1, so that at midnight it may register March 1st.

To secure so deep a drop as this a notch is filed in the edge of Y, deep enough to let E fall four depths instead of one only; furthermore, it is plain that Y must have been moved so as to place this notch in position to catch E at some time before D C falls back soon after midnight of the 27th, and it is equally plain that Y had not moved when D C fell back 24 hours previous. In other words, the cam M must have moved and dropped off the lever L M during the 24 hours alluded to just now.

So far all is plain; but at midnight of the 28th click G advances, not now with one pin only, but with a mouthful of pins—*i.e.*, 29, 30, 31, and 1—and the index marks, as it should, March 1; and by gradual advance of pin D, the end of lever D C is at last free once more to drop, abutting, as before, against Y.

As the next date is March 2nd, the tooth E must drop this time only far enough to let G pick up one pin on dial wheel M; but the deep notch in the edge of Y is *still in position*, and the tooth E must go four depths instead of one, and register March 5 instead of March 2nd, and from this the dates would be all in confusion.

As the mechanism is now arranged, it is clearly impossible to remedy this, for there is no way to move wheel Y except the lever L M falling off cam M once a month, and, as said cam has already dropped the lever on the 27th Feb., we must wait till M revolves again.

Sir Edmund evidently forgot that, after providing means to move wheel Y into position, he must also find a way of removing the deep notch when its usefulness was gone. Of course, the same trouble would occur at the ends of all the short months, as well as on March 1st. Two movements are therefore necessary: one to put the notch *under* E as the short months close, and another to promptly *withdraw* said notch as soon as the tooth E is lifted out of it.

The "Ithaca Calendar Clock Co." do this by using a year wheel and a four-year wheel; but as I have not yet examined the interior of their clocks, I can give no idea of the plan employed. Sir E. Beckett will, no doubt, remedy the oversight now that his attention has been directed to it.

On page 145, note at bottom, Sir Edmund gives his views on the orthography of the expressive Americanism "buncombe," and insists that "bunkum" is the true way, the other being altered by someone who knew of "the noble house of Duncombe."

The absurdity of this explanation is very laughable when one reflects that of all who have occasion to spell this word in America, not *one* in *ten thousand* ever heard of "the noble family of Duncombe"!

If Sir Edmund possesses a good atlas of the United States, I wish he would look at the map of North Carolina, and he will there find, in the extreme western part of the State, and intersected by the Blue Ridge, the little county of Buncombe.

Its population has always been largely of the backwoods class, and somewhat illiterate, while proud.

Many years before the Rebellion this county was once represented in the State Legislature by a backwoodsman who had been appalled all the session by the new ways of life he had met with at the Capitol, and so had kept as "mum as a mouse." Finally, on the last day of the session, he paralysed the "Patres Conscripti" by bursting out into a long and flowery speech, evidently committed to memory and utterly mal-à-propos of the bill under consideration.

After adjournment the members anxiously asked the source of his sudden inspiration, and were informed that his county expected to hear from him in the papers, and therefore he had prepared his speech. "In fact," said he, "I care nothing for the bill under discussion, I am merely talking for Buncombe."

This is the origin of the phrase. It is not "bluster"; but when a man talks with no object in view but hearing his own voice, or making an impression on the "ignobile vulgus," it is "talking for Buncombe."

**Roi ne Puis, Souza Je suis.**

## WARPING AND CRACKING OF CASTINGS.

[24560.]—I note your article on the "Warping and Cracking of Castings," and the difficulty occasionally in getting the core removed in time to allow for shrinking. I beg to say that I got over this trouble by using "hard loam bricks" in some class of goods. When the castings were thin they were used one over the other the whole depth of the mould, and a strong pointed bar would cut a passage down in a minute or two; in thicker castings, they were built in, so that the bricks broke the joint. **W. S.**

## TWO EYES ARE BETTER THAN ONE.

[24561.]—Mr. Nelson, in his letter 24511, writes:—"A one-eyed man sees every whit as well as a man with two."

Mr. N. surely knows of the advantage of keeping both eyes open when using a telescope; if not, any sailor will show him. **W. R. Kennan.**

## IRON AS AN ELEMENT IN THE BATTERY.

[24562.]—What is the reason that iron is not used instead of zinc in the battery? I have read of some objections, but cannot they be overcome in some way? I was reading the other day some remarks made by the president of a society in Glasgow on this subject, and I should be glad if your readers would ventilate the matter for our benefit. These are the remarks which attracted my attention more particularly:—

Iron has been frequently used as the electro-negative element of a battery, especially when in the passive state, by contact with concentrated nitric acid. Probably the objection to its use as an electro-positive element has arisen from earlier experimenters finding local action uncontrollable, which in the case of zinc was easily obviated by amalgamation. I have recently made some experiments in this direction; in point of fact, constructing a sulphate of copper cell, in which the copper is used in contact with sulphate of copper, as is customary in Daniell's cell; but the zinc is replaced with iron used in contact with protosulphate of iron; and find that three of such cells connected in series decompose water, so that the electromotive force is probably what theory indicates, about two-thirds that of a Daniell cell: moreover, such a construction of battery gives what the chemist dearly loves—a chemical cycle easily worked, restoring the chemicals to their original state. The solution of sulphate of iron produced by the battery on evaporation and distillation yields sulphuric acid (or sulphurous acid) and peroxide of iron, the former ready to be combined again with the deposited copper, and the latter ready for the blast-furnace and reduction to metallic iron. I find a form of cell similar to the Sir Wm. Thomson or Medinger cell, with some practical alterations in detail, to suit best, which, requiring no porous cells, can be made of any dimensions. A saturated solution of sulphate of copper contains one-fifth of its weight of the salt, and it floats upon a saturated solution of sulphate of iron, which contains only about one-third of its weight of the salt, so that if the sulphate of iron is drawn off as a saturated solution, the copper plate requires to be at the top and the iron at the bottom of the cell.

If, however, saturated solution of sulphate of copper be put into a bell-jar, and metallic iron be placed in the upper part of the jar, the copper is replaced by iron, and we have a solution of sulphate of iron half-saturated floating upon a solution of sulphate of copper fully saturated. The line of demarcation between the two solutions remains quite distinct for weeks, and very little diffusion occurs; consequently a very manageable cell is made by a horizontal copper plate being put at the bottom of a cell containing a saturated solution of sulphate of copper, and one or more vertical iron plates being placed above in half-saturated solution of sulphate of iron. The solution of sulphate of iron is easily protected from the action of the atmosphere, and consequent decomposition, by means of a thin layer of mineral oil. If from time to time a solution of sulphate of copper is poured down a wide tube, reaching to the copper plate, the iron solution being simultaneously drawn off from a higher level, a constant battery is constituted, which involves no cost in working beyond that incidental to the removal and recovery of the products, and which throws no product into the market the sale of which would be doubtful.

More plate surface, however, requires to be used with iron than with zinc, but iron is only one-fourth the price of zinc. I have found that three iron cells only give two-thirds of the electrolytic action given by two zinc cells, so that in practice probably the iron plates require to be double the size of the zinc plates for equal currents of electricity; but even then the arrangement should approximate in economy to the cost of lighting by the dynamo. It is obvious, also, that torrents of electricity could be evolved from the iron used in precipitating copper by the wet process of Henderson and others, if tanks be arranged in a similar way.

What do our electricians and chemists think? Anything that would cheapen the battery current considerably would be of great value; but I suppose there is no hope of competing with a dynamo. **J. T. M.**

## GINGER ALE.

[24563.]—As this is the season when all sorts of beverages are welcomed by the thirsty, the following process of making ginger ale, given by a correspondent of the *Mineral Water Trade Review*, may be useful to some of your readers:—

Select a good sound unbleached ginger; Jamaica may be preferred, although I found a fair sample of Cochin yield a very good extract. The great aim is as far as possible to insure the freshness of the root, as ginger loses a considerable amount of its peculiar odour by long keeping, although its pungency remains almost unchanged. The extract is prepared by pounding 20oz. of the root into a coarse powder, which should be rendered uniform by passing it through a sieve of forty meshes to the inch; the granules thus obtained are mixed with a sufficient quantity of dilute spirit, composed of equal parts of alcohol at 60°, and distilled water, so as to form a paste, which is placed in a percolating apparatus, and left to macerate for 48 hours. Next pour on dilute spirit, so as to obtain 70oz. of tincture; press out the marc strongly, and finally add sufficient liquid to make up 80oz.

Of the tincture thus prepared, take 7oz., mix with 6 pints of water and sufficient kaolin (China clay), or thoroughly washed whiting may be used; filter through paper so as to obtain a perfectly bright filtrate, in which dissolve 6lb. of sugar without heat. This quantity will be found easily soluble in the above proportion of water.

This forms the first part of the process, which is completed by the addition of 140 drops of tincture of capsicum berries (obtained by macerating 8oz. of the bruised berries with 25oz. alcohol at 60°, and 25oz. distilled water, and proceed as in making the essence of ginger; the product should measure 50oz.); also 180 drops tincture of vanilla (made by macerating 1oz. vanilla pods, thoroughly bruised in a mortar, with 2oz. distilled water and 8oz. alcohol at 60° for eight days); also 6 drops essence of cloves (essential oil of cloves 1 part, alcohol at 60° 9 parts) with 30 drops essence of lemon, which quantity will be found perfectly soluble in the syrup, providing that the quality is good, and 2oz. of citric acid dissolved in 6oz. of water.

The syrup thus completed may be coloured by the addition of burnt sugar as required, and finally filtered with a little paper pulp in the usual way. One ounce and a half is the requisite quantity for each bottle. If it is deemed necessary to give an extra amount of foam more than exists naturally in the ginger, a most efficient heading may be obtained from the following formula:—Soap-wort root (*Saponaria officinalis*) in coarse powder, 4oz.; animal charcoal, 2oz. Macerate two days in a mixture of alcohol 60°, 4oz.; pure glycerine, 4oz.; distilled water, 8oz.; then percolate so as to obtain 11oz. of finished extract. Two drachms of this will be found sufficient for 1 gallon of syrup.

**T. T.**

---

In the *Bulletin de la Société d'Encouragement pour l'Industrie Nationale*, M. Carnot, in a report presented by him on behalf of the Committee of Chemical Arts, showed that the cause of the corrosion of sheet copper employed for the sheathing of ships is the presence of cuprous oxide, which, in contact with salt water, occasioned the formation of soluble salts, even when the air is excluded. In order to reduce more completely the oxygen compounds present in the copper, he introduces a small quantity of metallic manganese, which completely reduces the cuprous oxide remaining in the metal, and becomes converted into a manganese silicate, in contact with the sides and the sole of the furnace. If a few thousandths of manganese remain alloyed with the copper, they affect neither its malleability nor its resistance to the action of sea water. The manganese is introduced in the form of cupro-manganese, an alloy containing 75 per cent. of copper, and 25 of manganese.

# REPLIES TO QUERIES.

**** In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[56440.]—**Warnerising.**—To "ALTO PETIT."—Many thanks for notice on p. 436 of query on the above subject. I should be obliged if you would favour me with the number and date of patent, or further particulars of process.—R. M.

[56676.]—**Free Reeds.**—I am sorry to be again necessitated to reply to "G. L. B.," p. 457, in connection with this query. That gentleman still fails to comprehend the exact requirements of the querist. May I again remind "G. L. B." that the querist requires to know how to tune reeds, but evidently does not know how to proceed? I now inform "G. L. B." (in reference to the various prices charged for reeds) that 18s. is a price charged for a set of reeds of medium quality, and that some dealers even charge 20s. and 25s. a set, so that, under these conditions, 18s. is not the highest price charged, and the reeds which you obtain for this amount could not, in consequence, be "the best." These prices, viz., 18s., 20s., and 25s., are those of local dealers in reeds, and are therefore much beyond the usual prices of sets of reeds from the makers. This answers "G. L. B.'s" inquiry on p. 457. For the benefit of the querist, and those interested, I submit a few practical remarks and hints on the subject of tuning reeds. 1st. Harmonium reeds are not "tuned" (in the true sense of the term) by the method suggested by "G. L. B." in a previous reply. The reeds are merely filed up roughly to pitch, and require to be carefully tuned when they (the reeds) are screwed on the soundboard or pan. 2nd. American organ reeds, in most instances, are voiced and tuned in a tuning apparatus which is used in the various factories in which American organs are made. These reeds, like those used in harmoniums, require a little refining in tone and tune, when they are placed in the instrument in which the reeds are intended to remain. 3rd. In 99 cases (if not more) out of every 100, when American organ reeds go out of tune, it is caused by the dust (which is continually being drawn into the instrument) adhering to the tips of the vibrators. This has the effect of flattening the reeds, and so causing them to sound out of tune. In this case it is only necessary to remove the vibrators, and carefully remove the dust from them. When replaced in their tubes, after this operation, they will be found to be in tune, unless the reeds are corroded through exposing the instrument to the damp. In the latter case the corrosion must be removed, and this will afterwards necessitate the tuning of the reeds. Each of the described operations should only be done by persons familiar with the construction and care of American organs. To those who are not acquainted with the method of tuning reeds, I may now inform them that when a reed gets out of tune it goes flat, and requires a slight scrape on the tip of the reed, which will, in most cases, bring it in tune again. The latter remark applies chiefly to harmonium reeds. If "G. L. B." considers it necessary to describe the "tuning bellows" used in reed-organ factories, I have no objection to kindly request him to do so, particularly as he evidently thinks that I am not acquainted with it, which idea, I may respectfully inform him, is utterly incorrect.—G. FRYER.

[56784.]—**Bicycle.**—The best way I find is to grind or file the face of both bearings, for I have them to do nearly every week, as I am in the trade, but I find that it always answers the purpose.—JOHN COOPER.

[56835.]—**Copy Drawings.**—If "W. R. A." will look on p. 242, and through the indices of his back volumes for references to articles on this matter, he will, after reading and making a few more trials, be able to put a more definite query. Full particulars of the ferro-prussiate process have been given, and I suspect it only requires a few more experiments for the querist to succeed.—E. G. M.

[56848.] — **Grinding Pearl Barley.** — The querist can compel the dust to go into his loft by means of a powerful exhaust fan; but exactly how that is to be arranged remains to be settled when further details are given.—ESSAR.

[56851.]—**Small Motor Castings.**—Would it not have been better for this querist to have returned one of the F.M.'s, and obtained a proper match? Mere difference in weight might not make much difficulty; but another pattern is awkward.—T. J. M.

[56853.]—**Writer's Cramp.**—I am afraid there is not much that is satisfactory that can be said to this querist. If he has been under a specialist who has failed, there is not much reason to suppose that any advice given in these columns could do him good. Alleged remarkable cures by the gentleman he names have been published in the *Lancet*, and he might communicate with Dr. A. de Watteville, of St. Mary's Hospital, Paddington, W., with advantage.—SCRIBO.

[56879.] — **Ferrotype Photograph.** — I am afraid this photo. is irremediably spoiled; but if it is of any special value, I would recommend querist to consult an expert photographer, who would no doubt put it right if possible.—T. M.

[56937.]—**Tons Measurement.**—Tons measurement is the tonnage of a vessel calculated according to her length, breadth, and depth. Tons burden is the amount of cargo she is capable of carrying, and is found by calculating every forty cubic feet of cargo space as one ton.—JAMES MCCASH GOVAN.

[56940.] — **Manufacture of Aluminium.**—Evidently A. H. Allen could not have read my answer to the above with much interest, or else he cannot know much about it, or he would not have contradicted the answer to the query on the subject. It distinctly says on page 418 that "In order to complete the process, and convert it into aluminium, the aluminium chloride is treated with sodium, in order to withdraw the metal. The operations are completed in a few days, &c., &c." The Webster process is a simple and successful one, for all the by-products are regained. The potash and sulphur are extracted, the iron thrown down as a fast and splendid blue, while the residual sulphuric acid is concentrated for use. But the chief advantage is its supersession as a dry and speedy process over the old and cumbrous method of precipitation, by which enormous quantities of substance had to be handled, and a bulky and gelatinous mass produced, requiring a great length of time to dry before being fit for use, and was even then contaminated by impurities. By the new way, the alum requires but twenty-four hours for conversion into the dry and pure alumina. Using three retorts of 2cwt. capacity for the anhydrous alum, the Aluminium Crown Metal Company, at their works near Birmingham, produce two tons weekly (1883) of the oxide at one-fourth the cost of the precipitation process. The alumina thus obtained is balled with charcoal and salt, made into chloride and reduced for metal, the aluminium obtained being perfectly pure, containing no iron, the least trace of which is fatal to its use for alloy. Bars of aluminium bronze (Webster's process) have not broken till a strain of 42 tons per square inch was applied.—P. E. W.

[56948.]—**Gas-producing Apparatus.**—Replying to (1) I would state that I can only give you an approximate size, because you have omitted to tell me whether the engine inspires its charge and fires on having completed, say, one-third of its outstroke; whether every outstroke it fires the entire cylinderful compressed, or whether it is of the Otto type? At any rate, the sizes I should give as approximate would be air-pump 6in. bore by 3in. stroke. The generator surrounding it may be square, if you like. In the absence of the data wanting above, I cannot give you anything like a reliable reply as to the extent of the minimum safe sum wanted in the generator. (2) I would not advise the air-pump being made square, because it does not need to be bored, and the flanges, if turned, are handier round than square, whilst the angles of a square would, in my opinion, be likely to cause damage very soon to the diaphragm. (3) Benzoline and gasoline are not the same thing, although derived from a similar source, and gasoline is certainly by far the best gas producer. (4) As the cost of the gas is relatively that of the gasoline, the cost per 1,000ft. I should put down at, say, 6s. A gentleman who uses this in quantities says his gas costs him but 5s. 3d. a 1,000ft. The strength of gasoline gas is in excess of coal gas, as shown by the indicator diagram; but apparently the expansion is not so well maintained. Should you desire, by advertising your address, I would draw the attention of the firm who now make this apparatus commercially to it, and have no doubt they would supply a set of castings very cheaply. You would find the pattern making for it somewhat troublesome. I made one for myself, and it was a lengthy job, owing to the core-boxes and parts needed to get the passage ways, &c.—INVICTA.

[56949.]—**Aluminium and Calcium.**—To MR. W. J. GREY.—I intend taking your advice respecting Al, and shall include Ca and Mg. I must differ from you respecting the properties of Ca. It is now six months since I made my last sample, and it remains unalterable. Four years since I made an alloy of Ca and Ni, and deposited a beautiful white metal. I also alloyed it with Cu, and produced a rich gold colour. The salts for plating with Ca are far more economical than Ni salts. The CaO can be so easily obtained at a trifling expense, that it appears to me to open a new field for enterprise—particularly as an alloy.—F. W. GERHARD.

[56950.]—**Lead Burning.**—In your issue of the 24th, Mr. P. J. Davies takes an unfair advantage of us. We received a memo. from him on the 17th inst. of more or less the same tenour of his communication to your journal. We answered him, saying we were unable to forward a machine, having a large shipping order to fulfil which took the whole of the machines we had in stock, but would make an appointment to meet him as soon as we had another ready. Would it not have been more fair to have waited a reply from us, instead of rushing into print so early with his reply (*sic*). How can he positively say, "I cannot speak in favour, &c.," especially when he has not tried? Would it not have been more English-like to have said: Not having as yet tried or tested Briggs and Co.'s lead-burning machine, I will withhold my opinion until I have done so? He speaks disparagingly of the specimens of lead burning at our exhibit. May we ask, Did he go with an unbiased opinion, or with (as we think) a jealous feeling? Will he inform us what is wrong, and what is faulty? Probably he has made a mistake, and what he takes to be wrong or faulty, a less practical man will prove to him is an improvement. In this age we live and learn, and we must say that one person has yet something to learn, though perhaps he will not admit it. We cannot expect a favourable or unbiased opinion from Mr. Davies if this is the way he takes an unfair and non-tested advantage of our machine. We do not pretend to say that the burning is done by a professional lead burner, but only wish to prove "that it will burn lead," and that the machine is handy to carry about, being always ready for use, and does not require preparation with acid or spelter.—BRIGGS AND CO., 58, Rokeby-street, Stratford, London, E.

[56956.]—**Ball Bearings.**—Charles Hosken is of the same way of thinking as the writer used to be. For several years he condemned these bearings and rode machines with parallel steel collars. About four years ago he bought a bicycle with ball-bearings to front wheel, and at once found out his error, and has since ridden machines with ball-bearings to both wheels and pedals also, and as long as he can get them does not intend to have any other. Besides being easier of propulsion, they almost dispense with the use of oil and its attendant mess. In the matter of road grit they are about on a par—it very soon destroys either if allowed to get in.—R. R. N.

[56956.]—**Ball Bearings.**—Would Mr. Hosken (p. 458) give me the name of one of those "first-rate riders" who are "opposed to ball bearings," and, referring to his remarks about "new-fangled ideas," can he tell me of any amateur, maker's amateur, or professional, who would engage in a race that he really wanted to win, except on a bicycle having ball bearings? This question was argued at some length many volumes back; but until we get a perfect bearing, in which the axle is always separated from the bearing by a film of oil, I imagine that those who want to win "pots" will always use balls.—ESSAR.

[56956.]—**Ball Bearings.**—I think that Mr. Chas. Hosken would be doing good service if he would let us know what bicycle bearings he would recommend, and why? It is easy to say "Have nothing more to do with ball bearings"; but to those who have always looked upon double ball bearings as the best one could have, it is not easy to do so unless we have reasons given why others should be preferred. Taking a bearing to mean the part through which the axle revolves, it is not easy to see how perfection is to be reached. It seems to me that there must be friction in three different directions, one vertically and the other two laterally—viz., one to keep the forks up against the wheel, and the other some contrivance to prevent the bearing itself from working outwards. I cannot see how anything better than balls can be contrived to answer these purposes as long as the balls are kept quite clean and well oiled. Cones would probably be very good if metal could be got sufficiently hard to resist all wear; but if once a groove begins to cut the bearing must be bad.—J. R. T.

[56969.] — **Hydraulic Ram.** — Our friend "W.A.S." misquotes my statement at page 458, as it was not my intention even to say that, nor did I say so. What was stated may be made more clear by explaining that: Supposing the valve to be open, and water flowing steadily and quietly out, the water would flow round and over the valve without closing it or lifting it to its face. But let the same water, under the same head, flow out with speed, at a given rate of speed, the water would, pressing on the under side with a power equal to the head and the speed, quickly close it; and, supposing that no recoil took place, would, the valve no longer being in partial equilibrium, still hold the valve to its face, and the ram would cease to work. But, as I have before stated, there is a recoil; the valve therefore falls, due to a superior pressure above it, and partly by gravity. We will assume it has fallen, and also assuming it was not loaded to represent the statement I made, the least speed of the outflowing water would close it again, long before the falling column had attained a speed sufficient to force water more than a very small height. Therefore, for a nominal lift, the conditions are very simple. It was for this reason that I made the statement I did, and my inference was intended to mean (and the querist states he knows the principle of the apparatus) that the valve must either be in itself, or, as made by a well-known maker, of such a weight that the flow of water has time to gain sufficient speed to acquire the necessary momentum required to force the water on the delivery. General Morin's work I know and have; but I do not by any means agree with him on all points. It is not reasonable to waste time and space on such a matter. I could point out several items. Still, on the whole, the book is both interesting and instructive.—INVICTA.

[56977.]—**Strength of Beams.**—"A. B." inquires the relative strengths of beams: 1st, a bar 4in. deep by 2in. wide; 2nd, a bar 3·8in. diam.; 3rd, a bar 3·5in. square. Answers have been given by "J. S. C." and "Dubliniensis." That given by the latter does not appear to be clear to the former (see p. 439), and I must confess neither of them is clear to me. I have always understood that the strength of beams varies inversely as the length, directly as the breadth, and directly as the square of the depth, or in a formula as $\frac{B\,D^2}{L}$. This rule is that given by Goodeve, Anderson, and several others, and if correct the strength of the first would be represented proportionally to the others by the number 32. In the second and third cases as $b = d$, the strengths would be 3·8 cubed or 54·87, and 3·5 cubed or 42·88 respectively. But by this formula it follows that a square and round bar of equal thickness would have the same strength, which is inconsistent, seeing that the areas are as 1 is to ·7854. I shall be much obliged to the two gentlemen referred to above, or other readers of the "E. M." if they will kindly explain the matter further for the benefit of the original inquirer, and of—F. A. R.

[56679.]—**Supported Beam.**—I beg to apologise to "J. S. C.," for contradicting his assertion that there is no strain at the centre of the beam. I did not take the statement in its strictly mathematical sense. Of course, the centre is a point, and has no magnitude. The strain upon the point is therefore infinitely small. In concluding, I must compliment "J. S. C." upon the power which he possesses, in common with Prof. Goodeve, of leading the readers of his writings into literary traps.—BACCHUS.

[56997.]—**Hydropathy.**—For nervous debility a strong brine made of Tidman's sea salt is very strengthening. The same water can be used more than once. It had better, perhaps, be slightly tepid, and the sponge merely dipped in the water and rubbed over the body, which is less exhausting than a large volume of water. I would strongly advise "Quixote" to leave off tea and coffee, both of which act injuriously on nerves and stomach, as I found, bringing on migraims and sleeplessness. Milk, boiled or cold, and diluted with water if preferred, is a nerve-strengthener, also Schweitzer's cocoatina, a small quantity of which is sufficient, as I find it digests better when weak.—C. M. Y.

[56997.]—**Hydropathy.**—"Quixote" may be unable to go to a hydropathic establishment, as advised last week in the two replies to his request. He says "he has nothing but a tub and sponge, and is probably wrong in his mode of procedure." In my plan not even a tub or a sponge is needed; nothing that is not already in the room, and yet I derive much refreshment and invigoration from my "hydropathy." All I do is to pour some water into the hand-basin, wet a corner of a towel, squeeze it a little so that it is wet, but does not run, and then wet-rub a division, and only a division, of the body. Then I at once dry-rub the part wetted with a dry and coarse towel until it is dry and comfortable—not wet, or damp, or chilly. I then do the same to the other divisions, and the process is complete, and I feel refreshed, enlivened, and strengthened, and that what I have done has done me good. I make three divisions—(1) chest and one arm; (2) a leg and the other arm; (3) the other leg and the back. It takes 8 to 10 minutes to do the whole job. Not much water is needed. There is really but little to remove from the skin unless one is engaged in dirty work, and the water I find is only clouded—like rinse water, in fact. There is no splashing or mess made, and nobody knows whether I do it or omit it. Now for a great secret, especially for the weakly and nervous. I do not *chill the feet*, or stand in any tub or pan, or on a cold floor or oilcloth: washing the feet or head is done at other times, and forms no part of my morning's ten minutes' "hydropathy." I am careful directly I take my warm feet out of bed to put on my socks and keep my feet warm, and my system admits of that, while most plans do not. "Quixote" should make that his key-note; secondly, by working in divisions, I prevent the evaporation and the chilling of the body incidental to the plan of wetting all over at once. If "Quixote" will avoid these two great evils, and "do" his head and feet somewhen else, I am satisfied that he will find great benefit obtainable without any "apparatus"—without even a tub or a sponge, and without any "establishment."—NO CHILL.

[57022.]—**Perchloride of Iron Battery.**—To "SIGMA."—This battery, which is called a new one, is like most of these new and patent batteries—very old. I tried it myself over thirty years ago, and it will be found mentioned and slightly explained on p. 159 of my "Electricity," 2nd edition. The source of the energy is the reduction of perchloride of iron to protochloride. The proposed gain is in the spontaneous regeneration of perchloride through the agency of atmospheric oxygen. The battery is, in fact, a Bunsen, in which the zinc is replaced by iron with greatly reduced force, and the nitric acid replaced by perchloride of iron, also with lessened force. It gives off no fumes, and that is its only merit; but it polarises very quickly, and its E.M.F. is low. "Ex-Garrison Gunner's" difficulty arises from his supposing that the actions are equal and opposite, the similar formation and reduction of chloride of iron, forgetting that these are two chlorides. The iron is not reduced and then oxidised by the air, but perchloride becomes protochloride, and then the air in presence of excess of hydrochloric acid, probably by a series of operations or else by direct action on the hydrogen of the acid in presence of photochloride of iron, re-forms perchloride. The energy of this oxygen is the source of the current.—SIGMA.

[57026.]—**Problem.**—To this problem, as stated, no definite solution can be given. The quantity of water required must depend on the relative amounts of the two whiskeys in the mixture; but these are not given, nor any data from which they could be deduced. If these relative proportions are known, the problem may be solved without the aid of algebra. Assuming that equal quantities of the two whiskeys are mixed, the value of that mixture would be $\frac{16 + 19}{2}$, or 17s. 6d. per gallon. If the mixture be now diluted with water until its price is reduced to 12s. per gallon, the proportion of water added will be equivalent to the difference between the two rates divided by 12— $\frac{5·5}{12}$ or $\frac{11}{24}$ of a gallon of water to each gallon of the mixed spirits. Applying these data to the 51 gallons stated to be the final result, a simple rule-of-three calculation shows that these 51 gallons consist of—

| Gals. | |
|---|---|
| $16\frac{1}{35}$ | of water, |
| $17\frac{17}{35}$ | whiskey at 16s., |
| $17\frac{17}{35}$ | do. 19s., |
| 51 | mixture at 12. |

—W. HARDIE, Joppa.

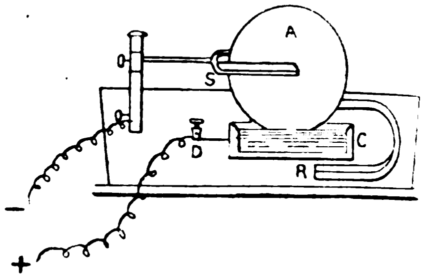
[57028.]—**Stamping in Relief.**—Many thanks to "Os" for his kind information, and would he (or others) kindly give the details of the process, whether by press or hammer? I have been put off over and over again till seven valuable weeks have been wasted before I could get hold of a few gross tickets, and to save such loss and annoyance in the future, I wish to know the most economical way in which I could get out my own tickets readily as wanted. I have the die, and am offered the "counterpart" for 3s. 6d. What are the counterparts composed of? And is this as cheap as I could make one for from the die? I suppose, whether struck up in a press or by hammer, something of the kind would be needed to sink the plate into the letters? What kind and strength of brass would be suitable, and what should be about the cost of press or other needed appliances? And would they do for stamping stationery in relief and colours? I suppose a separate die would be required? Can the tickets be stamped and cut out of the sheet at one operation or not? I noticed on some of the first tickets received some reddish fluid. What may it be, and for what purpose, and how is the lacquering or finishing done? A rough sketch of the most suitable appliances would greatly oblige.—A WOULD-BE STAMPER.

[57033.]—**Refining Gold.**—Dissolve alloy containing gold in a mixture of hydrochloric and nitric acids. The chlorine of the hydrogen chloride unites with the gold, forming gold trichloride ($AuCl_3$), which is soluble in water. To a solution of this add a small quantity of ferrous sulphate ($F_2SO_4$). A brown precipitate of very finely-divided gold is formed. Then filter, wash, and evaporate to dryness, leaving pure gold.—H. L. C.

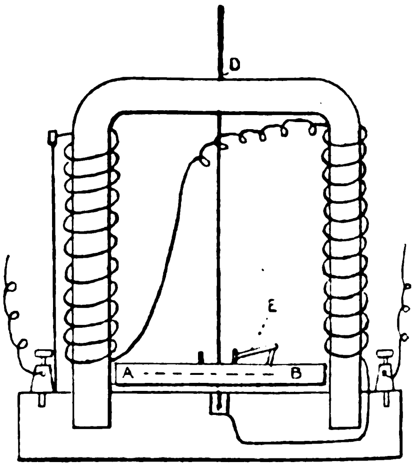
[57039.]—**Firing Mines.**—Get Dyer's book "On the Induction Coil." You will find in it various ways of firing mines.—THOS. H. HALL.

[57039.]—**Firing Mines.**—The best way to do this is with fuses. A cylindrical case of cardboard or other suitable material is filled with guncotton, and the wires pass through one end and are bored for a short distance and joined with a fine piece of platinum wire. The current passing through this fuses it and ignites the guncotton. The India-rubber, Guttapercha, and Telegraph Works Co. sell a constant battery for mining and blasting purposes. I do not know what it is like, but daresay it would satisfy the querist's requirements.—BUNSEN.

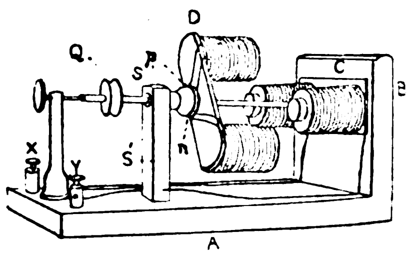
[57040.]—**Voltaic.**—One of the simplest means of showing motion produced by electricity is by the apparatus known as Barlow's wheel: A is a wheel of copper, movable on a stirrup, S. The edge of wheel dips into a cup of mercury, C. A powerful horseshoe magnet, R, is placed so that the wheel is exactly between the poles. The current enters at D, and passes to the mercury cup, it ascends the wheel to the stirrup, and from this back to the battery. The lines of force due to the magnet are at the point where the wheel dips into the mercury, perpendicular to the plane of the wheel, and consequently perpendicular to the radius by which the current ascends. Hence the rotation of the wheel.—BOBADIL.



[57040.]—**Voltaic.**—I send you a sketch of a small motor, which I think would answer your purpose. An electro-magnet, the legs of which are fixed into a base board. A soft iron armature, A B, fixed on a spindle, one end of which passes into a metal cup in the base, and the other end through the bent part of the electro-magnet at D. Two pins are fixed into the armature, against which pins a spring (E) is made to press alternately. The connections may be easily seen in the sketch. I should advise "Pith Ball" to put about four layers of No. 20 c.-c. wire on the magnet. If this will not suit, and the querist will let me know, I can give him descriptions of more complicated instruments.—ACCUMULATOR.



[57040]. — **Voltaic (Motor).** — Perhaps the simplest form of electro-motor which an amateur can make, to illustrate this special effect, is one consisting in two electro-magnets; one being fixed while the other is free to move, being supported by a spindle running between centres. The wires, which are coiled round the movable electro-magnet terminate in two semicircular pieces of brass, which are insulated from each other, and from the central spindle, which they encircle. Against these two half-rings of brass, press two springs of this sheet



brass, one of which is connected to a binding screw that places the motor contact with one pole of the battery; while the other spring joins the movable electro-magnet with one of the ends of the wires which surrounds the fixed electro-magnet. The other end of the wire, from the fixed electro-magnet, goes to the other binding screw, and from thence makes contact with the other pole of the battery. In the annexed cut, A is a wooden base, about 5in. long by 2in. wide, B a wooden upright, about 2¼in. high by 4in. wide. To this latter is screwed the fixed electro-magnet C, made of two short pieces of soft iron rod, soldered down to a piece of iron hooping. The dimensions of these pieces of iron are 1¼in. long by ¼in. diameter. The movable electro-magnet, D, is made in precisely the same manner, and is of the same dimension. Both are wound with about three layers of No. 20 cotton-covered copper wire. The wires from D are connected respectively to the two half-rings, which form the split collar, *p*, *n*, against which press the two springs, S, S′. The spindle rests on centres, and has a pulley, Q, by which the motion can be transmitted where desired. The current from the battery enters (say) by the binder X, traverses the coils of the fixed magnet, leaves them near B, and passes up the spring S′, enters the movable magnet, and causes it to be attracted by the fixed magnet. It comes out by the wire P, and, descending by the spring S, returns to the battery by the binder Y. For the motor to work properly, the springs and split collar must be so arranged that the springs find themselves pressing on the brass portion of the split rings at all times, *except* when the poles of the movable magnets are exactly opposite the fixed magnets; in which case they must be resting on the splits, or, in other words, contact must cease.—S. BOTTONE.

[57042.] — **Spark Coil.** — I should advise "E. B. F." to get Dyer's book "On the Induction Coil," which will give you a large number of experiments other than "spark through vacuum tubes."—THOS. H. HALL.

[57042.]—**Spark Coil.**—As "Bobadil" has kindly offered to help me, I may say my coil gives a ⅛in. spark. I would be glad to know what experiments I can perform with it, and if there are experiments of much interest which are better shown with a larger coil, I will get one. But does a larger coil require a larger battery.—SPARK.

[57043.]—**Spectroscope.**—If "Jolly Miller's" spectroscope were powerful enough, and its slit fine enough, it would show the thickest of the three lines double; it alone is the sodium or D-line. The two conspicuous, but much thinner, lines, close to it, on the red side of the spectrum are the chief lines of the rain-band. They are not always visible, and being, when present, always strongest in the light coming from the horizon, they thus betray their atmospheric origin, the light from that quarter having traversed a much greater thickness of air, and also denser air than that coming from the zenith.—W. HARDIE, Joppa.

[57048.]—**Hardening Dividers.**—Heat to a red heat, quench, rub clean with emery cloth, and hold over the flame of a spirit lamp till it shows blue, then quench.—THOS. H. HALL.

[57050.]—**Dynamo Construction.**—To W. H. EAVES, COVENTRY.—For 50 volts and 15 ampères make your A. 8in. by 4in. and wind with one layer of No. 16. This size is the same diameter, but half the length, of the 30-light armature (letter No. 24267), to which letter you can refer for size and thickness of discs, &c. The next letter on the 30-light dynamo will appear shortly, and from the instructions contained therein you will see the size of F. M., &c., that you require.—W. H. EAVES, Coventry.

[57052.]—**Weight and Stress of Beam.**—

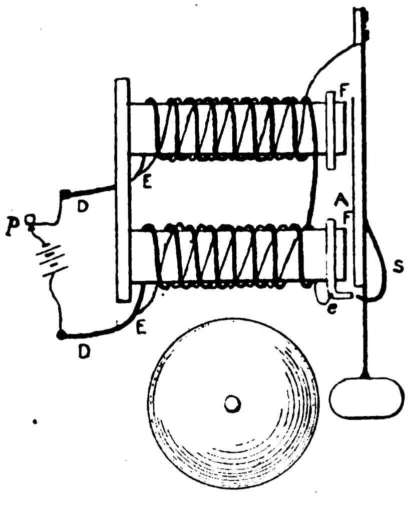
$$S = \frac{2 \times 100 \times 73}{100} = \frac{68600}{100} = 686\text{lb.},$$

with $\frac{1}{40}$″ deflection.—THOS. H. HALL.

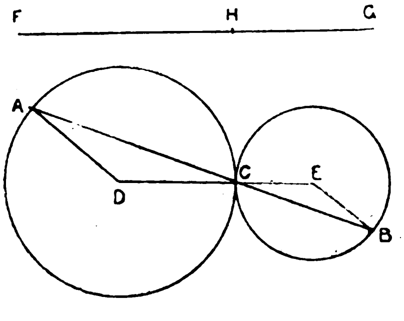
[57056.]—**Problem.**—If G. Fryer will reflect for a moment, he will be able to answer his own query. The number of men now living cannot exceed that of all those born during the last 70 years—seeing that the average duration of life is much under 70 years—while "the dead" comprise all who have died since man first appeared upon the earth; it is not, therefore, 50 per cent. in favour of the dead, but their number is manifold that of the living.—GAMMA SIGMA.

[57055.] — **Electric Bells in Series.** — In answer to the questions of your correspondents and their remarks, which evidently refer to the Jolin patent system of electric bells, we, as owners and sole manufacturers of the above, beg to say that we shall be most happy to give any of your readers full information if they will write to us on the subject, as the description would take up too much of your valuable space. We find no difficulty about the quality of iron: your correspondent probably does not know that soft wrought-iron is always used by all good makers of bells for the cores. Instead of complications, our bell is simpler than an ordinary one, and much cheaper to make; perhaps it is not generally known that it costs no more to wind two wires than one in the way coils are now wound by machinery. Will your correspondent explain what he means by "counter currents."—P. JOLIN AND Co., Electricians, Bristol.

[57055.]—**Jolin's Electric Bell.**—When the push P is pressed, a current flows through the coil D, magnetising the cores F, which attract the armature A; but on the spring S touching the contact *e*, the circuit in E is completeted, the magnetism of the cores destroyed, and armature released.—FRA. BROADBENT, Hammersmith.



[57058.]—**Science Examination, May, 1885—Mathematics, Stage II.**—Let D and E be the centres of the given circles which touch at C. Let F G be the given straight, less than the sum of the diameters of the circles. It is required to draw through the point C a line A B equal to F G. Divide F G in H so, that F G shall be to H G in the same ratio as D C to C E (Euc. VI. 10). From C as centre, and radius F H, describe a circle cutting the circle A C in A, and from C as centre and radius H G describe a circle cutting the circle C B in B. Join C A, C B. Also join D A and E B. Then since A C : C B : : D C : CE therefore A C : C D : : C B : C E; and since C D = D A, and C E = B E, therefore A C : A D : : C B : B E. Hence the triangles A C D, B C E are equiangular (Euc. VI. 5); and, therefore, the angle A C D is equal to the angle E C B. And since D C and C E are in one straight line, therefore A C and C B are in one straight line, and from the construction, A B is equal to F G, and it is drawn through the point C as required.—J. E. GORE.



[57059.] — **Power.** — The power or potential energy necessary to raise the weight up stairs at an angle of 60° would equal $\frac{\sqrt{3}}{2} \times 110 \times 22$

$$= 1210\sqrt{3}$$
$$= 2093{\cdot}3 \text{ foot-pounds.}$$

If chain pulleys were used, the power would equal (when they are as 1 to 24) 24 × 110ft.lb. = 2640ft.lb. I have not calculated what the friction would be; but as the number of pulleys is not given, it will suffice to say that the whole power would increase as the number and weights of the pulleys.—NESTER.

[57063.]—**Specific Heat.**—Suppose $\theta°$ is the temperature of the mixture, we have the following equation:—$5 \times 79 + 5\theta = 25\ (50 - \theta)$, where 79 is the latent heat of liquefaction of snow. Solving we find $\theta$ is equal to 11·83° Cent.—H. L. C.

[57063.]—**Specific Heat.**—Let $x$ equal resultant temperature, then the temperature of the water falls $(30-x)$ degrees, and in doing so gives out $(30-x)$ 25 grm. units; the temperature of the snow rises $x$ degrees, and in doing so absorbs $(79{\cdot}4 + x)$ 5 grm. units of heat; but the heat absorbed equals that given out, therefore—

$$(79{\cdot}4 + x)\ 5 = (30-x)\ 25$$
$$397 + 5\ x = 750 - 25\ x$$
$$30\ x = 353$$
$$x = \frac{353}{30}$$
$$= 11{\cdot}76°$$

This may be verified by experiment.—DAVID STEPHEN.

[57064.]—**Bisulphite (not Bisulphide) of Silver — Roseleur's Solution for Simple Silvering.**—Dissolve 4 parts common washing soda in 5 parts distilled water, and place solution in a deep narrow vessel containing about ¼in. depth of mercury; stand a long glass tube in the bottle, its lower end, of course, resting in the mercury, and pass through the tube sulphuretted hydrogen gas, which make in the usual way in a Woulff's bottle, sulphide of iron, and dilute sulphuric acid, and continue to pass the gas through the soda solution till it is found to redden blue litmus paper. Stop the flow of gas as soon as this is observed, as the solution must not be allowed to become decidedly acid. The soda solution must now be carefully poured off, leaving the sediment, and after standing 24 hours again tested for acidity, and separated from the sediment, if any. If it still reddens blue litmus paper decidedly, put in a few more soda crystals, until the paper is only changed to violet. If it renders red litmus paper blue it is too alkaline, and more gas must be passed into it. When you have got your soda solution just right (bisulphite of soda), prepare your silver solution by dissolving any quantity of nitrate of silver in distilled water, and add by degrees to your first solution as long as the precipitate at first formed is dissolved. The moment you have a precipitate which refuses to dissolve add no more, as it would be simply waste. Now you have converted your bisulphate of soda solution into one of bisulphate of silver, and are ready to begin work. The solution is used cold and will produce the most beautiful coatings, light or heavy, according to the time of immersion, on almost anything, particularly brass, copper, and bronze, and will work for years. When the silver gets exhausted by continual wear, simply add more nitrate solution. For particularly important work it is wise to dip the goods, after cleaning and before plating, in a weak solution of nitrate of mercury. "Argent" will see, therefore, that the process is one of silvering by immersion. I do not know if it could be used for what I may call silvering by transfer, the method, of course, most used for barometer dials. However, the experiment might be easily made. If the result seemed satisfactory, I should certainly varnish it for security. I have received a postcard signed "Another Reader of the ENGLISH MECHANIC," requesting me in this place to reply to a few additional questions on silver-plating. I think it would have been better to have inserted his queries, or sent address, so I might have answered him by post. However, I may say, in reply, that I gave the hyposulphite solution in reply to query 56584 simply because it seemed of the kind the querist was seeking, and carefully guarded myself from recommending its adoption. I said it was fair—not good. In reply to a second query, the best method of (true) silvering on glass is, I believe, that of Boettger, which consists of two liquids—(*a*) Into 40oz. boiling water throw 48gr. Rochelle salt, and add gradually a solution of 1dr. of nitrate silver in 1oz. water. Boil ten minutes, and filter when cold. (*b*) Dissolve 1oz. nitrate silver in 1oz. water, and add liquid ammonia till the precipitated oxide is just redissolved. Then add 12oz. water, and filter. A mixture of equal volumes of these two liquids coats glass (Boettger says) in the course of ten minutes with a bright shining layer of silver. I believe, however, the time taken depends on the temperature of the solutions, the above speed being the result of a temp. of 30° C. It is, however, safer to use the solution cold, although the action is not so rapid. In reply to the next question, it is quite possible to deposit platinum, but the result is rarely satisfactory.—PERCY W. STANLEY, 119, Manchester-road, Poplar, E.

[57066.]—**Reducing the amount of Lime in Chalk Water.**—"C. H. D." can obtain a copy of the specification of Clark's patent process at the Patent Office, Southampton-buildings, Chancery-lane, London. The so-called "chalk" is held in solution by carbonic acid in the water. By adding quicklime to this water, the excess of carbonic acid attracts the quicklime, and both the new compound and that previously held in solution are deposited in the form of very finely-divided chalk, which has to be removed by filtration through several layers of stout canvas. The apparatus requires frequent, almost daily attention; but is very effective, and where several householders combine, the cost is not very onerous.—GAMMA SIGMA.

[57068.] — **Dynamo.** — To W. H. EAVES, COVENTRY.—By winding your A. with a single layer of No. 18 you will get about 35 volts and 8 ampères, which current will light four 20 c.-p. lamps. Make your magnets of the best wrought-iron, and wind them with from 20 to 25lb. of No. 18. My second letter on the 30-light dynamo is partly written, and will be in the Editor's hands in a fortnight. I am very sorry I have not been able to send it before, it having been delayed from time to time by pressure of business.—W. H. Eaves, Coventry.

[57070.]—**Telephones.**—I think I can help the querist with his instruments. No. 38 s.c. wire is generally used, but 40 would do, I should think. Of course less 40 would be required than 38. I think about 280ft. would be sufficient. No battery is required with these: they are simply connected. They will not speak far. What size was the 1,000ft. of wire used in the experiment?—Bunsen.

[57073.]—**From Mr. Rogers.**—If "Accumulator" will publish his address, I will send him a working sketch of the ammeter I described, which can be moved about or carried in the pocket without injury.—F. M. Rogers.

[57075.]—**Parchment Paper.**—This has been given many times in back numbers. Dip unsized paper into dilute sulphuric acid, and then into ammonia or clean water.—Onbr. Juthos.

[57075.]—**Parchment Paper.**—I suppose you mean vegetable parchment, such as is sold for the purpose you require it. This is made by passing white blotting paper through a bath of sulphuric acid of about 140° Twaddell, and afterwards well washing in pure water. The exact strength of the bath is only to be obtained by experiment, and it will dissolve the blotting paper if not right.—Quod Dixi Dixi.

[57079.]—**Windway.**—I cannot help your correspondent "A.B.C." for two reasons: First, because I don't know how to convert a cavity-board into an arrangement suitable for the paper "music"; and, secondly, because I will not assist anyone to spoil a good piece of work in producing a botch. If your correspondent wants a 3½ octave automatic instrument, surely he can make a board to carry the reeds without spoiling a two-row American organ board. It would be an easy matter if he were going to use the barrel arrangement, with levers to depress the pallets.—Organon.

[57079.]—**Windway.**—If "A. B. C." intends to adopt two sets of reeds instead of one, I should advise him to adopt the lever principle, with pallets, &c. If "A. B. C." goes beyond the compass of three chromatic octaves (that is, 37 notes), I am afraid his instrument will be considered clumsy in the eyes of some people. It is only a question (at least, in my opinion) whether the querist wants music from his proposed instrument, or a very limited number of tunes, with harmony equally limited in its variety of effect.—G. Fryer.

[57080.]—**Siphon.**—The failure of your siphon is probably due to an accumulation of air in the long limb, either sucked in through some leak in the pipe or given off from the water. You must surely mean that the end of the leg is 36ft. below, not 31ft. above the bottom of the well.—W. A. S.

[57080.]—**Siphon.**—In "Surveyor's" data, some error has surely crept in. The last statement should read, I imagine, 36ft. below bottom of well, instead of "31ft. above bottom of well." In all probability accumulation of air is the cause of stoppage. Remedy, as the air in the pipes has always a tendency to reach the highest point, a suction pump should be put on the highest part of the siphon, and blow-off valves at the top of all upward curves in the progress of the pipe.—B.Sc., Plymouth.

[57080.]—**Siphon.**—Your siphon would be certain to cease working in a very short time, because air is certain to accumulate at the top of the summit level. The water in all siphons gives off air under the conditions set up, and the partial and subsequent entire cessation of the flow is due to the air accumulations. These first reduce the size of the stream flowing over the summit level, thus being equivalent to reducing the size of the bore, and as soon as the globule of air attains a diameter equal to the bore of the pipe the flow ceases entirely. On a past occasion, where a large siphon was used to clear the water out of a railway tunnel, the siphon invariably ceased working in a few hours from accumulation of air. As the siphon cost a tithe of a pumping engine, we tried several plans, and finally managed to get on an appliance to extract the air as it accumulated.—Invicta.

[57080.]—**Siphon.**—There appears to be a misprint in the query, as the outlet is stated to be 31ft. *above* the bottom of the well; under which conditions, of course, the siphon would not commence to work. From the data given, it would appear to be 36ft. below this point. The failure of the siphon is most likely due to air or fixed gas (probably carbonic acid), held in suspension in very minute quantities in the well water. When the ball-cock is closed and water in the pipe at rest, this air or gas under the influence of pressure in the pipes, possibly assisted by change of temperature, would tend to disengage itself from the water, and travel in very minute bubbles to the summit of the pipes, where a small accumulation would stop the action of the siphon. If, instead of closing the ball-cock the siphon were allowed to run, it would probably continue to do so for an indefinite time, the water carrying away with it the contained air or gas. The writer would be interested to learn whether this suggestion is successful.—R. R. N.

[57081.]—**Watch-Maker's Bow.**—To make a good bow there is nothing like whalebone. The best way is to got hold of an old carriage umbrella, which will afford enough for two or three dozen. For watch-work the bow should be scarcely a foot long, and horsehair should be used. It is a great mistake to have the bow too stout, and, consequently, too much tension. When not in use, it should be nearly straight, and when on the ferrule only sufficiently tight to carry the work safely, as there is no resistance when pushing the bow from you. The knack of easing the graver off the work in this back stroke is soon acquired by practice.—Escapement.

[57083.]—**Freemasonry.**—If "Z." looks upon Freemasonry as a mere benefit society, the less he has to do with it the better for the Craft. If he becomes a Mason, he should do so, hoping to do good, and receive nothing in return. The expense incurred depends upon the lodge he joins. It need not cost him more than five and a half guineas, inclusive of regalia. If "Z." is initiated, and yet receives no pecuniary benefit from the charities, I imagine he will find himself more than adequately rewarded both morally and socially; always provided he enters Freemasonry in a right spirit.—P.M., P.G.C.

[57084.] — **Shunt Dynamo.**—To Mr. Bottone or Others.—In order that there should be a current, a complete go and return path must be open for the electricity to flow along. When the brushes are not pressing against the commutator, the road is not open, and no current passes, the fields are not magnetised, and apparently little or nothing takes place. The origin of the current lies in the trifling residual magnetism of the iron cores. This magnetism derives it being, if the cores are really very soft, from the magnetism induced by the earth. In ordinary cases, a small amount of magnetism is set up in these cores either by percussion during manufacture, or by the use of the battery. However produced, this magnetism is always very small in amount, and would give but little effect if the current set up in the armature on rotation were led directly to the outer circuit. But, in the dynamo, this infinitesimal current is led round the cores of the field magnets, and, in circulating round them, sets up a higher degree of magnetism, which, if the motion is kept up, sets up in its turn a higher electromotive force, and so on, until the limit of saturation is reached. The brushes have nothing to do with the generation of the current: they are the sluice gates, which, when in proper position, allow the current to flow. See my book on "The Dynamo."—S. Bottone.

[57088.] — **Emigration.** — In reply to "An Anxious One," the writer has spent some nine or ten years in Canada and the United States, mainly as wood-carver and cabinet-maker, and is pleased to give the benefit of his experience. He by far prefers the States to Canada, and, if refinement and more home-like circumstances be a consideration, he prefers the Eastern (say Virginia, for instance) to the Western; but if able to "rough it," and money-making be the object, he would recommend some of the younger States or Territories. As to what country will offer the best opening, I consider it a question impossible to answer. It is like asking, Is there any opening for a cabinet-maker in all Europe? No one can say without a vast deal of travelling over the whole Continent. The writer would recommend "Anxious One" to decide as to *where* he will go on other grounds—climatic, for instance, &c.—and then make the best of it. He would also advise some time spent as a journeyman in different parts of the country till he has a fair insight into their ways of doing things, and also giving him time to decide where he would like to locate. The Americans are very go-ahead, and make large use of machinery, which of course is hard on hand labour, except in some small country towns and villages, where a fair workman might do well. The best part of the writer's experience there perhaps was while putting up good furniture at the country gentry's own houses, working on the premises and boarding with the family.—Virginia.

[57092.]—**Ginger-beer Plant.**—I don't know the botanical order to which this plant belongs, but I believe it is a fungus of some sort. Ginger-beer is made with it by simply putting it into a bottle and filling the bottle up with bits of whole ginger and sugar to taste. It must be kept lightly corked; when it blows the cork out it is ready to drink. It must not be left more than a day in the bottle with the plant, or it turns bitter. Use white loaf sugar, not brown, which makes a most abominable concoction. I have drank quantities of ginger-beer made by the plant, and I am still sufficiently vigorous to answer this query. The plant grows enormously (that is the grains increase in number), and has to be separated into more bottles at intervals, as it doesn't do to have too much in one bottle—R. A. R. Bennett, Walton Manor Lodge, Oxford.

[57092.]—**Ginger-beer Plant.**—This plant belongs to the genus Scitamineæ or Zingiberaceæ. Gingerbeer is generally made from the common ginger (*Z. officinale*), and is distinguished as the narrow-leaved ginger, which is largely cultivated in the East Indies. The root stock—the ginger of commerce—is of the thickness of a man's finger, knotty, fibrous, and fleshy when fresh. The stems it sends up are reed-like, the leaves being linear-lanceolate, and smooth. The flowers are produced on short leafless stems, and are of a whitish colour. Gingerbeer is an effervescing drink made by fermenting ginger, sugar, and some other ingredients, and bottling before the fermentation is completed. Ginger in all its preparations is extremely safe and harmless for the palate, and is occasionally used as a domestic remedy, in the shape of ginger-tea, candied ginger, &c.—Nester.

[57098.]—**Warehouse Lift.**—This question is rather vague, as the speed at which load is to be lifted governs the cost; 5cwt. lifted 60ft. per minute = 112 × 5 × 60 = 33,600 foot-pounds, or just over one horse-power. To drive a lift at this speed, and overcome friction, &c., about 1¼ horse-power is needed. If "W. J. D." will say what speed will suit him, I will send a sketch, and give rough estimate of cost. Is the lift to work direct through floor, or outside by means of a jib?—F. M. Rogers.

[57101.]—**Spectra.**—It seems to me that all you want to know is the names of the substances which will produce various-coloured lines in the spectroscope. Put the instrument facing the flame of a spirit-lamp or Bunsen burner, and get someone to shake into the flame some strontium nitrate; this will give a brilliant scarlet line. Calcium nitrate gives a brick-dust line; barium nitrate will give a green line; copper chloride gives a blue line, and so on. You won't get single lines unless you use the chemicals; for whatever substance you burn (as paper, &c.), everything is so strongly impregnated with sodium that you will always get the yellow line.—R. A. R. Bennett.

[57102.]—**Air and Fuel.**—"Vulcan" should remember that although the air presses on all bodies with a pressure of between 14lb. and 15lb. to the square inch, yet the pressure is equal in every part alike. Now, to take his own illustration, say, in the case of a factory steam boiler, the pressure on the column of air issuing from the chimney is the same as that pressing on the underside of the fuel on the grate bars. I am in this eliminating the slight difference in actual fact due to the conditions of draught. Combustion being entirely the outcome of a liberal supply of oxygen gas by forcing in air, either by the aid of a bellows, or the assistance of a tall chimney stack, the oxygen contained in the air is brought into contact in larger volume with the fuel, and therefore the more rapid combustion. Supposing it were possible that the top of a chimney discharged the products of combustion into a vacuum the air pressure of, say, 15lb. would rush in so fast that the supply of oxygen would be so abundant that no grate bars would remain unfused many seconds. One more illustration. A copper ball, such as is used in every water cistern, is so thin that 2lb. or 3lb. pressure on the outside in excess of that inside would collapse it. But it never does collapse, because the interior being filled with air, an equlibrium is set up. The same state of things exist with your smith's fire when the bellows are not in motion.—INVICTA.

[57104.]—**Actuarial.**—Smart's Tables give £5 8s. 8·9d. and £5 15s. 7·9d. as the annuities for 30 years (half-yearly payments), which £100 will purchase at 3½ and 4 per cent. respectively.—BETA.

[57104.]—**Actuarial.**—To make the calculations asked for by "Annuitant" would only be wasting time, and of no general benefit. He should call on insurance companies who make annuities a speciality and ask for their tables.—B.Sc., Plymouth.

[57106.]—**Galvanised Iron Pipes.**—Zinc is dissolved by pure water, and is attacked by water containing carbonic acid. The French Government have for some time past prohibited the use of galvanised tanks in their navy. Zinc carbonate is a white, tasteless powder, and is insoluble in water. It is sometimes prescribed as a tonic, in doses of from 2 to 10 grains, and would be injurious if it exists to any great extent. The only remedy is, I fancy, replacing the pipes with others of lead. In this case a carbonate would be formed, which would prevent the water from further contamination. If, however, the water be soft, a lead pipe would be oxidised by it, and the water would be highly poisonous. I would advise that some of the white substance and the water be submitted to a competent chemist.—F. M. ROGERS.

[57107.]—**Developing Formulæ.**—(1) Liquids should be measured with a glass measure, not weighed, although practically I don't suppose it would make any difference. (2) All developers do *not* require the same exposure. The sodic sulphite one has a far wider range than either the ammonia pyro or the iron developers.—B.Sc, Plymouth.

[57107.]—**Developing Formulæ.**—An ounce of water weighs exactly 1oz., and therefore your formula would be right, if you weighed the water—albeit it would be considerably less trouble to use a measure, if possible. But water is the standard of fluid measures and weights, so remember that your dodge won't answer for anything but water; some fluids, such as sulphuric acid, being very considerably heavier. The exposures required are by no means the same for all developers, some requiring less and some requiring more. The best plan is to stick to the one you find answers best—sodic sulphite for example.—R. A. R. BENNETT, Oxford.

[57108.]—**Home Trainer for Bicyclists.**—There is an engraving of one of these in Goy's Athletic Catalogue, which will, no doubt, give "Mechanic" a good idea.—ONER. JUTHOS.

[57108.]—**Home Trainer.**—Far better than any mere description is the printed description of the bicycle stand and home trainer combined in one which I think is made by Messrs. Singer and Co., of Coventry. It is a casting with two large turned and grooved rollers. On these the driving-wheel runs. Two series of stay rods hold the handle bars so that the machine is held vertically.—INVICTA.

[57109.]—**Focus of O.G.**—By all means have your o.g. 50in. focus rather than 40. The advantage in the longer focus is by no means to be despised. Do you wish to correspond with me outside these pages? If you advertise your address I will freely and gladly give you any information in my power, by letter if you prefer that. Ask freely and frankly, and as freely and frankly will you be replied to.—INVICTA.

[57110.]—**Dynamo for Electro-Plating.**—Yes; it is perfectly practicable for an amateur to make a plating dynamo. No battery is known that does not require much looking after or replenishing to do the work you need.—S. BOTTONE.

[57110.]—**Dynamo for Electro-plating.**—It is quite practicable to use a small dynamo for electro-plating, provided the machine is wound to give out a quantity current. This is accomplished by using thicker sizes of wire on armature and field-magnets than would be used were the dynamo for the electric light, while the current must, of course, be continuous. Where batteries are employed, they are usually Smee or Daniell cells, either used singly, or connected for quantity or intensity—the arrangement depending on the nature of the work. In every case, however, the article to be plated is connected to the negative pole in the depositing vat, and the anode (silver, gold, or copper, as the case may be), is connected to the positive pole.—BOBADIL.

[57112.]—**Wet-Plate Photography.**—Get "The Principles and Practice of Photography," by Jabez Hughes, price 1s., from Simpkin, Marshall, and Co., 4, Stationers' Hall-court, E.C. I hardly know which process is easiest, but the dry is most advantageous for many reasons too numerous to mention here, which I will gladly name if you like in "E. M.," or by post.—W. J. R.

[57112.]—**Wet-plate Photography.**—1, The treatise by Mr. Dawson, editor of the *British Journal of Photography*, price 1s., published by Mason, 186, Sauchiehall-street, Glasgow, gives full instructions; 2, dry plates for portrait work are far the easiest for an amateur to master; 3, dry plates will not keep any length of time, but I have taken good photographs with plates a year old.—B.Sc., Plymouth.

[57112.]—**Wet-Plate Photography.**—Obtain Jabez Hughes's "Principles and Practice of Photography," price 1s., or Stanley's "Photography Made Easy," price 9d. Both are highly practical. From the last, which was sent me abroad, I practically learnt the wet-plate process. Hughes's 1s. book is equally good, but more extended. I can safely recommend you either as reliable and clear. Wet plates are easiest, in my opinion, for an amateur. But when the manipulation is perfect for speed, you would want to use dry plates. When you are ready to adopt them, I can from personal experience recommend you good hand-books on dry-plate manipulation.—INVICTA.

[57112.]—**Wet-Plate Photography.**—One of the best books published now is "Hardwich's Photography," but I am not sure about the price, probably about 3s. 6d. from its size. Before the dry-plate process was perfected I did not attempt to take photos, being appalled at the sight of so much labour; but when the dry-plate process came out, I went at it tooth and nail. I think there is not much doubt as to which is the easiest, and the best also, to my mind. Wet plates are necessary for some kinds of work, but not the sort "Jay Why" is likely to come across. Hardly any (one might almost say, no) professionals use wet plates now. The dry plates will keep any length of time under favourable conditions, that is, they must not be kept in a damp place—the dryer the better.—R. A. R. BENNETT, Walton Manor-lodge, Oxford.

[57113.]—**Photography.**—The fault lies not in Fry's plates or the developer, but with the individual who is using them. State carefully your mode of procedure, and I will help you and put you right. "Show me your faults, and I will tell your successes."—S. BOTTONE.

[57113.]—**Photography.**—Try Wratten's "Slow," or, if they are too expensive, the "Britannia." The best developer for amateurs is the Standard of the New York Society, as modified by Mr. Beach; his formula is given in late numbers of the *Amateur Photographer*.—B.Sc., Plymouth.

[57113.]—**Photography.**—Try Miall's plates and Swan's developer, viz.:—(1) Pyro, 3gr.; water, 1oz., at time of using. Stock Solution.—(2) Liq. ammoniæ, ½dr.; bromide of ammonium, ½dr.; water, 5oz. Use equal parts of each. If the picture comes out too slow, add more of No. 2. Soak your plate before development.—W. J. R.

[57113.]—**Photography.**—I have "tried various plates and developers," and the very best plates that I have yet come across are "Marion's Britannia plates" (22 and 23, Soho-square). There is no doubt that first-rate results can be obtained from Fry's, when you know how to get them; but in my opinion Marion's are more certain in the hands of an amateur, so much so that I use them now to the exclusion of all other makers, and several friends to whom I have recommended them say the same. Use sodio-sulphite developer, it answers much best with these.—R. A. R. BENNETT, Walton Manor-lodge, Oxford.

[57113.]—**Photography.**—It is very probable that the curious and unexpected results you have obtained arise from variations in the sodic sulphite you employ. Of all the chemicals employed in the photographer's laboratory none is so uncertain in its composition. In the commercial article imported from Germany there is usually only about 50 per cent. of true sulphite of soda, the balance being an uncertain mixture of carbonate, sulphate, hyposulphite, and other impurities. It must, however, be remembered that pure sulphite of soda is itself strongly alkaline to litmus paper, and it is usual to neutralise this by the careful addition of sulphurous acid. However, as this is troublesome to prepare, and difficult to keep, it is well to use crystallised acid sulphite of potassium for neutralising the sodic sulphite instead, as it is quite permanent, and answers just as well. These salts may be obtained from A. Boake and Co., for whose address I refer you to the sixpenny sale column this week.—W. G.

[57113.]—**Wet-Plate Photography.**—All photographic dealers keep works on collodion picture taking. These can be had at about 6d. each. Dry plate is easier to learn for amateurs—mechanically easier—but the wet plate gives a more thorough knowledge of the chemistry of photography. Dry plates will keep for years.—S. BOTTONE.

[57115.]—**Faulty Telephone.**—See my reply to 57070.—S. BOTTONE.

[57121.]—**Mountain Snow.**—"Ignorant" must remember that the temperature of the air decreases 1° Fahr. for every 300ft. or 350ft. of altitude. Hence the temperature at the top of a high mountain would not contain sufficient heat to melt snow. The region of perpetual snow, the lower edge of which is called the *snow line*, is on account of the intense cold at the sea level at the Poles; but at the Equator, on account of the heat, it is 1,600ft. above the level of the sea; and in the intermediate spaces the snow-line will be correspondingly higher or lower as it is nearer the Equator or Poles.—NESTER.

## UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

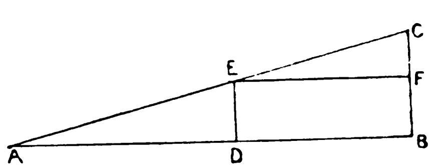
## QUERIES.

[57122.]—**Problem.**—In the right-angled triangle, A B C, D E is parallel to B C, and E F to A B; A C, D E, and E F are given to find A B. A pure trigonometrical formula required; "trial and error" not allowed; perhaps, however, more than one formula may be required. In practical terms these may be stated thus: A C a ladder 50ft. long; D E F B a porch 10ft. wide and 20ft. high, the ladder touches the edge of the porch. To what height will the ladder reach on the wall A B?—R.



[57123.]—**Hand Fire Extinguishers.**—I have been much puzzled to find out what is used to generate carbonic acid gas, in order to create the pressure which expels water from the above. Having no means of testing the substance myself, I should be much obliged if some kind friend would give the information.—H. L. C.

[57124.]—**Lifting Bar.**—In lifting horizontally with my hand, a bar of iron which lies upon the ground, weighing, say, 5lb. to a height of 4ft. I perform the work easily by taking hold of the bar by its middle, thereby doing 20ft.-lb. of work. If I lift the bar by taking hold of it at its end, it requires much more strength to lift it; yet, in this case, I do not gain time, space, leverage, or work done. How is this? And is not the hand a lever, fulcrum, power, and weight in the matter, and what of the bar?—NORFOLK.

[57125.]—**Photo Scrap Book.**—What is the best way of keeping photographic views of different sizes? If stuck in an album the leaves generally crumple and look untidy, besides, an album has the disadvantage of being at the disposal of one, or at the most, two persons only at one time. I thought of mounting them on cards of uniform size, and having a case made to fit. If this is the best plan, what size cards should be used, and of what thickness, and what is the best gum to use for sticking the photos on?—F. A. R.

[57126.]—**Obach's Galvanometer.**—What is the form of the Tangent galvanometer? Is Obach the inventor, or an instrument maker, or both?—B. S. T.

[57127.]—**Lactic Acid in Whey or Milk.**—Will any reader kindly inform me of any instrument whereby the presence of lactic acid in whey (or milk) can be determined, and of the various degrees as the acidity advances?—NO SIG.

[57128.]—**Storage Battery.**—Will some of our readers kindly give full particulars how to make the above suitable for lighting a 5-c.p. incandescent lamp for 10 hours, the battery to take up as little room as possible? I have never either seen one or read particulars of how they are made, so that as plain an explanation as possible will be esteemed a favour.—WEEDNA.

[57129.]—**Steam-Engine for Farm Work.**—On a farm there is a threshing and churning machine worked by the ordinary horse-gear. A pony can either thresh or churn quite easily, pulling at the horse-shaft, 9ft. 6in. from the centre, and going round 2½ times per minute. The churn has about 72 revolutions per minute, produced by intermediate gearing-wheels, and the thresher about 400, driven by a belt from a large pulley on the wall-box shaft. What I want to know is, the diameter, length of stroke, and revolutions per minute of a steam-engine (horizontal) that would both thresh and churn at the same time, with a boiler pressure of 35lb. per sq. in.; also size of vertical boiler with cross tubes that would be required. Of course, I would use intermediate gearing or pulleys to bring up necessary speed of churn and thresher. Would a steam-engine be cheaper to work than a gas-engine? I should have to make my own gas. I have a 7in. screw-cutting lathe, and could do a good deal at fitting up an engine.—YOUNG FARMER.

[57130.]—**Pump.**—I have water at the bottom of a field; I wish to get it to the top, a distance of 450 yards with about 30ft. rise.—FARMER.

[57131.]—**Bidwell System.**—What is meant by running tramcars according to the Bidwell system?—X. Y. Z.

[57132.]—**Electro-Motor.**—Can any harm be done to a shunt-wound motor by suddenly reversing the direction of the current through it, when running at full speed, to act as a brake to stop its motion?—W. E. H.

[57133.]—**Removing Tin from Scrap.**—Would any brother reader tell me how to remove tin from scrap, and recover the tin? Full particulars will oblige.—M. F. K.

[57134.]—**Easton's Syrup.**—What is this, and for what diseases is it recommended?—TRINKLEID.

[57135.]—**Varnishing Fancy Woods.**—I have made a small box veneered with fancy woods, principally rosewood. It has been varnished with "carriage varnish," which has dried hard upon all the woods except the rosewood. Upon it I cannot get it to dry. The rosewood has been cleansed and revarnished several times, but always with the same result. It seems to emit a gum which prevents the varnish drying. Can any reader suggest a cure?—T. J. A.

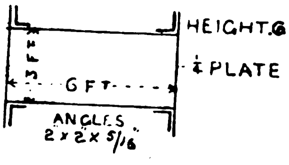
[57136.]—**Problem.**—Will any reader work the following? A cubic foot of water weighs 1,000 ounces avoirdupois; a pipe, whose bore is 3½ square inches, discharges 252lb. per minute. Find the velocity per hour of the issuing water.—JUDY.

[57137.]—**Reviving Ormolu Ornaments.**—Would some obliging correspondent put me in the way of cleaning and reviving some French ormolu, consisting of candlesticks, pen tray, &c.?—ORMOLU.

[57138.]—**Hair Monograms.**—I have some hair of a friend which I wish to put in a locket in the shape of a monogram. I shall be glad if any of my fellow readers of this valuable paper will oblige me with information how to do it myself, or as to the best place to get it done.—H. N.

[57139.]—**Amateur Modeller.**—Would anyone sympathise with me and tell me of something in the above way to be going on with until I find something more suitable for me in the "E. M.," as I find the articles just now appearing in the "Amateur Workshop" are rather beyond me? Will someone take compassion on me?—SIMPLETON.

[57140.]—**Safe Load.**—Will some correspondent please give rule for calculating safe load on a structure of this section? Also, what difference in calculation would it make if the casing were filled with water, supposing the bottom were closed?—S. B. BARD.



[57141.]—**Gas-Engine.**—To "INVICTA," "J. H.," AND OTHER PROFESSORS OF THE GAS-ENGINE.—I have had offered to me, and possess full working drawings of, a gas-engine, patented by a gentleman the name of Rodgerson. The article is of a very novel type indeed, and not being very versed in the merits of a gas-engine, I must ask the opinion of others. The arrangement is, a power cylinder and a charging cylinder, placed side by side, the products of combustion pass round a jacket in the charging cylinder, thereby heating the gas; the governor is placed so as to govern the gaseous charge immediately previous to its entering power cylinder, and after it has left charging cylinder. The novelty in the engine, however, is the mode of introducing the charge, and igniting it, the processes being by means of slots in the cylinder, and ports and slots in the piston, which entirely obviate any slide-valve and other frictional parts, by means of an arrangement similar to the regulator of a pump, which on the return stroke of cylinder, forces fresh pure air into cylinder to cool it, whilst a like arrangement acts at front of cylinder, which is similar to ordinary steam cylinder. If the drawings would like to be seen, I should be glad to send them, and also measurements to the Editor, as I feel they would interest a good many readers. The engine is extremely simple, and any reader could make one for himself, so long as he pays a Royalty of £1 to the patentee.—W. BUNDY.

[57142.]—**Planing Machine.**—Can "J. H." say how to make a good cheap foot-power planing machine?—W. BUNDY.

[57143.]—**Dr. Eder's New Sulphite of Ammonia Developer.**—Will some correspondent who has tried this developer, kindly say whether successfully or not, as I find it impossible to get any image without the addition of ammonia, which is not mentioned in the formula given in the ENGLISH MECHANIC last week?—J. J. S. C.

[57144.]—**Bright Silver Plating.**—Would anyone kindly give me information how to make a solution for silver plating, bright, without brushing?—A CONSTANT READER.

[57145.]—**Gas Engine.**—I bought a two-man gas-engine, Hutchison's patent, from the London Gas Engine Co., Dalston Junction, London, about three years ago, and circumstances prevented me starting it till now. I find it won't go: it gives an explosion every now and again and blows out the light; the result is it can't keep itself moving. I am informed the company is defunct. Can any of "ours" give any particulars about this engine, and why the explosions do not take place at every turn of the crank, and what are the merits of Hutchison's patent, if there is such a patent? The engine is perfectly useless to me. I shall be much obliged for any information—M. C. J.

[57146.]—**Instantaneous Shutter.**—To MR. LANCASTER.—Will Mr. Lancaster tell me, (1) if the Le Merveilleux is rapid enough for an instantaneous shutter, and would the shutter made to fit the instantograph fit Le Merveilleux? (2) Wouldn't it be possible to make movable stops to the lens of Le Merveilleux?—it is so very dark for focussing in very dark places, without a larger stop; this is the only drawback to his otherwise perfect apparatus.—R. A. R. Bennett, Walton Manor Lodge, Oxford.

[57147.]—**Geometrical. — Science Examination, May, 1884; Mathematics, Stage I.**—Given the distances of the angles of an equilateral triangle, to a point within it, to construct it.—BETA.

[57148.]—**Small Shaping Machine.**—Can any readers give a sketch of small shaping machine, such as could be driven from flywheel of lathe?—L. BALDWIN.

[57149.]—**Brightening Small Goods.**—I read in Watt's "Electro Metallurgy," that a few drops of bisulphuret of carbon, added to a silver solution, will impart brightness to the article in the bath. This would be of great service to me, as I have something to silver which cannot be scratch-brushed; but on applying to a manufacturing chemist, of whom I generally have my goods, I was informed that bisulphate and bisulphuret are the same thing. Will you kindly let me know if it is so, as the bisulphate which he sold me; will not produce the effect which it is stated by Watt to do? Also can you let me know of any easy method of brightening small goods, such as earrings, studs, &c.?—J. H.

[57150.]—**To Mr. Bottone.**—Having completed a small dynamo, Jones's upright castings and laminated A., F.M.'s, 9in. by 5in., A. 2in. diameter, 1lb. 20 s.c. wire on A., and 5lb of 16 d.c.c. on each limb of fields; pulley on A., 2in. diameter; driving wheel (plenty power) 26in. diameter; speed, 100 revolutions per minute, *i.e.*, driving wheel. Now when the band is put on A. pulley, the current seems almost nothing; it would not light up one 20 c.p. Swan lamp. I tried three and four lamps in parallel arc, with no better result. I have followed instructions in your work on the dynamo as to winding, &c. Insulation to my knowledge is perfect, also connecting up. Will you kindly say if speed is too fast or slow, and whether being too particular about A. insulation or not, is the fault? In other words, I put four or five layers of cotton between iron and wire of A.? My conducting wire to lamps was No. 16 rubber c., is this too small? Would a few convolutions extra on one limb of one field be at fault, as this is so? How many 10 c.p. lamps should I light? Connections:—Positive brush, to inside wire of F.M.; outside wire, to other brush, and from brushes to lamps—is this right? Kindly say what resistance each lamp should have, also where the fault lies, and oblige.—ONE IN A FOG.

[57151.]—**Problem.**—Can any kind reader work the following? I find that I can engage 15 workmen for 11 weeks, or 31 workmen for 5 weeks at uniform wages, and in either case pay the wages exactly by means of the interest now accumulated on a certain sum of money, and that which will arise during the particular period of engagement. For how long could I engage nine workmen on the same principle?—JUDY.

[57152.]—**Incandescent Lighting.**—Is it possible to light incandescent lamps, and drive a shunt-wound motor on the same circuit, the current being generated by a shunt-wound dynamo? The motor has to be frequently stopped and reversed.—W. E. H.

[57153.]—**Problem.**—Will any kind reader work the following? In a field in which grass grows uniformly, suppose that 31 oxen can consume 8¾ acres in three-quarters of the time in which 15 oxen would consume 5¼ acres, and that 22 oxen would require three days longer to consume 7½ acres than 20 oxen would require for 6¼ acres. In what time would the 31 oxen eat up the 8¾ acres?—JUDY.

[57154.]—**Horse Taming or Breaking.**—Could any of your readers kindly advise me? I have a very fine pony, about 14 hands high, which has acquired a will of its own, it also kicks in harness. Beating it only makes it worse, and it has now commenced to kick with its fore feet. I understand there were two professional horse tamers lecturing in one of the circuses in London lately. Can anyone say, from experience, whether their secret is worth the £5 5s. charged, and if it has a lasting effect on the horses? Is there any really good book on the subject?—M. H. J.

[57155.]—**Microscopic.**—Last evening as I turned over the pages of our "E. M.," I found at page 542, for Feb. 11., 1881, a letter on testing microscope objectives, in which it is stated as a test for a ½in. that it will, if good, show the flagella on a monad with the C and better with the E eyepiece. I thought I had good objectives; but my ¼ or ⅛in. will not even show this, and it is little better than glanced with ⅛in.; indeed, I understood that the flagella of this minute organism was adduced as a test for his new ⅛in. by a distinguished optician. Will some friend say if ½in. objectives are now made to be capable of this perfection? I have never seen such, but then I live in the country far away from the voice of science, unless that I may call the hum of the threshing machine or the clatter of the mowing machine scientific intonation. If a ½in. glass will do what previously we required a battery of objectives to perform, there need no longer be the trouble with nose-pieces constantly changing, &c., as all can be done by simply sliding in our various eyepieces. I shall be impatient to know what our scientists will answer; as for joy of this hidden treasure, I feel like selling all I have and buying this multum in parvo objective.—E. B. FENNESSY.

[57156.]—**Gauging Railway Waggon Axles.**—During an investigation the other day into the cause of several railway waggons leaving the rails, I understand one of the company's waggon inspectors said, when gauging the wheels of a load of coal, that one axle was a little strained, but nothing to speak of, and he had no doubt that was due to the waggon being under load. Now what I should like to know is, (1) Should the axles of waggons be deflected when under load and not when empty? (2) If deflection takes place at all, does it continue while the wheels are revolving, and (3) when the gauge shows the wheels are 1¼in. wide on the one side, how much is the axle bent, and also any other information respecting above subject will be gratefully received by a—THREE YEARS' SUBSCRIBER.

[57157.]—**Steam Pipe.**—I have heard that if iron steam pipes are connected to a copper boiler, the copper corrodes the iron. Will some reader inform me if it is so, and if so, how the difficulty can be got over?—J. L.

[57158.]—**Bird Taming.**—I want some information respecting the taming of small birds, as practised by those who use them for exhibition purposes, and as the subject will be of interest to many, I hope you will allow the inquiry to be made through the columns of "ours." I want to get an aviary of small birds, all of them so tame as to come on the finger at any time, and I feel sure that some of our readers can supply a description of how it is done. I have tried to get the information from the Italians who are to be found at seaside resorts with performing birds tame enough to be let out of the cage without the slightest disposition to fly away. This is especially noticeable with the green Budgerigars, a naturally wild bird that can never be tamed by petting, and yet these people tell me that they tame them and teach them to perform in a very short time, though they will neither say how they do it, nor sell the birds. A good living might be made by those who understand the subject, by taming them for sale as pets. I have often advertised for them, but only once succeeded in purchasing a really tame small bird.—W. P.

[57159.]—**Watch Query.**—I have a watch (gold verge) probably over a hundred and twenty years old, maker, S. Nickisson, London, in good order except inasmuch as it wants a new hair spring, the collet only remains; curb pins in edge of cock restrain balance wheel to an arc of 35deg. I have put on a new spring, but it is evident it is not suitable, as the watch gains half an hour each hour as nearly as may be. Will some practical watchmaker tell me the defect and give directions for remedying it, and also give rules for fitting hair springs, generally, how strength and length are found?—and oblige—CARIBBEAN.

[57160.]—**Copper Balls.**—Will Mr. Davies or some kind reader account for the decay of the solder used in putting the shells together for supply cisterns where warm water comes in contact with same, and the remedy?—and oblige—ONE IN TROUBLE.

[57161.]—**Wooden House.**—I have for some time thought of building myself a wooden house (not a shanty). Can any correspondent refer me to examples, or give hints?—ZYLOS.

[57162.]—**The Micro O.G.**—To "ROS CRUS."—I should like to thank you for the information you have given. Having followed your instructions, with a little practice I found it possible to grind and polish small lenses, working them to any curve. Instead of using pitch to stick the discs on to the chuck, I found Lapidary's cement to work better: it has a higher melting temperature and more holding power. For grinding and polishing I use leaden laps finishing with a mixture of rottenstone and rouge. I had a great difficulty to overcome scratches when putting on the fine finish, until I found out they were due to fine specs of glass which broke off the edges and got under the polisher. Will you kindly supplement your information by more? You say (24413) "Grind a plano convex flint of 3·5in. radius, and a double convex to match;—when cemented these are our middle." Do you mean cement them in the tube, or together? If the latter, how is it done? Having made the o.g., will you kindly say what other lenses are required to complete the microscope, and how placed, and if all the lenses have the metal turned over the edges to fasten them in? Having had some experience with a lathe, the screwing and fitting will not be so great a difficulty as the lenses. Again many thanks; through your kindness I may now become master of an instrument, for the present state of our trade (jewellery) made the purchase of one rather remote.—J. T.

[57163.]—**Employment at the Arsenal.**—In what manner should an engineer proceed to obtain employment in the arsenal at Woolwich?—J. G.

**Every Workman** connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

**Holloway's Ointment** is not only fitted for healing sores, wounds, and relieving external ailments, but rubbed upon the abdomen it acts as a derivative, and thus displays the utmost salutary influence in stomachic disorders, derangements of the liver, irregularities of the bowels, and other intestine inconveniences which mar man's comfort.

## ANSWERS TO CORRESPONDENTS.

◆◆◆

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

### HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, July 29th, and unacknowledged elsewhere :—

W. H. NELIS.—Alvan Clark.—E. J. Warmington.—Westinghouse Brake Co.—G. S. Forbes.—B. A.—Clutch.—J. D.—W. B. P.—Dr. Royston-Pigott.—M. A.—Magi.—F. M. S.—Improver.—Improvement.—H. A.—H. F.—T. R. Clapham.—C. R. Marten.—Thermo.—Rector.—Quarryman. — Coral.—Nawt.—K.—T. Handel.—T. Watt.—Bacchus.

A. M. J. (Brasing bandsaws has been described many times. The best plan is to use the tongs with heavy beaks, which are made white hot, and grasp the ends of the saw until the spelter runs. If you must use gas, Mr. Fletcher, of Warrington, can supply you with a suitable apparatus; but we suspect that he will not recommend gas for such a job as a bandsaw. 2. The best material is a sort of water-glass; but it is better to purchase such things of those who have the requisite appliances for making sound goods. See, however, p. 297, No. 845, and the indices generally.)—SUBSCRIBER. (For methods of sharpening razors, see p. 311, No. 793, and the indices.)—GAMMA. (Would it not be a gratuitous advertisement? See indices for methods of making small batteries. Patents are often sold, and the articles become known by the name of the purchaser.)—TAY. (Spongy iron is the ore reduced to the metallic state without fusion. You can gather information about it by referring to back volumes under the heads Spongy Iron and Filtering.)—OHM. (The principle is simply producing a current by rotating a coiled armature in front of magnets. If you refer to p. 295, you will see the handle.)—E. E. S. (Marine glue, which requires heat to melt it; or the mixture of quicklime and white of eggs. The latter must be used quickly.)—ENQUIRER. (You should look through the back volumes. It is done by immersing the article, first thoroughly cleaned, in a solution of gold or silver, placing a piece of clean zinc in contact. The coating is not very durable, and the process is not adopted for good work.)—L. R. (See the indices of recent volumes. Several model boilers have been illustrated in the last four or five volumes, and you will probably be able to decide for yourself which pattern you will attempt.)—FRRAZER. (Pictet's domestic ice machine illustrated on p. 243, Vol XXXVI., will probably suit you; if not, look up the subject in back volumes. You know, of course, that a rather expensive plant is required.)—J. K. (See any treatise on mensuration, or refer to back numbers, in which some problems of the kind have been answered.)—W. E. H. (We do not know whether the American plan is patented; but should think it most likely that it is. The differences are probably in details. We have already mentioned the electrical railway at the Inventions.)—CHAS. COTON. (There are no "books" on the subject. You will find a good deal of information in back volumes—especially Vol. XX., pp. 197, 225, 250, and in Allen's "Commercial Organic Analysis.")—IMPROVER. (If we recollect the work you mention is the only one on the subject. At any rate, we know of no other. If you put a definite query in our columns, no doubt you will obtain the required information; but how to forge the ironwork for locomotives is too vague.)—CONSTANT READER, Wednesfield. (If you were a "constant reader," you would know that Prof. S. P. Thompson has published a work on "Dynamo-Electric Machinery," and that some of it appeared in our columns. The work is published by E. and F. N. Spon, Charing-cross.)—SYLVANUS WEAR. (When there are so many good books on the subject, it would be invidious to mention any as the best. You will find certain works recommended by correspondents in back volumes; but as a matter of fact, Longmans, Lockwood, Macmillan, Cassell, Spon, and other publishers issue standard textbooks, which are quite suitable for candidates for the South Kensington Examinations.)—A CONSTANT READER. (The "day eyepiece" is exactly what you want. Why not look through your back numbers.)—G. FAYER. (A "line" is one-twelfth of an inch. 2. Try the effect of a warm flat iron, interposing some thick blotting-paper. If repeated attempts will not remove it all, apply ether and the blotting-paper to soak it up with the grease.)—E. EDWARD TAYLOR. (We do not think you will succeed in getting a railway company to take it up, for the simple reason that there are several devices of the kind which they could use if they felt inclined to.)—WATER DRINKER. (The taste of the tar will go off after a time.)—SUFFER. (Try a little magnesia and regulate your diet better, using oatmeal porridge instead of bread, and avoiding smoked and salted flesh.)—POROUS POT. (Use a mixture of pitch and rosin.)—SIGNAL. (Many of our readers could oblige you with full particulars of the block system, but we should not be able to spare space. Briefly, it consists in dividing a line into sections and blocking it by signals sent from one box to another. The line is normally "blocked," and a signalman puts his signal "off" when he receives telegraphic notice of train on line, unless, indeed, he wishes to stop the train. when he leaves his section blocked. The details differ on different lines, and there are patented systems. See Barry's "Railway Appliances," Longmans.)—J. B. (Shake in through a paper funnel, and apply heat to drive any air-bubbles out.)—YOUNG MECHANIC. (Several in back volumes. See pp. 14, 65, Vol. XXIX., or go and look at them in the Inventions.)—K. Z. (A Barlow lens will not always improve definition. It is an achromatised negative or concave lens, placed within the converging rays of an object-glass, about 4in. from the field lens of the eyepiece. It produces an increase of magnifying power without necessitating an increase in length of tube. The cost can be easily ascertained from opticians' lists.)—TAILER. (The symptoms of painter's colic, due to lead poisoning, are costiveness, violent pains about the navel, and convulsive spasms in the intestines. The best means of prevention is the use of sweetened water as a beverage, slightly acidulated with sulphuric acid.)

## CHESS.

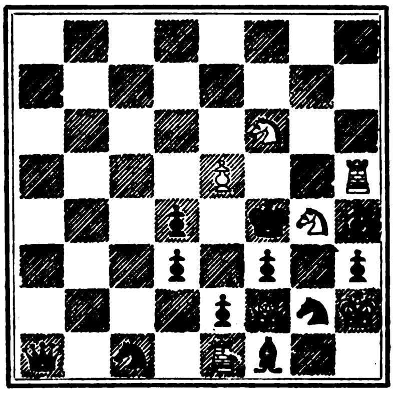
### PROBLEM DCCCCL—"ON THE MOVE."

*Black.*



*White.* [7+11

White to play and mate in three moves.

SOLUTION TO 948.

| *White.* | *Black.* |
|---|---|
| 1. B-Kt 4 | 1. P takes B (*a*) |
| 2. Kt-B 5 | 2. Anything |
| 3. Q or B mates | |
| | (*a*) 1. K takes B (*b*) |
| 2. Q-K 2 (ch), &c. | |
| | (*b*) 1. K-K 4 (*c*) |
| 2. B takes P (Q 6) (ch), &c. | |
| | (*c*) 1. B-B 5 (*d*) |
| 2. Q-Q 3 (ch), &c. | |
| | (*d*) 1. Anything else |
| 2. B-Q 3, &c. | |

### NOTICES TO CORRESPONDENTS.

CORRECT solutions to 947 by F. O'N. H. (awkward), A. A. E. Lecluse (very good), G. T. Stringfellow.

To 948 by F. O'N. H. (tough), A. A. E. Lecluse (excellent in all respects), Streetgate (good; a new departure;—but main play incorrect after first move—ED.) A. S. Olver (good), and H. Culmer (1. Kt-Q 6 wrong however after 1. $\frac{}{\text{K takes B}}$).

To 949 by F. A. Vincent, A. A. E. Lecluse (rather good), Streetgate, A. S. Olver, Rev. W. Anderson (Old Romney), and H. Culmer.

W. A.—By main play of course we meant *your* main play: if 1. $\frac{}{\text{K takes B}}$ 2. $\frac{\text{Kt takes P}}{\text{B takes Kt}}$ and there is no mate. This is what you originally sent.

MR. VINCENT has gained the first prize in the Second ENGLISH MECHANIC Game Correspondence Tourney, having won all the fifteen games except three (with Messrs. Blake, Nash, and J. Pierce) which were drawn. The other prizes are not yet settled.

## USEFUL AND SCIENTIFIC NOTES.

◆◆◆

**Effect of Acid upon Iron.**—The effect produced upon the appearance of iron by the acids employed in the process of etching presents some peculiar characteristics, depending upon the kind of iron treated. Soft or sinewy wrought iron of excellent quality is attacked so equally by the acid, and so little acid is separated, even after several hours' action, that the surface remains bright and smooth; fine-grained iron acts the same, the surface being still smoother, but a little darker; coarse-grained and cold short iron is attacked much more violently by acid than that just mentioned—in ten minutes, especially with cold short iron, the surface is black. After thirty minutes a black gloss can be washed off, and the surface will remain black in spite of repeated washings, and exhibit numerous little moles; certain parts of the iron are usually penetrated deeper, while others, although black and porous, offer more resistance. By allowing the acid to act for an hour or so, and then washing, drying, and polishing with a file, a distance picture is obtained. As is known, malleable cast iron rusts more easily than wrought iron, and it is an interesting fact that the action of the acids is also violent, the surface being attacked very intensely. Grey pig-iron acts like steel, and the etched surfaces have a uniform grey colour.

**Elective Alcoholic Fermentation.**—It is a fact that in a mixture of levulose and glucose the fermentation does not go on equally in the two sugars. Hitherto the question has remained unsettled whether the sugars are changed successively or simultaneously and at equal rates. M. Bourquelot asserts that not even the purely physico-chemical conditions of the fermentation have been worked out. He has worked at mixtures of maltose with levulose and glucose with levulose. In a first series of experiments conducted at ordinary temperatures, it was found that these sugars ferment simultaneously, though at unequal rates. Levulose changed more rapidly than maltose, but less rapidly than glucose. But this relation was not maintained, so that if yeast possess an elective faculty, this alters from time to time—a conclusion which appears to be absurd. M. Bourquelot has determined that the so-called elective fermentation is dependent on the temperature, state of dilution of the fluids, and the amount of alcohol formed during the fermentation; that the rate of fermentation depends on the physico-chemical conditions, and not on any selective power of the yeast. Sugar, in order to be converted, must come into direct contact with the protoplasm of the yeast cell, and must, therefore, traverse the cell wall. The conditions which determine the rate of osmosis of the cell wall are, without question, both physical and chemical. The results thus obtained are in harmony with theoretical considerations. A full account of the investigations may be read in the *Répertoire de Pharmacie* of July.

**Inhalations in Phthisis.**—During recent times we have heard a great deal of the value of antiseptic inhalations in the treatment of phthisis. A further clinical investigation has been undertaken by Dr. Renzi, of Naples. He has employed inhalations of four kinds: First, of idioform and essence of turpentine, of which two to six drops every hour or two hours of a liquid containing one part of iodoform to twenty-five parts of spirit of turpentine were used; fourteen patients were submitted to this treatment. Secondly, iodine volatilised every day in a bedroom 30 cubic mètres in capacity in the amount of ·40 to 2·10 grammes, heated in a capsule by means of a sand bath; three observations were made. Thirdly, sulphuretted hydrogen, evolved by the action of sulphuric acid on powdered sulphide of iron in such proportion that every cubic mètre of atmosphere in the chamber should contain seventy-five cubic centimètres; seven cases were thus treated. Lastly, sulphurous acid, made by burning sulphur in a closed chamber, so that there should be forty-three cubic centimètres of the gas in a cubic mètre of the atmosphere. Dr. Renzi has found that the first two methods of treatment ameliorate the local condition and general nutrition, without modifying the pyrexia, diarrhœa, or nocturnal sweatings. Inhalations of sulphuretted hydrogen and sulphurous acid seemed to increase the general strength, improving the nutrition, and increasing the quantity of urine discharged. Sulphuretted hydrogen had a special influence on the respirations, which were diminished in frequency; it also exercised a beneficial influence on the cough; but the fever, diarrhœa, and diaphoresis were not relieved. Of all the inhalations, the author decides in favour of turpentine and sulphuretted hydrogen.—*Lancet.*

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words .. .. .. .. .. .. .. | 2 | 6 |
| Every additional eight words .. .. .. .. | 0 | 6 |

Front Page Advertisements Five Shillings for the first 40 words, afterwards 9d. per line. Paragraph advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

| | s. | d. |
|---|---|---|
| Twenty-four words .. .. .. .. .. .. | 0 | 3 |
| For every succeeding Eight Words .. .. .. | 0 | 3 |

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. | d. |
|---|---|---|
| Sixteen words .. .. .. .. .. .. .. | 0 | 6 |
| For every succeeding Eight words .. .. .. | 0 | 6 |

*** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday, to insure insertion in the following Friday's number.

## TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve months, Post Free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII., XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., and XL., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words, and 3d. for every succeeding 8 words.*

**Good Value Offered** (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—Caplatzi, Science Depot, Chenies-street, near British Museum. Established 1862.

Handsome **Pipe Organ**, 7 stops, 1½ octave pedals, hand and foot blower; suit chapel; room wanted. Exchange American Organ or Piano.—Wales, Hemsworth, Yorkshire.

A splendid double-barrel **Gun**, all complete, with machines, to be exchanged for a 4 or 4½ centre Lathe; iron bed preferred.—Address, T. Bullock, 169, John-street, Workington.

Three-pint **Bottle Bichromate**, perfect; pint Smee, two Medical Coils. Exchange the lot or part; offers wanted.—Lord, Victoria street, Radcliffe, near Manchester.

Six-cell Edco **Battery and Motor**, in good order. Exchange for Bicycle, Drilling Machine, or good Lathe, or anything useful.—T. S. Barratt, 40, Bentinck-street, Ashton-under Lyne.

Three-draw **Telescope**, by Ripley and Son, electroplated, 1⅜in. object-glass: wanted Drawing Instruments.—Joiner, 4, Temperance-terrace, White Horse-lane, South Norwood.

Duplicate silver **Waltham Watch** of the Melbourne Exhibition, cost 10 guineas, price £4 10s. Part exchange; Drawing Instruments or offers.—Address above.

**Harmonina** wanted, about 3 octaves, keys width of piano, or portable Harmonium; also good Music. Exchange.—H., Southcote House, Onslow-road, Richmond, Surrey.

Wanted, a Singer **Hand Sewing Machine**, must be in good condition. Approval desired. Exchange.—F. O. Bell, Belleville, St. Mark's, Cheltenham.

**Aquarium**, octagon form, with sloping top, 16 by 15, without top; would exchange a strong Parrot's Cage or first-class Microscopic Objects, or offers.—R. M., 24, Park-road, Clapham, London, S.W.

I have a very fine, sweet, mellow-toned old **Violoncello**; it has been in the Dyson family for 120 years, suit solo player, value £9 9s. Would exchange for a front-steering Tricycle, don't mind if a little out of repair. Also new bow for same.—Address, Eli Dyson, Thomas-street, Lindley, Huddersfield.

Vols. I. to XIV. "**Mechanic's Magazine**," superior bound, good as new; 10 Vols. "Family Friend," bound: in exchange for small Lathe. Also wanted, cheap, illustrated book on turning.—W. J., 78, Viaduct-street, E.

**Dynamo Machine**, with hand-power wheel, cost £5 10s. Will take £3 10s., or would exchange and pay difference for one that has been used for electro-plating, and capable of depositing not less than 1 dwt. of copper per hour.—J. Dawson, 56, London-road, Sheffield.

Rare opportunity.—Splendid 5in. **Slide-rest**, also Lathe, Bed Standards, and Treadle, by H. Milnes; offers wanted.—Apply to F. Underwood, Beverley.

**Eyepiece**, Huyghenian, astronomical, third-inch, with sun-glass, cost 15s. Wanted, 2in separating Micro-Objective.—Bartlett, 3, Ainslies Belvedere, Bath.

**Dulcimer** for anything useful.—C. CUSWORTH, 30, Ellington-street, Barnsbury, London, N.

"**English Mechanic**," Vols. XIV., XV., XVI., XVII., complete; Vols. V., VII., IX., XI., XII., not complete, and duplicate numbers; list sent; what offers?—Post Office, Lower Ford-street, Coventry.

Wanted, **Lists**, Engineering, Architectural, and Scientific Books; Civil Engineers' "Proceedings," early vols., "Engineering," any vols. Exchange Instruments, or cash.—Z. C., 62, Loddiges-road, Hackney.

Splendid model Horizontal **Slide Valve Engine**, inch stroke, all brass, with 3-grooved pulley, balance crank, and heavy flywheel, and lubricator on cylinder, new, on mahogany stand, cost 50s. Exchange for Lathe-heads, 3 to 5-inch centre.—J. Jackson, 135, Trafalgar-road, Burnley.

## THE SIXPENNY SALE COLUMN.

*Advertisements are inserted in this column at the rate of 6d. for the first 16 words, and 6d. for every succeeding 8 words.*

**Motor Castings**, materials for Electric Bells, Batteries, Galvanometers, Intensity Coils, Microphones.—King, Mendham, and Co., Bristol.

**Insulated Wire Table**, showing size, weight, resistance per foot, feet per ohm, &c., price 3d.—King, Mendham, and Co., Bristol.

**Standard Ohm**, in box, copper poles, guaranteed correct to ten thousandth of ohm, 21s.—King, Mendham, and Co., Bristol.

Wimshurst **Influence Machine**.—Sole Manufacturers of Improved Pattern. Numerous testimonials as to thorough efficiency.—King, Mendham, and Co., Bristol.

**Galvanometer Cards**, improved for tangent and ordinary combined, 2½in., 8d.; 4in., 10d.; 6in., 1s.; post free.—As above.

Write for **King, Mendham, and Co.'s** large new and reduced Price List, post free 4 stamps.

**Trouser Lengths**, 5s. each. Cheap Cloth for Ladies' Dresses, Mantles, Boys' Suits.—Hewitt, 27, Winfield Mount, Leeds. Patterns free.

**Electric Depot**, 10, Deansgate, Manchester.—Electric Breast Pins, 25s. Electric Bells, 4s. Induction Coils, 8s.—Millar, Proprietor.

**Chemical Apparatus**. — Catalogue, 90pp., 500 illustrations, posted 2d.—W. Hume, Lothian street, Edinburgh.

**Photographic Apparatus and Chemicals** for professionals and amateurs. See new illustrated catalogue, post free.—Hume, Lothian street, Edinburgh.

New Illustrated Price List of **Screws, Bolts, and** Nuts for Model Work, drawn to actual size, sent on receipt of stamp.—Morris Cohen, 132, Kirkgate, Leeds.

**Do we get Heat from the Sun?** No! Every one interested in science should read this little work. By R. Humphreys. Post free, 1½ stamps.—11, Cambria-street, Fulham, S.W.

**Oils**.—Lard and Olive Oils (substitute for). Reliable information. Stamp for reply.—J. M., 6, Hamlet-street, Bootle, Liverpool.

**Old Scientific Instruments**, Broken Model Engines, &c. For estimate of cost for repairing, relacquering, &c., send particulars to H. P. Lovegrove, Optical Works, Slough, who makes this class of work a speciality.

**Vermilion**, best, 2s. 4d. lb.—PINNELL BROTHERS, 214, Whitechapel-road, London, E.

**Gas Engine Oil** (best), 2s. 6d. gallon.—PINNELL Brothers, 214, Whitechapel road.

**Lathes. Lathes.** Cheap and good. Satisfaction guaranteed. List two stamps. Best make.—Robinson, Catherine-street, Sheffield.

**Sol-fa Dance Music** for any instrument, post free, 7d.—Brown, Music-seller, 1, Grahame-street, Leith.

**Fretwork**.—Catalogue of every requisite, with 600 illustrations, free for 6 stamps.—Harger Bros., Settle, Yorks.

**Marvels**.—Double Opera and Field Glasses, from 5s. 6d. Lists, with engravings, free.—J. B. Dancer's Depot, 63, Hamstead-road, Handsworth, Birmingham.

Tudsbury and Sons' Improved "High-tension" **Wimshurst Machine**, with their new Compound Ebonite Plates.—Edwinstowe, Newark.

**Planing**, not exceeding 10in. by 10in. by 8in.—B. W. Clegg, 18, Belinda-street, Hunslet, Leeds.

For **Model Work** (wheel-cutting in brass only); also Boring, Turning, and Screw-Cutting.—Clegg, as above.

**Violin** for sale, magnificent solo tone, perfect preservation, labelled "Antonius Stradvarus, 1690," with case and bow, suit lady or gentleman; 25s.; cash needed; approval with pleasure.—Mrs. Stokes, 50, Myddelton-street, Clerkenwell.

**Household Dyes**, 20 colours, cheap, cleanly, and expeditious. Sold by the manufacturer in 1d. and 6d. packets; gross, 7s. and 42s. Sample 2 or 7 stamps.—T. E. Hoyle, Blackley, Manchester.

**Mirror Galvanometer**, 1,900w., 35s. Polarised Relay, 250w., 15s. Rheostat, 21w., 10s. 6d. All new. Photo. 6d.—Vincent, 57, Princess-terrace, Regent's Park, London. Letters only.

**To Chemists and Aerated Water Manufacturers**.—Pure expressed Lemon Juice, three shillings per gallon.—J. Meadows, Distiller and Cordial Manufacturer, 44, Humberstone-gate, Leicester.

Steel **Name Stamps**, 3d. per letter. Figures (set), 2s. 4d. Letters, 6s. 4d., per post.—E. F. Baldwin, Robinswood-hill, Gloucester.

**Model Steam Engines**, made or repaired, separate parts fitted up, boilers made to order; sets of castings of every description.—Lucas and Davies, 21, Charles-street, Hatton Garden, London.

**Boiler**, vertical, 1-horse, £6. Engine, £3; in excellent order.—79, Dudley-road, West Bromwich.

**Batteries**.—To the Trade. Pint Bunsen's, Daniell's, Bichromate, 8s. dozen; other sizes in proportion.—See below.

**Electro-Motors**, 14s., 24s., and 75s. doz. List free.—J. Hanks and Son, Seaforth, Liverpool.

**Mesmerism**.—Complete written instructions. Success guaranteed. Fee, 2s. 6d.—Professor, 32, Clarendon-road, Anfield, Liverpool.

**Forges**, portable, quite new, circular and square, from 50s. each; bargains.—Lowe, Wallis-road, Hackney Wick.

**Patents, Designs, Trade marks.** Notice.—James Stevenson, The People's Patent Agent, 20, High Holborn, London, W.C.

**Incandescent Lamps** (carbon), 2 to 8 candle-power, 2s. 6d. Trade supplied. Swan's 20 c.p., 4s. 6d.—Patrick.

**Arc Lamps**, several second-hand, £2 each. Powerful Motor or Dynamo, £3; ditto, superior, £4 10s. Clearing out.

**Air Pump**, double-barrel, rack, massive brass fittings, on Spanish mahogany; cost £8; price £3 10s.—Patrick.

**Illustrated List** of Electrical Apparatus, 2 stamps.—Patrick and Sons, 529, King's-road, Chelsea, S.W.

**Fishing Bait**.—"Red Ching."—This celebrated Chinese bait received first prize in Fisheries Exhibition. Will keep for years. Salt and fresh water fish, attracted from a long distance in large numbers by its peculiar odour and colour, take the bait voraciously. One packet will take bushels of fish.—Post paid, 1s. 2d.—Agent, Dr. Evans, Importer, Shirley, Southampton.

**Oxygen Gas**, compressed in cylinders, handiest and safest for limelight.—Clarkson, Compressed Gas Chemist, Bartlett's-buildings, E.C.

**Oxygen Gas**, compressed into iron bottles, liquid nitrous oxide and carbonic acid.—Clarkson, Compressed Gas Chemist.

**Oxygen Gas**, compressed into iron bottles; prices on application.—Clarkson, 28, Bartlett's-buildings, Holborn, E.C.

Astronomical **Telescopes** of all kinds and Apparatus or Fittings made by A. Clarkson, 28, Bartlett's-buildings.

**Eyepieces**.—Huyghenian of any power to fit any telescope, 15s. each. Sun Diagonals, £1. Star Diagonals, 30s.

Astronomical **Telescopes**, second-hand, by best makers.—Clarkson, 28, Bartlett's-buildings, Holborn, E.C.

Bisschopp **Gas Engine**, 2-man, in splendid working order, price £20.—Stelfox, Woodland-hill, Gipsy-hill, S.E.

Parts of professional-made six-stopped **Organ** for sale cheap.—Ferguson, 5, Somerset place, Rotherhithe.

**American Organ and Pedal Actions**, complete or separate. Cheapest in the trade.—Tarr and Co., Argyle-street, Swansea.

**Lathe**, 5in. centre, screw-cutting, partly finished, cheap.—R. D. Smith, Fazackerley-street, Chorley.

Engineer's **Stocks, Taps, and Dies** from ¼in. to ¾, equal to new, cheap.—R. D. Smith.

**Blocks and Rope**, pair of strong 4 sheave, perfect, 25s. Worth double.—R. D. Smith.

**Blacksmith's Tools**, about 7cwt., punches, swages, sets tue iron, &c., 1½ per lb.—R. D. Smith.

**Shafting, Pulleys, and Hangers**, several lots cheap. State wants.—R. D. Smith.

**Lathe Heads**, 10in. centre, back-geared, 60s.; worth double.—Rigby D. Smith, Fazackerley, Chorley.

**Iron Planing** by steam, 30 by 10 by 10in. Speciality, gas engine valves.—Patrick, Engineer, Chelmsford.

**Search your Back Columns** (from May 8) for Stanley's weekly announcements; you will be amply repaid.

Brass **Model Engine Castings**, rough or finished, see new list (stamp).—Wood, Dalley-street, Broughton, Manchester.

**Patents, Designs, and Trade Marks** procured on very moderate terms.—P. M. Rogers, 21, Finsbury-pavement, E.C.

**Hand Drilling Machines**, strong and well made, ⅝ holes, from 30s.—S. Brechino, Mareham-le-Fen, Boston.

Good ordinary **Perambulator**, with best fellied wheels, 13s. Wicker Bassinette, reversible and china handle, rubber tires, splendid carriage, 44s.—Thomas Ellingworth, Leighton Buzzard.

**Iron Printing Press**, chase 6⅜ by 4⅜, about 10lb. of type in case, 25s.—Below.

Powerful **Induction Shocking Coil**, with brass tube regulator and handles, platinum pointed, 10s.—Below.

Horizontal Slide-Valve **Engine Castings**, ¾in. bore, cylinder finished, 9s. Amateur's cylinders bored, &c.—Below.

Silk-covered **Copper Wire**, No. 26, per dozen yards, 4 stamps, post free.—Mackett, King-street, Maidstone.

**Photography**. — Reliable **Sodic Sulphite** for Developing.—The anomalous results obtained with this salt arise from the presence of impurities in the commercial article. 1lb of pure Special Sulphite, in handsome glass stoppered bottle, box included, sent, carriage free to any address in the United Kingdom, on receipt of Postal Order for 3s. 6d. Orders cannot be booked.—A. Boake and Co., Stratford, London, E.

Wanted, Screw-cutting **Foot Lathe**, 5in. centre preferred.—Description and price to George Binks, 138, St. Paul's-street, Hull.

**Model Engine Castings**. — Makers of Model Engines should send for a Set of Hughes' Iron Castings. Best and softest metal. Lowest prices in the trade.

**Horizontal Engine**, 1¼in. bore, 2½in. stroke, 5s. 6d.; 1⅛in. bore, 2in. stroke, 5s. Working Drawings, 1s.

Double Cylinder **Horizontal Engine**, 1⅛in. bore, 2in. stroke, 10s. Double Cylinder Vertical, 7s. Working Drawings, 1s. 6d.

Vertical **Launch Engine**, 1in. bore, 1½in. stroke, 3s., post free. Double cylinder, 5s. Working Drawings, 1s. 6d.

Half horse-power **Vertical or Horizontal**, 16s. Working Drawings, 2s. Three-quarter horse double-cylinder Horizontal, 17s. 6d.

Send for **Catalogue**, 2d. Six Lithographed Designs, 3d.—Hughes, Mersey Dockyard, 17, Smith-street, Kirkdale, Liverpool.

**Electric Indicators**, Bell, &c., royal letters patent.—Halbart Works, 27, Penton-place, Pentonville-hill. Price list trade.

Electric, Pendulum, or **Drop Movements**, 24s. per doz. Handsome Circular 3in. Bell, 4½ mahogany French polished base, 6s.—Above.

**Hammond's Patent Mitre Frame Cramp** is the best, cheapest, and quickest Cramp for all mitre frame makers; it cramps the four mitres in one action, and so arranged that they can be nailed at the same time; price 22s.; sent on receipt of money orders payable to G. R. Hammond, Snodland, Kent. Diagram sent on application.

Powerful Portable Seaside Astronomical and **Terrestrial Telescope**, 3 inch (bare) object-glass, with sun-glass and brass tripod stand; fits into mahogany box 16 inches by 5 by 4, perfect condition; by Dollond; cost £20; price £7.—Address, Mercator, 15, Bridge-road, Stockton-on-Tees.

**Gas Engine**, vertical, 1 horse-power, Crossley's make, Otto and Langen's patent; bargain, £20.—Apply, Mercator, 15, Bridge-road, Stockton-on-Tees.

Largest size Ross Binocular **Microscope**, 6 eyepieces, 6 selected object-glasses, quantity of apparatus, mahogany cabinet; cost £86; price £40.—Address, Mercator, 15, Bridge-road, Stockton-on-Tees.

**Piles**.—Worst cases cured first application. "Indian Ointment," 13 stamps. "New African Tonics." Packets, 60 stamps (in proof for short time, 30.)—Thomas Palmer, St. Helen's, Auckland, Durham.

**Read the Lines of the Hand**.—Chart, with full particulars, 7d.—H. Dyke, 21, North-street, Taunton.

Half H.-P. **Horizontal Engine**, new, perfect beauty, engineer made; also 4in. centre Bench Lathe, iron bed, new; must sell; great sacrifice; price £5 10s., or separate; inspection invited.—Apply or write, 166, Siddals-road, Derby.

**Lathe**, 4in. centre, 3ft. planed bed, standards, flywheel, crank, chucks, and drills; first 30s. will have it; given away. Seen after 3 p.m. Saturday.—102, Teviot-street, St. Leonard's-road, Poplar, E.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
*FRIDAY, AUGUST* 7, 1885.

## LOCOMOTIVE MANAGEMENT.*

THE work on the locomotive engine which Mr. Sinclair has written does for the American railway man what Mr. Michael Reynolds's books have done for British drivers and firemen. Originally intended to be confined to dealing with locomotive running alone, it gradually expanded until it became a practical treatise on the running and management of locomotive engines, showing the performance of different kinds as regards economy and despatch, and giving directions regarding the care, management, and repairs of all locomotives and their connections. The author is, or rather was, a knight of the foot-plate, and from an early period in his career made a practice of noting down facts about the working of his engines, with the view of studying out at leisure anything which was not quite clear. This practice he continued when appointed to take charge of the roundhouse at the mechanical headquarters of a railway in Iowa; and, as most of our readers will understand, Mr. Sinclair soon obtained a mass of raw material, which he presents in a useful, not to say valuable, shape in the book before us. The information given is couched in simple language, and no attempt is made to instruct in mechanical engineering in anything beyond elementary problems. Mr. Sinclair has observed that the practice of applying to books for information concerning their work is rapidly spreading amongst the engineers and mechanics of the United States, and to such men, earnestly toiling up the steep grade of Self-Help, he dedicates his book. In this country the "locomotive engineer" is called the driver; but there is no reason why he should not earn the title "engineer" by a diligent study of such works as this. At one time all that was expected of a driver was to bring his train in to the minute without damage and with the minimum amount of wear and tear; but the driver who would aspire to take a foremost place nowadays must understand the principle of his engine thoroughly, be perfectly familiar with the laws of steam, be able to do such jobs as setting the slide-valves, and know almost intuitively when anything is wrong, and where to look for it. In other words, the successful driver is the man who gets most work out of his engine at the least expense, and always keeps time—except, of course, when delayed by circumstances beyond his control. Mr. Sinclair suggests that young drivers and firemen would do well to take the advice of Socrates, and gain knowledge by persistently asking questions. The young driver should never feel ashamed to ask for information when he needs it, and cannot succeed in solving the problem without it; and he should not be discouraged by a rebuff, for, as a rule, those who refuse to answer courteously-put questions are in the dark themselves. In the United States men are taken on as firemen who are without a previous mechanical training, and Mr. Sinclair advises them to take every opportunity of watching the operations performed by the skilled mechanics at the repair-shops, and especially such operations as are likely to be required from the driver whilst on the road. He also advises them to study works dealing with the special subject, and speaks of the "silly prejudice" of those drivers who boast that all their knowledge is derived from actual experience; such men, he says, never learn much, and they keep the ranks of the mere stopper-and-starter well filled. In this country a driver must of necessity have had much experience, for if he did not start as fire-boy, he certainly commenced as cleaner. In the United States, in the early days, it was considered essential that the driver should be a mechanic, and graduates from mechanical institutes were considered competent as soon as they were perfectly certain about how to start and stop the engine. The late A. L. Holley used to tell a story of one of these engineers, who in a severe winter got firmly stalled in a snow-bank. In its struggles to get free, the locomotive became short of water, and Holley, going to see what chance there was of progressing, found the "engineer" shovelling snow down the smoke stack. But even if a driver has all the "science" necessary, he must also possess other qualities, some of which may be acquired by training, but others not the least important, must be inborn and natural to the man: hence it is the uniform practice of managers nowadays to allow no one to act as driver who has not served for some time as fireman. In the Western States, however, Mr. Sinclair tells us that men are selected for firemen in a rather haphazard way, but on the older roads the European practice prevails of picking out men who have acted as cleaners or been trained on engines running about the yards. A fireman's chief duty is to keep the furnace level and as bright as possible all over, so that the steam-making powers of the boiler are not checked. To do that he must supply coal frequently, and throw it just where it is wanted, and in the case of an express engine with a heavy train that will necessitate the handling of the shovel about every two minutes, and the lifting and placing of more than a ton of coals in a trip of, say, 80 or 90 miles. Such work involves considerable physical exertion, and even those who have had some experience on shunting engines are sorely tried in their first trips with the expresses. The blinding glare of the furnace, the swinging of the engine, and the rather cramped position of the body, soon convince the aspirant that he has undertaken no light task; but happy is the fireman who earns the commendation of the driver after a week's practice. To give an idea of the work to be done, and of the order in which it is done, Mr. Sinclair describes a trip with a fast freight train, and another with an express, introducing incidentally all the points necessary to be observed, such as cutting off, arrangement of the injector and the fire, knowledge of speed, the use of sand, &c. Mr. Sinclair states that it is advisable to keep the steam as near blowing-off point as possible, because then less water is evaporated, and less fuel will be consumed than when running with a low head of steam. A high steady pressure and carefully adjusted expansion are two points which the first-class driver always studies. When fairly started he will link up so that the cylinders get just enough steam to compel the pistons to do their work, and will set his injector to deliver just the quantity of water that is equivalent to the steam being used. Where the road has many up and down grades, or where it has numerous spots at which speed must be slackened, frequent alterations are needed; but the careful driver prepares for these exigencies. On the down grades, when no steam is required, he opens the injector full and closes the regulator, at the same time dropping the links and giving the valves full travel to prevent them being forced off their faces by the compressed air, which would be produced by the motion of the pistons if the links were left in the cut-off position, and also to avoid the risk of drawing cinder dust from the smoke-box into the cylinder. So, when speed has to be reduced, no more brake-power is applied than is necessary; but advantage is taken of all opportunities to keep a full head of steam to be used when the hills have to be climbed. To prevent waste of steam by blowing-off, the driver will let the injector have full play on down grades, and check it when he is using steam freely on a hill, and he will at all times keep an eye on the cut-off, to prevent, as far as he can, the exhaust putting an extra back pressure on the pistons. This little feature of the exhaust is not well understood by novices—nor, for that matter, are experts at one about it. Wide nozzles give free exit to the exhaust, but reduce the velocity of the gases through the tubes; while inordinately constricted nozzles cause back pressure in the cylinder, and produce so violent a blast that they draw the gases through too quickly, and cause the loss of much available heat, while tearing the fire to pieces. Mr. Sinclair contends that double nozzles are preferable, because the single ones impart a tendency to the steam to shoot over into the other cylinder, and so cause back pressure, while the engineer who can reduce the smoke-box temperature by 100 degrees is worthy to rank as a master in his calling, In his earlier chapters Mr. Sinclair contrives to compress a great deal of information about the ordinary work of the locomotive and its two attendants; but when we reach Chapter X. we come to special details, items in the long list of ailments of the engine. Thus shortness of water and pump disorders are sources of trouble to the driver, for they may lead to a burnt firebox, about the greatest disgrace that can happen to him. Chapter XI. deals with injectors, an appliance for feeding water into the boiler which has now almost entirely supplanted pumps. Some designers still use a pump on one side; but they have an injector as well, and the driver is supposed to use the pump only when the injector fails. In the United States the modern practice is, we believe, to dispense with pumps altogether, as injectors rarely fail nowadays, and if one does the driver has always another with which to keep up the feed until he can repair his working injector. Many drivers, however, prefer to work their injectors alternately. Mr. Sinclair, from practical experience, understands all the vagaries of injectors, and there are not a few railway experts in this country who can find a wrinkle or two for them in his book. As a rule, the water supplied for locomotive use along the road is fairly good in this country, but the American driver has to make the best of what he can get, and sometimes he finds himself in want of water "fifty miles from nowhere." Here is a note of Mr. Sinclair's: With water that contains grit, check-valves set in a horizontal position are worthless, and sand, which is trouble enough in a pump, ruins an injector by destroying the tubes. The methods of remedying the defects of the injector are clearly pointed out by the author of this book, and explained by examples which in most cases have occurred in his personal experience. A diagram of the injector principle is given, and full explanations with illustrations of such improvements or modifications as the Sellers' injector, the Monitor, and the Korting injector, and the Hancock inspirator, an apparatus that will feed water of high temperature. A chapter on the care of boilers and fireboxes is almost of purely technical interest, as are those in which various kinds of accidents and the best means of remedying them are described; but the general reader will have his ideas broadened by the perusal of these notes, for they will give him a better notion of the demands which are occasionally made upon the driver. The chapters on the valve-action, the shifting-link, on setting the valves and laying out link-motion, will be useful to others besides railway men; while those on the Stevens valve gear, the Joy gear, and power of locomotives and train resistances will give information to many who are interested in locomotive design and work. Pambour's formula for calculating tractive power is given; but when it is required to find the horse-power developed by a locomotive, Mr. Sinclair says it is usual to employ the indicator. That is rarely done in this country, we imagine, for tractive force is easily calculated by the formula, and the indicator is a useless refinement when the horse-power actually exerted can be readily tested on the road by the dead weight hauled. The formulas for calculating train resistances have been found misleading in American practice. Thus, according to D. K. Clark's formula, the total resistance to a train running on the straight level at fifty miles an hour is 22·6lb. per ton; but Prof. P. H. Dudley with his dynagraph car found the total resistance at fifty-one miles to be 11lb. The resistances, in fact, differ so much in different conditions that Mr. Sinclair says that nothing but a loose approximation can be arrived at, unless indicator or dynamometer tests are made. Experiments made with a freight train on the Erie road in 1881 showed that the total resistance on the straight level varied from 3·25lb. to 4·5lb. for speeds under 20 miles an hour; but those resistances will be considerably augmented by cold weather, and varied also by the condition of the track and the rolling stock. The Westinghouse air brake and the Eames vacuum brake are fully described—the former with much detail and several illustrations. Mr. Sinclair gives also a chapter on the indicator, and urges its use daily on locomotives, as the "graphic tale of the diagram would force out of practice the ordinary habit of running engines with the steam throttled, and indubitable proof of ruinous back pressure would make contracted nozzles intolerable." The use of the indicator may be necessary in American practice; but it is doubtful whether any loco. superintendent in this country would think it worth while to have his drivers taking diagrams. We have, however, said sufficient to show that Mr. Sinclair has written a book which will interest many, while it will be found of great value, if thoroughly studied, by all who have anything to do with locomotive management.

# HISTORICAL NOTES ON THE CASSEGRAIN.—III.

By Dr. Royston-Pigott, F.R.S.

(Formerly Fellow of St. Peter's Coll., Camb.)

## The Great Southern Telescope.

THE Australian trial of this splendid instrument, as reported, must have produced a painful impression both in Ireland and England. The Dublin Report was that 37 M was broken into a heap of stars so large and brilliant that it quite lost the character of a cluster. The planetary Nebula 46 M brought out most strikingly the light-collecting power of this telescope; for it (which in most telescopes is a faint disc) was revealed as a ring bright even on the dazzling ground of the surrounding stars, which here were as brilliant as the components of the Pleiades appear in ordinary instruments. With respect to the Nebulæ, Lord Rosse considered its performance in bringing out the details of the Orion Nebula, 1 M (the Crab) and 51 Messier (the Great Spiral) quite satisfactory. The committee also declared the instrument perfectly fit for the work for which it was designed; that Mr. Grubb had fulfilled his contract, and that no time should be lost in packing it for Melbourne. They also added the remark, after minute examination of the excellence of the telescope and the perfection of the machinery, that Mr. Grubb had been more influenced by the desire of producing a perfect instrument than by any desire of pecuniary advantage.

Mr. Lassell presented a separate report. This gentleman having already made and mounted a 4ft. mirror, was particularly able to criticise. Of the objects already mentioned, he stated those of the greatest altitude were shown the best. The night of the 19th was cloudless, yet the air was quite unfit to test the powers of telescopes of large aperture. "Under the circumstances I considered the vision highly satisfactory, and I should anticipate that in a fine and tranquil state of the atmosphere the performance will justify very sanguine expectations. Uranus was accompanied by two satellites, which were, indeed, more conspicuous than I expected to see them. In conclusion, I freely express my opinion that the entire instrument is a great triumph of mechanical engineering and optical skill."

Yet the Cape Astronomer again wrote: "I am not satisfied with the performance of this great instrument, and I do not think the mirrors are at all perfect in figure. I have not yet seen anything like good definition of a planet with the lowest power (220). Of course, we get plenty of light even with the Nebulæ; but no definition with bright objects."

It appears several things happened to mar the fine definition accomplished by Mr. Grubb in Dublin.

1. The big mirror (A) had been grievously mismanaged. Instead of naphtha, or the strongest alcohol, being applied to dissolve out the whole of the lac varnish, a weak alcohol* was used, which only dissolved the resinous portion of the lac, leaving an intractable film of wax, which rapidly deteriorated the polish and optical performance.

2. The small convex was re-polished by an inexperienced hand, which would assuredly ruin the delicate hyperbolic figure, and it was, most likely, badly adjusted.

3. A black annulus was applied to it.

4. The eye-stop was considerably deranged.

In September the mirror became almost useless, and the second mirror (B) was substituted for it. With this were two small convexes (*a*) (*b*); the performance with (*b*), untouched by the polisher, was excellent. On March 31, 1870, the report from Melbourne was: "Mirror (B) performs very much better, and the telescope will now, doubtless, compare favourably with others of its class and dimensions. . . What has been done unmistakably shows that it is capable of grasping the work for which it was originally intended."

A slight error was detected in the mirror B—a cruciform image given to the star when used with the convex (*a*) repolished at Melbourne. The most scrupulous care is absolutely necessary in supporting a mirror on a polishing machine so as to avoid all uneven strain, so that the figure may be equally perfect when it is removed. Besides this, there is no evidence that the complicated system of balls and levers for supporting the big mirror was ever properly examined or adjusted.

(On one occasion, when I first mounted my Cassegrain, a blade of grass, on a hill about a mile off, appeared double. It took some laborious trials to detect the cause—a slight strain on the large mirror.)

Mr. Le Sueur stated this stellar cross was not permanent, showing inequality of strain.

Well, after all this painful revelation, the gentlemen most directly responsible for the character and quality of the monster glass were greatly moved to defend their original opinion. First, and foremost, Dr. Robinson, of Armagh:

"As for Mr. Le Sueur's doubt regarding the figures of the speculum A, and the small mirror which he regarded as jointly affected with spherical aberration, I remark that he himself had seen many difficult test objects with that speculum in Dublin, and he was present when the remarkably clean and sharp discs of large stars were shown. . . . . A piece was cut out of the large speculum, which Mr. Grubb polished and varnished; the varnish was perfectly removed leaving no trace whatever, and no mealy appearance. If Mr. Le Sueur had provided himself with a quantity of fine carded cotton and absolute alcohol, and, soaking rolls of the cotton in the spirit, had gone patiently and carefully over the surface, it seems very probable he would have obtained a white and brilliant surface.* In any case, the use of water was quite improper. If the yellow stain be tarnish, it might yet be removed by rubbing with slices of lemon, provided no lac be present."

There remains another consideration—Temperature. A mirror, especially a metallic one, performs with the greatest *éclát* only when used at the same temperature at which it was originally finished. Now, even in a glass mirror, a very few degrees change the figure and spoils its best performance. What, then, must happen at Melbourne, where very often the temperature varies 50° in a day and night? The expansion would tend to convert a parabolic into a hyperbolic figure! It would seem desirable, therefore, to figure such mirrors at the mean temperature of the site. Sir J. Herschel suggested muffling the large mirror up with thick blanketing just before sunrise, and stuffing the hollow front with woollen mattresses to keep off that terrible temperature of 130° in the day time. It was covered over with a sliding zinc roof, forming, I should think, a perfect oven at times. The accounts of the performance of metallic reflectors are so far instructive as to show the only true conditions of definition. Sir W. Herschel wrote a good deal about the performance of his reflectors under different atmospheric conditions:

"Oct. 10, 1780 (6h. 30min.): Having just brought out my telescope, it will not act well. A quarter of an hour afterwards it performed well; half an hour's exposure improved it." He deduces the following principle: "That, in order to see well with telescopes, it is required that the temperature of the atmosphere and mirror should be uniform and the air fraught with moisture; either a frost after mild weather, or a thaw after frost will derange the performance till either the frost or mild weather is sufficiently settled that the temperature of the mirror may accommodate itself to that of the air."

Mr. Browning has persistently declared a wooden observatory inimical to the performance of reflectors, and that if its air is even two or three degrees above the outer air, the mirror will not show its best definition to perfection.

Dr. Robinson's dictum, that the pupil of the eye in man does not exceed one-fifth of an inch, requires confirmation. When an observatory has been carefully darkened for viewing nebulæ, I have observed the pupils of visitors under a dim light greatly larger than this, expanded to the utmost limits permitted by the *iris*. And in viewing faint nebulæ, this is expanded marvellously—almost like those of the owl or cat in the dark; but as soon as the light brightens it contracts, and in some persons appears never to exceed the one-tenth of an inch!

---

* Methylated spirit.

* In the Feb. number of *Monthly Notices* of R.A.S., Mr. Lassell states he removed lac varnish perfectly after eight years, and that brilliancy was perfect.

One of my friends is endowed with the most marvellous keenness of sight I have ever witnessed. After a time viewing the great cluster in Hercules, he exclaimed: "I see the stars right up to the very centre!" Then he proceeds to count those in the streamers. On another occasion he sees about 20 stars in the centre space of the Ring Nebulæ in Lyra, besides a crowd of stars edging it and scattered through it. It is evident the pupil of his eye goes on expanding, and gets more and more sensitive with gazing. It is the same with the microscope. He describes irregularities in the celebrated lines of the *Amphipleura pellucida*, as shown by Powell's new $\frac{1}{12}$th. invisible to most people. A dim light thus gives great advantage, by allowing the pupil to expand, which enables the retina to engage a larger pencil of rays. The black spot, seen in the emergent pencil of a low eyepiece, is extremely inconvenient when excessively large. Inadvertently, I gave Mr. Calver an order for a 6in. Newtonian of 24in. focus with a 2in. Kellner; the black spot assumed a portentous diameter. It was a miniature of the flat reduced only twelve times, whilst the diameter of the full pencil was exactly ½in., and what a Cyclops eye it would require to embrace such a beam of light. The telescope with this low power was darker than a small *finder*. With a deep eyepiece of ¼in. magnifying 96 times the light *increased*, the black spot minimising to insignificance, and the emergence 6 ÷ 96 = $\frac{1}{16}$in. The eye then easily embraced the whole pencil. With a 1in. eyepiece the pencil became one quarter broad, and on a faint object the eye would take in the whole light.

In designing the great Melbourne Cassegrain the Astronomer Royal for Ireland expended laborious thought and calculation. His first object was to produce a pencil with the lowest power capable of entering the eye. For this purpose the small convex was so chosen as to be the least possible to intercept all the rays from the big mirror (48in.), and the most exquisite figuring was demanedd to reproduce an enlarged image formed by the big mirror when enlarged from 5 to 6 times at the final image, independent of the eyepiece.

| The focus of the field lens of eyepiece | 16in. |
| " " small convex ...... | 74·71in. |
| " " eye lens............ | 3·2in. |
| " " parabolic mirror.... | 30½ft.* |
| The aperture in this was............ | 8·05in. |
| Distance of surface of convex to focus F of parabolic.............. | 61·0in. |
| Distance of focus F from focus of convex.......................... | 13·71in. |

This result 13·71in. is the value of $x$ insisted upon in previous articles.

$$\text{Field of view in general nearly} = \frac{\text{Cotang. } 1'}{\text{mag. power}}$$

$$= \frac{3438}{220} = 15\tfrac{1}{2}' \text{ (minutes).}$$

Or about half of the moon's disc.

The diameter of the emergent pencil is easily calculated. With 220 its size is exactly 1-220th of the big mirror, or 1-220th of 48in., which is ·022″, or a circle slightly exceeding 1-5th of an inch, whilst the black spot, which is the image of the hole in the mirror 8·05, is just about the 1-27th of an inch, which reduces the area of the emergent pencil to nearly 1-6th of an inch.

In the paper composed by Dr. Robinson no datum is given as to the focus of the lowest eyepiece. It may, however, be calculated from the formula already given in these articles.

Thus magnifying power M is connected with the great focus F, and the convex focus $f$ by an equation involving the focal length E of the eyepiece; so that—

$$M = \frac{F}{E}\left(\frac{F}{f} + 1\right) = \frac{366}{E}\left(\frac{366}{74 \cdot 71} + 1\right)$$

Or—

$$220 = \frac{366}{E} \times 5 \cdot 1.$$

Hence—

$$E = \frac{366}{220} \times 5 \cdot 1 = 8\tfrac{3}{8}\text{in. (nearly).}$$

This eyespot is a very important factor in distinct vision. In my Cassegrain it was a constant source of trouble and annoyance, for unless centricity were secured, so that the black spot was exactly central, the definition was marred. It never seemed long to maintain its normal position. Sliding eye-stops were at last applied. Our valued and experienced correspondent, "Prismatique," seems painfully alive to this glaring fact.

In the next article I propose to deal with this point.

---

* 30½ft. = 366in.

## THE INTERNATIONAL INVENTIONS EXHIBITION.—XIV.

### Cutlery, Ironmongery, &c.

GROUP XXIV., located in the West Quadrant, is devoted to cutlery, ironmongery, &c., but the "etcetera" covers a rather wide range, for surgical appliances and dentists' materials are included. Perhaps the most interesting exhibit in connection with cutlery is the "forge" of Mappin and Webb, in the South Promenade, where the processes of forging, grinding, and hafting table-knives are to be seen. Such an exhibit could not be located in the buildings; but it is a mistake, to say the least, not to have catalogued it in the group devoted to cutlery, for it is practically the only exhibit in the branch which has much interest for visitors. The skilful manner in which the workers hammer out knife blades from the red hot steel rods is worth seeing, for it shows what can be done by the trained eye and hand in shaping a piece of metal, and repeating the operation as often as required, the pieces being almost exact in their similarity. Some surgical instruments of course come under the head of cutlery, and that perhaps accounts for their being placed in this group; but they are not of much interest to those outside the profession, and not a few of the other exhibits connected with this branch fail to attract attention from the absence of information in the circulars or descriptions supplied by the exhibitors. For instance, it is not easy to understand what connection Dr. Wright's pulmonic candles have with "cutlery, ironmongery, &c.," but we suppose they come under the "etcetera." Still, even then we are at a loss to know why they are exhibited, for though we gather from the circular that Eucalyptus enters into their composition, it is singular that the printed reports of four "professors" and the quoted opinions of the medical papers omit the very particulars which are required in an exhibition of inventions. Dr. Wright also shows an instrument for the production of "spray," which appears to be simple and efficient, and to consist of a small air-pump easily worked by the thumb pressing on a spring plunger. Turning, however, to the exhibits which properly belong to the process, we note some fine samples of decoration on tin-plate by Mr. H. Rees, of Bolingbrooke-villas, Wandsworth-common, S.W. The effects that can be produced by the method of "crystallising" the tin on these plates are well known; but Mr. Rees has gone beyond the simple processes, and shows what can be done in making tin-plate ornamental. Mr. Clark, of Oxford-street, exhibits a collection of "clippers" and hand shearing tools, which are tolerably well known by this time as useful appliances in the stable and garden, if few have adopted the hair-cutter and beard and whisker-trimming device. They are efficient tools, whether applied to horses, sheep, or grass lawns, and the shaving and hair-cutting modifications may also find patrons. The principle consists in making one blade slide over the other, both having cutting teeth. Mr. John Tyson, of Pleasant-street, Liverpool, shows a useful tool (portable) for facing up the flanges of steam pipes; but why it is located in this group it would probably puzzle the officials to explain. A cone bearing supports the pedestal from the interior of the pipe, and a tool fixed in a revolving arm faces up the flange. It is not wanted in the shop; but it will be found useful at sea and in places where machine tools are not available: Lieut.-Col. Hartshorne, Eaton-terrace, S.W., shows an ingenious combined tool, which is made by Hill and Son, of the Haymarket, and which will commend itself to all who have any experience of camping out or "roughing it," as it is termed. The Americans are celebrated (in a way) for combination tools; but this tool can, we think, take the first place, for it contains a hammer, a hatchet, wire nippers, a saw, which when put at right angles serves as a T-square, a 12in. rule, which also forms a straightedge, four files of different degrees of cut, a pair of compasses, screwdriver and crowbar—in short, it is a *multum in parvo*, weighing 2¾lb., and a tool that every traveller or sojourner in out-of-the-way places would find useful. Jelley, Son, and Jones, Blackfriars-road, S.E., show sash fasteners, locks for railway doors, and an improved slipping hook for horse harness. This safety-link is of the jointed pattern, the hinged end bedding into the neck, where it is held by a collar having a sort of bayonet fastening. A quarter-turn of this collar releases the hinged part of the link, which at once opens out and frees the pole-chain or other portion of the harness. Chubb and Sons' Lock and Safe Company, Queen Victoria-street, have a fine collection of their well-known locks, and a door fitted with their new push-and-pull arrangement. In this case the handle does not revolve, but on pulling it a lever acts on the bolt and turns it within the frame of the lock. The door closes with the slightest push. Mr. G. Plumpton, of Warrington, exhibits his patent gasfitters' combined pliers and screwing tackle, comprising screwing stock, dies, taps, reamers, tap wrench, wire-cutter, tube-cutter and shaver, turnscrew, widener, &c., the separate pieces fitting into or between the handles of the improved pliers, and saving the gas-fitter the trouble of carrying about several rather heavy and cumbrous tools. Kaye and Sons, of High Holborn, exhibit a collection of locks, noticeable amongst which is their patent frictionless mortise latch with a lever lock. The latch, without a lock, can be let into a door ¾in. thick by boring a hole ⅜in. in diameter to take the tube in which the spindle is placed. The catch itself is in the striking-plate, and when the door is closed, it revolves quickly into a hollow in the face of the lock, and holds the door firmly. When the handle is turned it presses the spindle in the tube, which pushes the catch from its hold by an almost frictionless action. Another novelty shown by the Messrs. Kaye is their patent economiser watering pot, which is fitted with a valve and spindle on the principle applied to engineers' oil-cans, so that the flow of water is stopped directly the thumb is removed from the button. The shape is neat and handy, and the improved watering-pot will be appreciated in greenhouses and other places where plants are closely arranged. E. and J. M. Verity, High Holborn, exhibit their N. M. T. ("no more trouble") blind action, which requires no rack or fastening for the cord. The bracket carries two little pulleys above, and slightly on each side of the pulley on the roller; over these pulleys the cord passes and under the roller pulley, consequently a pull on either side of the cord lifts the roller off the break, and it revolves with the minimum of friction. As soon as the cord is released the roller drops on the break and the blind is held in the position desired. An automatic looking-glass pivot consists of a wedge-shaped piece on the pillar, and a fitting to match on the frame, so that the weight of the glass keeps it in any position to which it may be placed. Messrs. Verity also exhibit the Heli-spherical Chimney Terminal, designed apparently to impart a spiral motion to the smoke, and by receiving the wind at an angle of 45° to obtain more or less of an exhaust motion. Melhuish and Sons, of Fetter-lane, E.C., besides a large collection of useful tools and cabinet brassfoundry, exhibit a novelty in Elliot's pneumatic door check, which consists of a piston working in a cylinder, and connected by links to the door. As the latter is opened, the air is compressed in the cylinder, and consequently acts as a spring to close the door, while slamming is prevented by the resistance offered to the return motion of the piston. The patent stair-rod eye will commend itself to housewives. It consists of an ordinary eye, or something similar, and a cover of brass perforated to allow the rod to pass through the eye. When the stairs require cleaning or painting, the eye-covers are removed, and the dirty appearance which the ordinary fixed eyes soon present is avoided. The patent knocker-bell consists of a bell with a pivoted hammer, operated by a spindle passing through the door and the boss or anvil of the knocker. For each knock there is also a ring. The arrangement can be adapted to any knocker. Mr. W. Pike, of the Albion Hotel, Lanark, exhibits his patent alarm bell door knob, in which any attempt to turn the handle outside causes the bell to ring. The bell is fitted to the inner handle, and does not ring when the door is opened from the inside, while it seems to be impossible to tamper with it, so as to prevent it ringing. The arrangement is applicable to till drawers, cupboards, &c. Castors, locks, and sash fastenings present the chief features of novelty in this group. The Patent Ball Castor Company, Upper Thames-street, E.C., exhibit Box's device, in which the ball is made of chilled iron, polished. Mr. Jones, of Duke-street, Chester, exhibits an improved globe castor, in which the upper surface of the ball bears against a number of steel balls placed in an annular groove. Mr. A. C. Fountaine, 3, Bennett-street, Fitzroy-square, W., exhibits a patent frictionless castor for furniture and machinery, which resembles the old style in external appearance, but is provided inside with strong bearing plates and three or more small steel balls, thus giving perfect freedom of motion under the heaviest weights. Douglas and Co., of Queenhithe, E.C., exhibit their patent springless locks and night latches with small keys. We referred to these locks, as applied to railway-carriage doors on p. 293, but in the simplest arrangement a weight is used instead of a spring to keep the bolt or catch out. Douglas's patent mortise-lock is actuated by pulling, pushing, or turning the handle, the spindle having a twist which acts as a quick-thread screw. The arrangement adopted for railway-door latches and locks by the one movement,—the mere swinging-to of the door being sufficient. Mr. W. White, F.S.A., of Wimpole-street, W., exhibits a springless lock, also acting by means of a weight. The handles are hollow, and are held to the spindle by a nut placed inside, the knob having a movable portion to enable the nut to be screwed home. Mr. W. A. Gill, Arthur-street West, also exhibits patent lock furniture, in which the knobs are screwed on the spindle, and prevented from turning back by a key which slips over the spindle and on to a stud. The key is prevented from slipping off by the rose. Amongst other exhibits deserving notice is a patent double-action lever lock and key, by Mr. J. H. King, Linthorpe-road, Middlesbrough, in which there are levers above and below the bolt, and the key is, so to speak, double, and must move both sets of levers into position before the bolt can be shifted. Mr. C. S. P. Wood, of Birmingham, exhibits a safe containing his patent improvements; it is said to be wedge, drill, and fire-proof, and is fitted with a lock which, judging by the key, has two sets of levers, both of which must be brought into proper position before the bolt can be shot. Mr. W. J. McCormack, of Paignton, shows his improvements in stocks and dies, in which the dies are cut at the ends of short cylindrical rods, which are driven towards the centre or withdrawn by means of a nut with a flange working on the stock. There are four dies, and the nut works two on each side, so that screws of different dimensions can be cut by adjusting the dies. Mr. Boyd, of Southampton, exhibits his patent forged screws from $\frac{1}{2}$in. diameter up to the largest size required for ship-building. These forged screws have been proved by Lloyd's test to have an increase in holding power of 50 per cent., and they are well adapted for ship-building in wood, for fastening rails to sleepers, &c. It may be mentioned that they are largely used by the Government, and Sir W. G. Armstrong and Co. Mr. W. Morley, Walmer-road, Plumstead, S.E., exhibits his patent nuts, bolts, and washers as applied to models. For instance, one bolt of an eccentric strap carries a washer with a rib on the bottom face let into the underlying surface of the strap, thus making it rigid. In the upper part of the washer is a locking-pin, which turns up into one of the grooves of the nut after it is screwed up tight. When the nut attempts to get slack, it forces the locking-pin against the shoulder of the washer, which acts as a dead stop. Amongst the sash-fasteners attention should be specially directed to that exhibited by Mr. F. Lea, of Buckingham-street, Strand, in which the lever is made to bring over a shield plate as the fastening is made. This shield is a real protection against the burglar's knife, because the lever can be turned nearly half-way home before it begins to move the shield back. There are a number of other "inventions" of more or less interest in this group, for instance, the automatic fastener of Leake, Barnett, and Co., Arthur-street, W.C., in which a little tongue catches into suitable slots in the door frame, a device which can be arranged either vertically or horizontally; the gas soldering iron of G. W. Wilkinson, St. Mary Abbott's-terrace, W., in which the copper bit is heated by an atmospheric burner, the heat of which is regulated by the pressure or supply of the gas; and the method of locking the boards of washing, wringing, and mangling machines, patented by the Standard Manufacturing Company, of Derby. By this arrangement the boards are locked in position when in use, and when the machine is not wanted they are turned up against the rollers and again locked, thus avoiding accidents to fingers and preserving the rollers. This duplex locking arrangement will be usefully applied in other directions. Mingled with the exhibits in this group are several stands containing surgical appliances,—the stand of Mr. J. W. Cousins, of Portsmouth, for instance, being specially deserving of notice for the number of inventions displayed, though they are chiefly of interest to the profession.

---

# THE AMATEUR WORKSHOP.—X.

## Planing Machines.—Cross Slide, &c.

FIGS. 94, 95, 96 give views of the cross slide of our small machine, suitable for self-acting motion in the horizontal traverse only. If it were desired to make the vertical feed self-acting also, the slide would have to be widened to take in the extra spindle with its bevel wheels, as we shall show when we come to talk about tool boxes. This second motion is seldom introduced into machines so small as this. In the figures the lugs, *a*, *a*, take the tightening bolts, which pass through the slots in the vertical slide (Figs. 94, 95) for setting the slide steadily in position while the tool is cutting. In the larger machines, screws whose heads are sunk below the slide faces are employed in preference to those passing through lugs. The strips, *b*, *b*, steady the slide in its vertical movements, and the slight swell, *c* (Fig. 95), at the back is for the purpose of increasing its rigidity.

The *pattern* of the slide is shown in section (Fig. 97), and is so simple that a few notes relative thereto will be sufficient.

In the first place, then, piece A, prepared to 2ft. $3\frac{1}{4}$in. by $4\frac{3}{8}$in. by $\frac{7}{8}$in., forms the basis of our work. Upon it we screw piece B, 2ft. $3\frac{1}{4}$in. by $1\frac{7}{16}$in. by $1\frac{3}{4}$in., and piece C, 2ft. $3\frac{1}{4}$in. by $1\frac{7}{16}$in. by 2in. (the reader will, by comparing the pattern dimensions with those of the finished slide on Figs. 95 and 96, observe as we go along where planing allowances are made). These dimensions, $1\frac{3}{4}$in. and 2in., include the hollow on the inside of the pattern. Piece E is prepared to the section, Fig. 98, piece F to the section of Fig. 99, and both skewered on. The hollows and the recesses and the rebated portion in piece A are then planed through from end to end with rebate and round planes. Two end pieces, G (Figs. 94, 97), $1\frac{7}{8}$in. thick by $1\frac{1}{2}$in. wide, are fitted and fastened in.

Upon the back, two thin strips, 6in. by $2\frac{3}{4}$in. by $\frac{1}{8}$in., are fastened, their inner edges being set at a distance of $17\frac{1}{4}$in. from the centre line (Figs. 97, 100). These are to form the sliding faces, which move on the vertical guides. Two angle guide strips to Fig. 101 are fastened within the facings (Figs. 95, 100, *b*, *b*), and the swell piece, C, to the cross section of Fig. 97, in its central portion, but rounded off to nothing at the ends, occupies that portion of the back which lies between the guide strips. The four lugs to Fig. 100 will be fastened on, but no holes cast in them. Two facings (Fig. 100), each measuring 2in. by 2in. by $\frac{1}{8}$in., will be attached to the back of the slide, flush with the ends to receive the lugs or nuts for the elevating screws. A shade of taper should be given to all edges in the direction of the front face.

The pattern of the distance bar will be formed of three sides and two ends (Figs. 94, 95), all tapered $\frac{1}{32}$in. on their inner faces. The length of the pattern body, that is, measuring over the plain ends will be $17\frac{1}{4}$in., but on these ends four chipping strips, $\frac{1}{2}$in. by $\frac{1}{8}$in., will be attached, those next the curved edges alone being skewered on. The curved edges have a lighter appearance than edges left quite straight.

I have shown mitre wheels for moving the elevating screws. Of course, they are not necessarily mitres; in fact, in heavy machines wheels of unequal size are always used, giving gain in power,—to overcome the difficulty of moving cross slides weighing ten or fifteen hundredweight. In the heaviest machines of all, a couple or three combinations of bevel gear are used to overcome the resistance of the weight and the friction, the first pair of wheels being moved by a hand wheel placed within comfortable reach of a man standing on the ground, while a spindle passes diagonally from these to the wheels at the head of the vertical slides. Belt pulleys at the ends of the cross spindle are also employed, but are unsatisfactory in their action, owing to the frequent slip of the belt.

In regard to our particular machine I should say:—Use the gearing which is procurable with least expense and trouble, whether it be mitre or unequal bevel, remembering only that the bearings must be modified to suit the wheels. If no wheel castings are readily accessible, and a pattern must be made, use mitres as drawn, because one pattern will then answer for the pair. The wheel figured here is suitable for the slide it has to lift, and is made as follows:—

Draw out the wheel in section to full size to the dimensions of Fig. 102, and make three thin templets in wood (Figs. 103, 104, 105) from that full-sized drawing. By means of these templets turn a block of dry mahogany to the sectional outline, embracing the extreme dimensions measured over the outsides of the teeth, so that these will be cut from the solid block. The face marked A and the teeth faces B will be turned at the first chucking, and the inner pitch line will be run round to $2\frac{1}{8}$in. diameter, and the line also representing the tooth roots to $1\frac{7}{8}$in. diameter. A shallow recess $\frac{1}{2}$in. in diameter bored in the centre of the face A, will serve to chuck the pattern the second time, while the back C is turned to the templet (Fig. 105) and the actual pitch line, $3\frac{3}{8}$in. bare in diameter, and the root line, $3\frac{1}{8}$in. diameter, put on.

Divide the larger pitch diameter into 18 parts = the tooth centres. Project two of these points of equal division radially to the edges by means of lines passing through double bisecting radii struck equidistantly from centres measured to an equal distance on opposite sides of those points and cutting the pitch line (Fig. 106). Carry the lines so obtained in the same way up the tooth points and over to the smaller diameter until they cut the pitch line there. Thus we shall have two pitch centres radiating truly from the common focus or centre of the wheel, and by starting from the points so projected over, we can divide out the smaller pitch circle into 18 equal parts. The thicknesses of the teeth are then marked upon their larger and smaller ends, shown to full size in Fig. 102, and their curves are struck by the radii and from the centres there given. Where the striking point falls outside the circle of the teeth, as happens in the case of the root radius, a block of wood is fitted to the sweep of the tooth points and slid round, and the centre for the divider leg rests upon that. The instructions given relative to the working of tooth flanks in article VI. p. 160, will apply to these also, except that by reason of these being bevelled, a little more care is needed to ensure accurate results. A boss will be screwed upon the back of the wheel $1\frac{7}{8}$in. in diameter by $\frac{3}{8}$in. thick. I should not put a core print on for the central hole, but drill it in the lathe through solid metal.

The cross slide will weigh 62lb., the stretcher bar 15lb., and the four mitre wheels 9lb., and a fair price would be from 12s. to 14s. per cwt.

Having the castings, the first thing to do will be to make a fit between the stretcher ends and the facings prepared for their reception. (Fig. 94.) This will be readily accomplished since we have the small surfaces only of the chipping strips to work upon. These will be brought to such dimensions that the slots in the vertical slides for the tightening bolts shall be quite parallel with one another. If these have been cast in accurately, the stretcher would finish to $17\frac{3}{8}$in. and the facings would stand $\frac{1}{16}$in. above the sides of the plate. The stretcher rests at each end also upon the joggles *f* (Fig. 94), and one $\frac{3}{8}$in. stud (Figs. 94 and 95), in each end will hold the parts together.

If the slots in the vertical slides are not so true

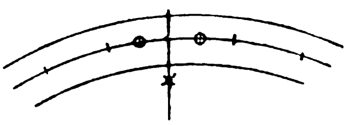

FIG. 106.

as they should be—if, for instance, the cores have curved slightly in the length, or have dropped a little, or if the surfaces are rough and lumpy in places, they must be brought parallel and true by filing, the measurement being taken across from slot to slot with a strip of wood, while the actual width of the slots themselves is checked with a gauged bit of metal slid along within them. The facing at the back (Fig. 95) *e* will be roughly filed up parallel with the front face.

Next after this, the cross slide will be chipped and filed over. Take the working face on which the tool-box slides first of all, and get that straight and free from winding. The V'd edges, worked to templates similar to those drawn on p. 554, Figs. 30, 31, of the last volume, will follow next, and the ends of the slide will also be filed square. Afterwards, the sliding-faces on the back will be filed parallel to a distance of 2¼in. from the face. The backs of the lugs are continuous with these faces, and are therefore filed flat and true at the same time, to insure their close bedding on the slides, without which good fitting the lugs are liable to become pinched off when being tightened up. The guiding edges *b*, are also brought to a good fit, with the narrow strips *g* cast upon the vertical slides. According to our design, these guides should measure 17⅜in. over when finished, and the strips *g* on the slides should work up to 1⁄16in. thick, in order to be this distance apart.

Care must be taken to keep them parallel, not only with each other, but also with the slots for the tightening bolts.

The cross slide should now be set in place, and with a bent scriber, the width of the slots be marked upon the backs of the lugs, and a hole drilled in the centre of each lug—in the one direction about 7¾in. centres—and with edges corresponding in the other direction with these scribed lines. Make four bolts to the dimensions of Fig. 107, and put the cross-slide temporarily in place. Their nuts are made thin—½in.—purposely, to allow the tool-box to slide in front of them.

The bevel gearing will now engage our attention. The two wheels marked A (Figs. 94 and 108), will be bored to ¾in., and the two marked B to 1in. From the pitch line to the back of the boss, the wheels A will, when faced, measure 1⅛in., and the wheels B 1⅜in. A keyway ¼in. by ⅛in. will be filed in each. The horizontal spindle, Fig. 94, will be turned from a piece of wrought bar to ¾in. diameter, two flats for keys filed in positions to correspond with the keyways on the wheels, and one end filed square to take the winding handle.

The elevating screws, Fig. 94, would be better if made of steel, but wrought iron is commonly employed. By adopting the right and left-handed arrangement of wheels shown in the figure, right and left-handed screws are rendered necessary. But if the wheels are put both right or both left-handed, both screws will be right-handed. The threads should number four or five to the inch, no advantage being gained by having fine threads, but rather the contrary, since in the tool-box itself we have the means of exact adjustment. The collars *h*, *h*, Figs. 94 and 108, are for the purpose of preventing any upward thrust of the screws, with consequent injury to the wheel teeth if the cross-slide happens to get tight through non-slackening of the bolts, or other accidental hitch occurring. They are slipped on after the screws are put in place, and the set pins keep them in position.

I have drawn the screws square-threaded, as they are in manufacturers' machines. But many who do not possess a screw-cutting lathe, and who would rather that the work were all their own, could cut V-threaded screws with stock and dies, which, if not quite the orthodox thing, would answer the purpose, and would last as long as the amateur himself. A thread of this length could be cut in sectional portions of three or four inches at a time by the exercise of a little patience.

Fig. 109 shows how the hood bearings may be attached to the tops of the screws, so that they can be fitted up in preference to those on Fig. 108, if so desired. The top lug is omitted from the pattern in that case. The bottom of the bearing A is prolonged, and becomes a bush within the crown wheel. The crown wheel is kept in place on its spindle by a pin, *a*, driven through both boss and spindle, while the prolongation of the hood-bearing is grooved circularly to receive a set-pin, *b*, taking into it from the wheel boss, so that while the wheel is free to revolve around the stem of the bearing, the latter cannot move up or down upon the head of the screw. The wheels on the horizontal spindle are kept in place by set screws.

Lastly, there are the lugs, (Figs. 94 and 100, *i*,) which are the nuts for the elevating screws. These I prefer to make of wrought iron, separately from the slide, rather than as a portion of the casting itself. A ¼in. screw, ¾in. long, tapped into the centre of the facing pieces, Fig. 110, will hold them securely. As the chances are against their standing square when screwed up in place, the filing of the facings affords a readier means of adjustment than the turning back of the shoulders at the termination of the threads. When the nuts stand square in place, the centres of the elevating screws will be obtained either by measurement or by levelling up carefully and dropping a taper pointed plumb bob down from the centres of the screw lugs in the vertical guides. When the centres are marked, remove the nuts to the lathe for drilling and screwing.

## VENTILATION AND LIGHTING OF COAL-MINES.

THE recent explosions in coal-mines have drawn renewed attention to the old questions of improved means of lighting and ventilating the workings. The present system of ventilation may be briefly described as drawing air through the workings, and not a few writers on the subject have pointed out that the method is radically wrong. Given the area of the workings, it is an easy matter to calculate how much air must be drawn through them to keep the atmosphere in a breathable and safe condition—provided only that the amount of gas yielded by the working face is known; but that is just where the difficulty arises, for no coal-mine in the world always gives off the same amount of gas in any specified time. The differences in the pressure of the atmosphere indicated by the fluctuations of the barometer materially affect the quantity of fire-damp given off from the face, but the most serious difficulty is the sudden outburst of pent-up volumes of gas when released by the action of the miner's pick. "Blowers" have ever been a sore trouble to the miner, for if they do nothing more they frequently extinguish his lamp; but, unfortunately, they too often produce all the conditions necessary for an explosion. Ventilation by suction is no remedy; we require the plenum method—a pressure of air always maintained in the workings, whatever may be the atmospheric pressure. Col. Shakespear has recently in our columns and elsewhere called attention to this matter, and, as it is now conceded that no lamp yet devised is altogether safe in the presence of "blowers," it remains to be considered what can be done by working coal-mines on the pressure system of ventilation. As Col. Shakespear points out, ventilation by suction is mischievous, because the current travels in lines from point to point like a running stream, omitting bays, sides, crevices, and the like, which harbour accumulations of gas as creeks do water. Now the real and true check to colliery explosions is by delivering air under pressure at the face of the coal, which would expand, and, penetrating all parts of the mine, make its escape up both or either of the shafts. How that is to be done in the best manner is for experts to determine; the one objection to it is the extra cost, but it may be doubted whether that need be so great as has been assumed. In the one case we have an exhaust fan at the up-cast, drawing air through the workings; in the other it would be necessary to lead the air by pipes to the face of the coal, and consequently the delivery ends would need frequent shifting. Another matter of great importance is the use of gunpowder in "shot-firing." It may be considered that some seams of coal are difficult to break down, and cannot even be worked with commercial success unless some economical method of breaking down the coal and stone is available; but there cannot be much doubt that coal-dust is a potent factor in explosions, and that whenever a "shot" is fired in dusty mines there is great risk of a disaster. Hence it should be insisted upon that whenever blasting operations are to be carried on, all the "roads" in the vicinity of the "shot" should be thoroughly watered, and the "shots" themselves so arranged as to produce the minimum of flame. Faraday and Sir C. Lyell in 1844 drew attention to the risk of spreading explosions in consequence of the presence of coal-dust, but little has been done, and the only radical remedy seems to be to prohibit the use of any agent which produces a flame for the purpose of breaking down coal. The lime cartridge was thought to have solved the difficulty, and it certainly is most efficient in some mines, but at present it has not found much favour with miners. With safe "blasting," safe lighting, and pressure ventilation, explosions in coal-mines ought to be very rare, if they happened at all—though there is always the ever present danger of the surreptitious match. There seems to be a tendency to imagine that electricity will provide a safe means of lighting coal-mines, even the distant workings; but it would be a great mistake if colliery owners were compelled to adopt that method. Mr. Sydney F. Walker, who has had considerable experience with the electric light in mines, and is not likely to have any sentimental objection to its use, pertinently says there are grave practical difficulties in the way of the use of the electric light at the working face, where it would be of most service, both from the additional light given and from the greater need of a safety-lamp at that point. The working face is constantly moving (in one method of working ever receding), and the operation of getting the coal in its most marketable form entails the constant falling or shattering of huge masses, so that no fixed lamp would be of the least service or could live long. On the other hand, up to the present, so far as he is aware, no portable electric lamp giving a good light for the time required has been produced which is of a reasonable weight and size, so that the collier can handle it and place it in position where his light is most required. By reducing the amount of light on the one hand, and its duration on the other, a few so-called mining electric lamps have been produced; but they would be useless for practical mining work, as they only last a few hours at the outside, while their cost is out of all proportion to that of the existing forms of lamp. In his opinion, the outcome of electric lighting in mines for the working face will be that supply mains will be led to convenient points near, and the collier will attach a pair of small wires to them and his lamp to the other end of his small wires, and use it as he likes. Main leads or wires seem the most feasible plan, but, as every electrician knows, the great difficulty is that on making and breaking contact a spark passes, and the electric spark is of such a temperature that it will inevitably fire any explosive gas in its vicinity. Several collieries have their shaft bottoms and main roads lighted by electricity, but the difficulty of using incandescent lamps at the working face is the risk of sparking when contact is made or broken. If the pressure system of ventilation were adopted, and adopted so thoroughly that explosive mixtures could never form, electric lighting in mines would, we believe supplant the whole race of safety-lamps, but at present the use of incandescent lamps would involve the risk of firing the gas at the working face, and in suitable conditions of causing an explosion. Compulsory legislation is, however, to be deprecated, for, as Mr. Walker says, if the electric light and other forms of electrical energy are to be utilised, as we hope, in mines, factories, and our homes, it will only be after having won their way in a fair field, and not under the wing of any grandmotherly legislation. The early progress of new inventions, more particularly electrical, is too often seriously retarded by inefficiency, arising from their promoters either not knowing or not fully appreciating the difficulties they have to contend with; and in his opinion compulsory legislation would greatly increase the chances of such inefficiency, with the result that the law would either be repealed or become a dead letter.

## STABILITY AND SPEED OF VESSELS.

### A Problem in Mechanics.

THE following paper by Mr. F. J. Patten has been written in view of the forthcoming contest for the *America* Cup, and will be read with interest by all yachtsmen and builders of models. It is from the *Scientific American Supplement*:—

The various requirements of use have given rise in water craft to the trial of nearly every form of floating body, each possessing qualifications designed to serve a certain purpose, and generally gained at the expense of a corresponding loss in points equally important for another. In view of the great variety of shape that still prevails, it is at once apparent that in order to arrive at definite conclusions regarding a particular feature, such as a boat's stability regarded as a floating body, or its speed as a moving one, the discussion must necessarily be confined to a comparatively small class of the same general type. In the class selected for our consideration, we observe that certain incentives in the construction of this small class alone have led to great variety, both in rig and model, determined not only by the results desired, but in a great measure by the individual ideas of the mechanic or builder as to what particular arrangement of parts would seem most conducive to the desired end, whether speed, stability, sea-going qualities, or room; and even while having the same results in view, we still witness an apparently endless struggle for supremacy between two varieties of the same class. They are diametrically opposed in principle, and will be at once recognised as the broad and shallow boat on the one hand and the narrow and deep craft on the other.

Let us endeavour to analyse this problem from a purely theoretical standpoint, and ascertain what theory teaches of practical value concerning the respective merits of these two species of the same general class of sailing craft. Let us see if the pure mechanics of the problem point to any practical advantage that one may possess over the other, and to what particular end that advantage is most conducive. To make the investigation intelligent and logical it will be necessary to consider, first, the simple mechanical principles involved, and deduce the results to which they point, comparing them with practice or the observed results of experience. It should be a matter of interest with every gentleman who sails a yacht to known and understand, as far as exact knowledge may go, the action and result of the different forces he makes subservient to his pleasure; and while there is perhaps no more complicated problem than a definite statement of every successive cause and effect that results in the flying yacht, still a consideration of the principal forces at work, and how they may be rendered most effective, is not only within the bounds of possibility, but is also comparatively simple, and equally within the reach of the mechanic who builds, the yachtsman who sails, and the physicist who investigates the forces of nature. Concerning both the shallow and deep draught boat much has been written, but it is perhaps safe to say that little has been written from a standpoint sufficiently general to be thoroughly impartial; for if not advocating one side of the disputed question to the extreme prejudice of the other, then perhaps, with the view of reaching a certain class of readers, the treatment has been so popular as to be wanting in thoroughness, or, on the other hand, from the standpoint of the physicist all practical considerations have been overlooked. It will be our purpose to address the general reader, while it is also proposed to view this question in the simple light of a problem of mechanics, and ascertain what may be learned from an analytical yet, if possible, a strictly practical consideration of the subject. To avoid the error incident to a confusion of terms, as well as a misconception of the principles involved, it will be necessary to begin our inquiry with the pure mechanics of the subject, and endeavour to obtain, first of all, clear ideas as to the meaning of certain technical expressions in common use as well as the theoretical and practical value of the quantities they represent. To do this let us first suppose a body in a fluid of greater relative specific gravity, which is the physical condition of any vessel afloat in the water. In the simple case chosen there are forces at work whose united and resultant action, as in all cases, determines the position the body will assume, first with respect to the surface of the water or "plane of flotation," and, second, with respect to its own "axes" and "planes of symmetry," meaning those lines and planes in a body about which its mass is evenly balanced. In practice the vertical plane passing through the stem and stern post is a plane of symmetry, because the mass of the vessel, in any position, is evenly distributed and balanced with respect to it, and in practice it is the only plane of symmetry the vessel contains. The position which the body finally acquires in the water, when left to itself undisturbed by any external forces, is one of equilibrium, or rest; and this position, under the circumstances named, is in practice obtained where the plane of symmetry of the vessel is vertical, at right angles to the plane of flotation, and the centre of gravity of the entire mass is at the lowest possible point. In such a simple case, which is that of any vessel afloat and at rest in the water, certain forces are at work which must be in equilibrium among themselves, or else motion would ensue until a position of rest were reached. As will be seen later, there are various positions of equilibrium, resulting, however, from the action of an external force or the resultant action of many of them, which, together with the first mentioned, bring about a new position of equilibrium. Neglecting for the present any external force, a vessel at rest in the water as described is acted upon by its own weight, a force directed vertically downward through the centre of gravity of its entire mass. This force will be recognised at once as the entire weight of the vessel, including everything in or upon it.

A reaction against the downward force results. It is the upward thrust of the displaced water, just equal in amount to the entire weight of the floating vessel, and contrary in direction. This upward force is known as the "buoyant effort," and results from the displacement of the water by the vessel settling down into it until a point is reached where the "buoyant effort" is just equal and contrary to the weight of the vessel. In this assumed position of rest these two forces are the only ones at work: they are equal in intensity and contrary in direction; holding each other in equilibrium, they produce rest.

The intensities, points of application, and directions of these two forces under different circumstances determine the question of equilibrium or resulting position of all floating bodies. The forces for discussion will then be:—

First.—The weight of the vessel. It is necessarily constant in quantity; its intensity remains always the same, and comprises not only the weight of the hull, but everything in or upon it, masts, spars, rigging, and sails, as well as movable cargo. The point of application of this force, or the point where it acts and its effort is felt, is the centre of gravity of the entire mass. Its direction is vertically downward through this point. The force is therefore known, and its effect may be ascertained, for all its elements are given. No matter what the position of the vessel, this force remains invariable in its intensity, direction, and point of application.

Second.—The "buoyant effort." The action of the water to support a body wholly or partly immersed in it is called the "buoyant effort." It acts simultaneously with the first-mentioned force; is just equal to it in intensity and contrary in direction, acting upward. Like the first, its intensity is always constant, because it is always equal to the weight of the displacement water—*i.e.*, the weight of a volume or bulk of water corresponding exactly in shape and size to the submerged portion of the vessel, and comprising a quantity of water, in whatever position the vessel may assume, just equal in weight to the weight of the entire vessel with everything in or upon it, and is commonly known and described as the vessel's "displacement." The point of application of this force, however, or the point in the vessel at which it acts, is variable in position, which is very important, for this point moves with every motion of the vessel from side to side of the plane of symmetry, but its position can always be ascertained from any given position of the vessel. All this will be clear from a consideration of the nature of this force. It is always the upward thrust of the displaced water, and, therefore, acts vertically upward through the centre of volume or figure of the water displaced, or, what is the same thing, through the centre of of volume of the submerged portion of the vessel, which, of course, changes as the vessel in rolling or careening submerges more of the hull on one side of the plane of symmetry, and removes from the water a corresponding amount (in volume) on the other. It will be clear, however, that as this amount of displaced water must always be the same in weight at all times, the submerged part of the vessel must always be the same in volume or bulk, no matter what its position or configuration. This point, the centre of volume of displaced water, will, it is evident, never coincide with the centre of gravity of the vessel, but will always be above it, below, or to one side, as the vessel changes constantly from one position to another in rolling about or pitching, and thereby changing the configuration and shape of the submerged part. For any given position of the vessel, however, the point through which the buoyant efforts acts can be determined with close approximation.

The second force may therefore be regarded as known, its intensity, direction, and point of application being given. The point, variable in position, through which this second force acts is called the "centre of buoyancy," being the point through which the buoyant effort acts. The two forces considered being in fact but a single one, the weight of the vessel and the consequent upward reaction the water opposes to it are the only original forces at work in the system—*i.e.*, in the floating vessel regarded as an independent system of forces. Left thus alone, they produce equilibrium, and the vessel floats at rest. If the vessel is now subjected to the action of any external force, or many of them, the equilibrium of the first two is at once destroyed, another force is introduced into the system which compounds itself with the first two, and a new position of rest, one in which all three forces are in equilibrium among themselves, must result. It is this second or new position of equilibrium, the determining circumstances of which are of practical value. We have, then, a third force external to the system of vessel and water which acts upon it combining itself with the forces considered, and producing results dependent entirely upon the new conditions. In practice there are generally a variety of external forces that affect the vessel, but they all have a single resultant, which may be found and treated as a single external force, thus giving definite data to the problem. A moment's consideration of the subject will show that of all the external forces that may affect the position of a vessel in the water, there is always one in practice—the action of the wind—compared with which all others are insignificant in value. For instance, it affects but little the careening force of the wind for a man to walk from one side of a good-sized yacht to the other, or how comparatively little does the sudden shock of a wave to windward affect this force. (No reference is here made, of course, to little sailing tubs and cat boats, in which the smallest forces at work compare in magnitude with the larger ones that determine the boat's stability.)

The external force, then, for our consideration at present will be regarded as the assumed resultant action of the wind upon the entire sail area. Its point of application will be at the "centre of effort" of that area. The force will be assumed to act parallel to the horizon; but should it not, it could be resolved into components, horizontal and inclined, of greater or less relative value according to the inclination of the sails and the direction of the wind with respect to their surface (assumed flat). This horizontal component, in most cases the actual force of the wind, careens the yacht, while the inclined one acts parallel to the surface of the sails, and its effect is lost. This third or external force completes all those involved; others, of course, arise, but their action is comparatively insignificant. The point of application of this external force is known. Its intensity is also known, being so many pounds pressure to the square foot of sail exposed, depending upon the velocity of the wind, and directed at a certain inclination to the sail area. To simplify the discussion, its direction will be assumed horizontal and at right angles to the longer axis of the vessel, or practically abeam. No matter what direction the wind comes from with respect to the vessel, it will have such a component, susceptible of measure with greater or less approximation; and it is this component whose action when combined with the other two it is desired to investigate and ascertain what new conditions of equilibrium arise and what arrangement of the first two forces is best calculated to meet and resist the action of the third. The foregoing statement of the forces and principles involved is perfectly general in character and equally applicable to all cases, and must determine the position under given circumstances of any vessel afloat, whatever its shape, size, or mass. The question of the relative stability of two yachts consists, then, in the determination of the resultant or ultimate action of all the forces at work, internal or external, under the same circumstances for each. The question involves also in a measure the determination of how, under given circumstances, the action of any external force, as the wind, may be best met and resisted, or used, by the combined action of the known interior forces at work. The external force will, of course, have to be assumed. It is necessarily the resultant of several, each of which depends for its direction and intensity upon a variety of data, which can only be approximated in value.

(*To be continued*).

## PHOTOGRAPHY AND THE SPECTROSCOPE.—I.[*]

By Capt. Abney.

EVERY lecturer, when he begins, must have a text of some description, and I propose to make my text for the lectures a plate exposed to the spectrum. You see before you a spectroscope comprising a collimator, two prisms, and a camera, with a lens of 13in. focal length, and in this slide is a sensitive collodion plate.

The spectrum of the hot carbons of the electric light is upon the focussing screen which you see before you, and I will simply expose this plate, and refer to it from time to time as my lecture continues.

The plate is given six seconds' exposure to the light of that spectrum, and now in the subdued light coming from this lantern, whose sides are covered with translucent orange paper, I see the picture is coming out under the action of the ferrous oxalate developer. After fixing, we see that we have the photographed spectrum on the plate.

This is the text on which I have to hang my lectures. We have three things to consider. First of all, we have got the light, then we have the apparatus, and then the sensitive material on which the spectrum is taken. The white light from the carbon poles, in passing through the apparatus, is spread out into a coloured band, which we call the spectrum; and the spectrum has effected a change in the sensitive salt of silver, as is shown by the blackening on the application of what is called a developer. The cause of the change in the sensitive material is what I first address myself to.

To conceive a right notion of photographic action we must first of all conceive, in the most elementary manner, the structure of matter. The structure is beyond our actual visual acquaintance, but we may be able to visualise it from the way it behaves; we have to draw our conclusion about it from evidence of an experimental nature. What we want to get is a mental picture of matter. Physicists have come to the conclusion that homogeneous matter is composed of molecules, or small masses which are altogether similar one to another—*i.e.*, they have the same composition. In different matter these molecules have different weights. Further, it is believed that the molecules, or the small particles of matter, are themselves composed of atoms, which we take to be the fundamental unit of matter. Now, from experimental data, Sir William Thomson and others have come to conclusions as to the limits of the size of these molecules, and also as to their distribution in space. From the kinetic theory of gases, it is concluded that the diameter of a molecule lies somewhere between one twenty-five millionth part of an inch and one two hundred and fifty millionth part of an inch. Further, in gases it is conceived that the molecules are free to move in straight lines in any direction, the direction being altered only when the molecules collide; that is to say, when they strike one against another. In a liquid, the particles are bonded much more closely together, and the free path of the molecules is very much shorter. That is to say, that they cannot go from one place to another without very much more frequently coming into contact with other molecules; and the molecules pass from place to place at a very much slower rate than they do in gases. A solid, such as is our silver salt, is conceived to be such that the molecule has no free path, but is confined in a limited space in which it can oscillate, moving round a mean centre. As to the distribution of these molecules in liquids and solids, Sir William Thomson has arrived at very definite conclusions also. In a lecture at the Royal Institution, he said that he concludes that in every ordinary liquid, or transparent solid, or seemingly opaque solid, the mean distances between contiguous particles is less than one twelve millionth of an inch, and more than one two thousand five hundred millionth part of an inch. These are big figures, but still the distance apart is very small. "To form a conception of this," he says, "imagine a globe of water as large as an ordinary football to be magnified to the size of the earth, each constituent molecule being similarly magnified. The magnified structure would be more coarse grained than a heap of small shot, but probably less coarse grained than a heap of footballs." So you see that, by magnifying to this extent, you have a coarse-grainedness which, of course, is only relatively coarse grained after such an enormous magnification. Or you may put it in a different sense. If you magnify eight thousand diameters by an ordinary microscope—and that is about the limit to which a microscope will magnify—and if you magnify that eight thousand diameters again eight thousand times, you would be able to see the molecular structure of water. So much, then, for molecules. We will now turn to the atoms. These will not bear such a very large disproportion of size to the molecules as do the molecules to the smallest visible particles. We must, however, I think, conceive that every atom (and this is an important point) is charged with energy very much in the same way that the magnet is charged; only, instead of two poles, as a magnet has, each atom has only one pole. It is unipolar.

---

[*] The substance of the Cantor Lectures delivered before the Society of Arts.

Now, suppose that this energy is something like electrical energy. We know that positive repels positive, and that negative repels negative. And, further, we know that the positive energy will attract what is called negative energy; and if the two be exactly equal when they combine, of course there will be a neutral state. But in the case of the atoms of matter, circumstantial evidence tells us that the amount of electrical energy which is upon a given atom of matter—if you like to put it in that way—is never the same as it is upon another atom of matter; that is to say, there is always a surplus of one over the other. Thus we may have an atom charged with what we may call plus 2 of energy, and another one charged with minus 1 of energy. Those two atoms, on coming together, give you a result of energy of plus 1, and this would again be capable of attracting another atom of matter which was charged with a negative energy, and so on. From chemical considerations, it would appear that plus and minus energies of different atoms, as I have said before, are never exact multiples of one another, and that when they are bonded together there is always an excess one over the other. A good example of the energy of the combination of atoms together may be shown by the combination between a gas, chlorine, which we have here, and the metal antimony, and you will see that when the latter, as powder, is thrown into the former the two combine with an evolution of heat, showing that a vast amount of energy is given out. The chlorine and the antimony form chloride of antimony; that is to say, five atoms of chlorine and one of antimony. You see the evolution of heat between those two; so much, in fact, that the chloride of antimony, as it was formed, was at a perfectly bright white heat. The case immediately before us is the silver salt. Let us experiment with that in a similar way. Into the chlorine I will throw some powdered silver, and I wish you to notice the difference between the results in the two cases. You see that the combination between the silver and the chlorine only produces a red heat, whereas antimony produced a white heat. In other words, the combination between antimony and chlorine is much more vigorous than the combination between silver and chlorine. If you had to separate the atoms of chlorine from those of the antimony, you would have to use very much greater force than if you had to separate the atoms of silver from the atoms of chlorine.

When two electrified bodies attract one another, they attract one another inversely as the square of the distance. That is to say, if there is a distance of one foot between them, they attract one another with a force of, say, 1. If they are 2ft. from one another, they only attract one another with a quarter that amount. Supposing atoms attracted one another according to the same law, then of course, they being so very close to one another, the attraction would be considerably greater than if they were visibly apart. But besides this attraction between atoms comprised in the molecules, there also seems to be a repulsive action, into which I will not enter more fully now, because that would be almost beside my subject; but I may say that besides the atoms attracting one another (we will take chloride of silver for instance) when they get within a certain distance of one another, they repel one another, and so there is a continual oscillation between the atoms composing those molecules.

In this circular glass trough of water is floating a little magnet, the magnet being held at the surface of the water by a cork. Passing round this coil, which is large enough to surround the trough, is an electric current from three Grove cells, and if I place it round the cell which contains the little magnet, and not quite on a level with the water, you will find that the single magnet goes into the centre of the water. It is repelled from the sides by the current that is floating round that wire. Well, now, we have here one magnet. Suppose I put another magnet in. The ends attached to the cork have poles of the same name. They repel one another to a certain extent, and yet the force from outside makes them go as near one another as possible. By moving this coil vertically we can make them separate and oscillate, and we can picture to ourselves the way in which two atoms in a molecule may oscillate, and be attracted, and yet repelled one from another. I put another little magnet in, so now there are three; and here, perhaps, we have a picture of chloride of silver, which I say is composed of one atom of silver and two atoms of chlorine. We can still make them vibrate and oscillate. Here we have a mental picture—at least, it is a mental picture to me—of the way in which the atoms of chloride of silver may be made to oscillate. Again, I take four, and we repeat the same thing. Here we have a picture of ammonia—three atoms of hydrogen and one of nitrogen oscillating. And so I might go on. I might put five or six or a dozen in, and we might get some idea of the way in which they would all oscillate.

Here, then, we have endeavoured to draw from visible phenomena a mental picture of the way in which atoms of a molecule are vibrating. I must, however, call to your mind that those magnets are vibrating only in one plane, whereas, of course, the atoms of a molecule are vibrating, not in one plane, but in space of three dimensions.

Now we will throw a spectrum on the screen. I am now going to send the light of the lamp through this bisulphide of carbon prism, and I need scarcely say that the prism has to play an important part in spectrum photography. The wave length of the red is about one forty-thousandth of an inch, and the wave length of the violet, which is on the left of the screen, is about one fifty-seven-thousandth of an inch. Each ray of light is transmitted in air at the rate of about 190,000 miles in a second. Thus the number of vibrations of the red rays is 500 million millions, and 700 million millions in the case of the violet rays, and this rapid succession of blows batters against anything upon which they fall. The mean violet, I may say, is the photographic light *par excellence*, and we shall recollect that such rays might beat upon the sensitive salt which we expose to it 700 million million times in a second. Therefore, you see, if you give an exposure of the 100th of a second you still have seven million millions of vibrations beating on the sensitive plate, so there is ample vibration to effect any change on the molecule of silver chloride, supposing always the amplitude (or distance of swing) is sufficient. Instantaneous photography will not be complete, I suppose, until you can reduce by a million times.

We may take it that an atom vibrates somewhat in the same way that a pendulum vibrates. Here I have a very rough contrivance to show what I mean. I set the pendulum swinging. Now picture to yourself that the bob is an atom, and picture to yourself, also, a wave of light falling upon that pendulum; if the wave of light be synchronous with the pendulum, it will increase the swing, or, in other words, it will increase the amplitude of the swing of the pendulum. For a rude illustration, suppose I take puffs of my breath as illustrating the beating of the wave of light, and suppose the atom to be at rest; I begin, and I blow; every time I give a well-timed puff to that pendulum, the pendulum increases in amplitude or swing. But if my breath does not come in unison with that pendulum, you see that very soon I should bring that pendulum to rest—in other words, unless the wave of light beats in unison with the atom, the amplitude cannot be much increased. It is true that as long as the breath strikes the bob as it is going away from me, the amplitude is increased; but if the puffs are regular and slightly more rapid or slower than the pendulum oscillation, the amplitude must eventually be diminished.

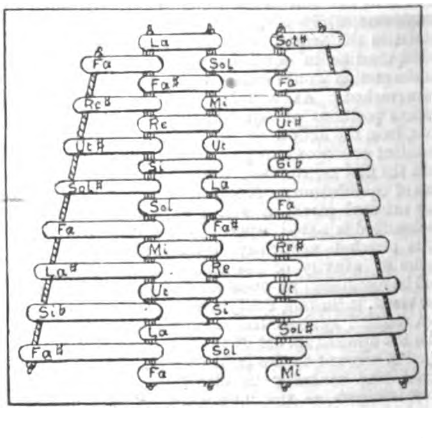
Here we are met with a difficulty, and a very great difficulty. I exposed the plate to the spectrum, and you see the blackening not only was where one wave of light synchronised with that atomic motion, but that there were a great many waves of light, extending from the ultra-violet as far as the blue which affected it. How are we to get over that? That is a difficulty which has puzzled a great many people. I would ask you again to form a mental picture of how that could possibly arise. I do not say that it is the correct way; but all I say is that you can form a picture in your own mind, can conceive of how it could be done. Here I have another pendulum, but in this case the bob is attached to an elastic band. The time of the vibration of a pendulum depends upon the length of the pendulum. Therefore, if during the time of the oscillation of the pendulum I alter the length, I also alter the rate at which the pendulum vibrates during any instant. I pull down the weight of the pendulum, and at the same time set it swinging, and you will see that during every part of this motion the length of the pendulum is altered so that a great many differently timed puffs of breath might be synchronous with the pendulum. It is not like this other rigid one, where it is of a definite length, but here the length of the pendulum keeps altering. I only ask you to form a mental picture of the way in which such a thing might happen. In this way you can picture to yourself how a molecule might vibrate, and still be synchronous with more than one vibration of light.

Proceeding another step, I may say at once that, to my mind, the theory of the photographic image is well established—that is to say, the theory as to the action of light upon molecules of silver—is as well established as, at all events, the wave theory of light itself. Now, I am going to show you an experiment which, perhaps, will help to illustrate what I mean by the vibrations of atoms. In this slide I have got a gelatine plate, and I have a little flat iron which has been made warm. It is rather too warm to be borne comfortably. Here I have a phosphorescent plate, which I propose to illuminate with magnesium wire, in order to give an even source of light; I press this flat iron against the back of the plate which is in this slide for a short time. I shall not let the plate cool; but while it is warm I will expose it to the phosphorescent light for about fifteen seconds. The plate is now allowed to become cold, and is developed. If everything has gone right, we ought to have something which shows us that the oscillations of the atoms of bromide of silver (which is the silver salt on this plate) have been given extra amplitude by the action of the heated iron to the back of the plate. I am afraid that I cannot show you the development in the light.

(*To be continued.*)

## THE XYLOPHONE.

LIKE most musical instruments, the xylophone, had its origin in very remote times. The Hebrews and Greeks had instruments from which the one of to-day was derived, although the latter has naturally undergone many transformations. Along about 1742 we find it widely in use in Sicily under the name of Xylonganum. The Russians, Cossacks, and Tartars, and especially the mountain population of the Carpathians and Ural, played much upon an instrument of the same nature that they called Diereva and Saloma.

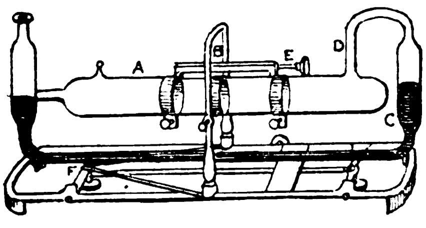


It appears that the xylophone was played in Germany as early as the beginning of the 16th century. After this epoch it was in use for quite a long period, but gradually fell into oblivion until the beginning of the present century. It was toward 1830 that the celebrated Russian Gussikow undertook a grand artistic voyage through Europe, and gained a certain renown and received many honours due to his truly original productions. Gussikow possessed a remarkable technique that permitted the musical instrument which he brought into fashion to be appreciated for all its worth.

As the name, "instrument of wood and straw," indicates, the xylophone consists of small pieces of wood of varying length, and narrow or wide according to the tone that it is desired to get from them. These pieces of wood are connected with each other by cords so as to form a triangular figure, as shown in the illustration, that may be managed without fear of displacing the parts. The whole is laid upon bands of straw designed to bring out the sounds and render them stronger and purer. The sounds are produced by striking the pieces of wood with a couple of small hammers. They are short and jerky, and, as they cannot be prolonged, nothing but pieces possessing a quick rhythm can be executed upon the instrument. Dances, marches, variations, &c, are played upon it by preference, and with the best effects. The popularity of this instrument is making rapid progress, and it is beginning to be played in orchestras in France, as it has been in America for many years. A method of using it has just been published, as well as pieces of music adapted to it, with piano, violin, orchestra, &c., accompaniment.

## A NEW FIRE-ALARM.

THE annexed figure represents an apparatus for closing the circuit of an electric fire-alarm by means of the expansion of air and the action of gravity. It consists of a glass cylinder, A, full of air, and mounted upon pivots in a frame, B, in such a way that it can tilt in one direction or the other like the beam of a balance. A glass tube, C, containing mercury is arranged parallel with the cylinder and connected with it. One of the extremities, D, of the glass tube communicates with the air chamber, so that the mercury in the column, C, of the tube rises or falls according as the pressure of the air in the cylinder, A, increases or diminishes. The position of the cylinder in the frame is variable, through the screw, E, so that the equilibrium of the system can be regulated at will.



When a fire breaks out and increases the temperature around the apparatus, the air expands in the cylinder and causes the column of mercury in C to fall; the equilibrium of the balance is destroyed, and one side of the apparatus descends until it touches the two contact springs, F. The electric circuit is thus completed, and sets in operation an electric bell or an indicator. The temperature at which the apparatus is to operate is determined beforehand, and the balance is regulated in consequence. The tubes descend with sufficient force to establish a perfect contact, provided the platinum points are clean. The apparatus returns to its normal position automatically as soon as the temperature falls and the mercurial column rises. The inventor of this apparatus is Mr. Pritchett.—*La Lumière Electrique.*

## SCREW-CUTTING ON THE ENGINE LATHE.*

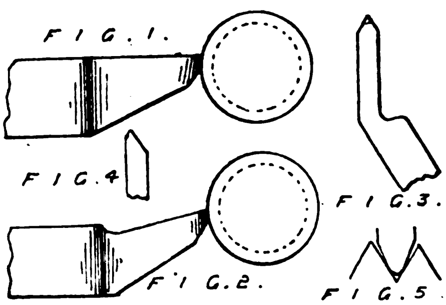
THE V-thread being that which is most frequently and generally used, the cutting of it is naturally the first to be considered. To produce a good job, a most necessary thing is to see that the piece we propose to cut is turned to the right size. To have a neat and perfect thread, it must be turned small enough to just escape coming to a full thread, and the surface should be finished reasonably smooth. If not turned small enough, and if the screw reqires to be cut still smaller after a full thread is attained, it is very sure to tear out and cut raggedly, and make a very bad-looking screw. This is especially true of cast iron, where I have sometimes seen half of the thread torn off by trying to cut beyond a full thread. If it ever happen that a thread is cut to a sharp point, and yet is not small enough, the top of the thread should be filed off before continuing the cutting.

If the screw to be cut is to be made the size of some existing screw, a pair of calipers with very broad noses covering the points of two or more threads will be found a convenience in determining the outside diameter. The screw to be cut should be turned somewhat smaller than the size indicated by these calipers, as the points of the thread swell and rise somewhat under the pressure of the tool in cutting. If the screw is to be cut accurately to any required size, it cannot be done with any certainty by these calipers, as the least difference in the sharpness and perfection of the points of the thread will affect the result.

A V-thread can be measured and cut to size more accurately by calipering the bottom or smaller diameter of the screw. The latheman should keep a pair of calipers for this purpose. The points of these calipers should be thin and V-shaped, somewhat more acute than the thread gauge, and the points should be ground off, so that they will never touch the bottom of the thread, Fig. 5. By the aid of such calipers, the expert workman should be able to cut a screw to the size of any sample screw with great nicety. It is not practicable to use the calipers with a knife-edge, and to measure the bottom of the thread, as the least imperfection in the points of either the calipers or the screw would mislead us. And, at their best, these calipers, on account of the pitch of the thread, do not represent its actual diameter, but only serve to compare it with the sample.

The difficulties in the way of a uniform and universal system of screw-threads seem practically insurmountable. The growing uniformity in the number of threads to the inch for any given size is to be rejoiced at as an approximation, but still we cannot state the actual size of any given screw in figures. We can state it, of course, just as we can state the length of a pendulum beating seconds in vacuo, and at the temperature of ice-cream, or the length of a degree of the earth's surface, and it will do us just about as much good. By the dissemination of the micrometer caliper, we are pretty well agreed as to how large an inch shall be, or any fraction of an inch; but no nicety of any measurement will enable a man to cut a 1in. screw here that shall fit a 1in. nut a thousand miles away.

From the nature of its work, the V-thread tool is the most tried of all lathe tools, and to get it right and keep it right, so far as the wearing of it is concerned, is very difficult. If you have a new sample of tool steel that you want to try, there is no better test for it than in a thread tool. If it will stand satisfactorily for that purpose, it will be good for any lathe tool. A thread tool must not be too soft, or it will wear away fast, and when worn it not only will not cut well, but the shape and correctness of the thread is immediately impaired. Upon the other hand, if the tool is too hard, the point will break, and cause great trouble in that way. The first cut over a screw is usually the most trying of all to the point of the tool, and it must not be crowded too much. It should be set so high as to leave scarcely no clearance in front of the point. This will secure to it the best possible support, and reduce the chance of breaking. At the same time, the top of the tool should be ground back to give the point as acute an angle as it will stand without breaking or dragging itself into the work. As a general thing, the sharper the tool is ground back on the top, the smoother will be the surface cut. Cutting metal, and rubbing it off, are two distinct mechanical operations.



The latter method of removing metal is employed more frequently than it should be. If the tool is raised much above the centre of the work to give it a better cut, it may be necessary to lower it by the screw at the back of the rest as the thread becomes deeper and the tool comes in nearer to the centre. If the lathe rest has no elevating screw, or other arrangement for adjusting the height of the tool after it is fastened in the tool post, then the front of the tool should be ground to stand nearly vertical, and the point set level with the centre of the screw to be cut, and to enable it to cut well and easily the top will require to be bevelled back more than if the tool were higher and with more clearance in front. Many mechanics are subjects of a little illusion—optical or otherwise—regarding the setting of a thread tool. Fig. 1 is about how I generally see a thread tool set. Fig. 2 would be condemned by half the mechanics I know, as far too rakish and piratical, and even positively dangerous. Yet the angle of the cutting face of the tool and the clearance in front of it are alike in both figures, while the advantage in other respects would seem to lie with the latter, as not requiring readjustment of height at different stages of the cut.

For general use in cutting threads, say up to six, I would use a tool not much thicker than the required thread, and usually bent to 30° to the right, Fig. 3. The bending of the tool gives it an offset, and makes more room for the rest in working up to a shoulder. There is generally but little trouble experienced from the springing of a thread tool, and for convenience of grinding and handling it is well to make it light. It is well enough to propose regrinding a thread tool by grinding the top, and so avoiding the difficulty of adjusting the V to gauge every time; but in practice it does not work well. The difficulty of making the second side of the V to gauge correctly with the first side is really no greater than that of grinding the end of a square-nosed tool true. The sides of the V are always accessible on any flat-faced grindstone or emery wheel, while if we begin to grind a little curved notch in the top of a tool to give it cut, as some still advocate, and too many still practise, we go but a little way in that direction before we encounter the impossible.

Where the thread is to be cut close up against a square shoulder, the tool should be ground away on the following side of the V until the leading side is left only just wide enough for the side of the thread to be cut, Fig. 4. Great care is required in cutting up close to a shoulder, as the tool must be withdrawn from the cut before the revolution of the screw entirely ceases. If we undertake to withdraw the tool from the cut after the lathe has stopped, we are very sure to break the tool, and not only have to re-grind it; but leave a piece of hard steel in the work upon which to repeatedly encounter similar shipwreck. In approaching a square shoulder with a thread tool, it is also well to see that no loose chips drop in between the shoulder and the advancing side of the tool. Where it can permitted, and usually it can be, a groove should be cut in the work with a round-nosed tool, for the point of the thread tool to run into, when it can be withdrawn with perfect safety. A round-nosed tool is much preferable to a square-nosed for this purpose, and leaves the work neater and stronger.

Except in the case of cutting close up to a shoulder, when the lathe should be stopped and pulled carefully up to the stopping point by hand, and at the same time the tool withdrawn from the cut just before the motion of the lathe ceases, no such careful stoppage is required; the tool can usually be withdrawn with one hand while the lathe is stopped or reversed with the other.

The angle to which it is best to grind the tool on the top for smooth and easy cutting must be determined by circumstances. It will vary with different metals, and also with different men. I pick up a tool which I know will do very satisfactory work in iron or steel, and I find the angle between the top and front to be 70’. Another tool that does very well in brass I find to be about 90°. I have used a tool in cutting copper as acute as 60°.

The stop gauge for regulating the adjustment of the tool at each cut is a convenience that will be used less and less as the workman becomes more expert. The amount the tool is fed in at each successive cut can be gauged with sufficient accuracy by noting the position of the handle upon the cross-screw. The stop gauge, I think, should only be used for the finishing cut for the purpose of producing a number of screws of the same size, and then allowance must always be made for the wear of the tool.

Taps should be cut with all the care of which the workman is capable, both in size, in the shape and inclination of the thread, and in the smoothness of the finish. When nearly cut to the size, the tool should be reground and readjusted with great care, and the thread should be cut so smooth and bright as to require no polishing after. I have a notion that polishing spoils a tap. We were using in our shop the taps of perhaps the best and most eminent American firm in that line. They were perfect in size and admirable in finish. They were, in fact, too nice. I do not know how else to explain their fatal fault. They required so much power to drive them that we were obliged to abandon their use. I verily believe that some home-made taps, rough as the tool left them, and black from the forge, would tap a hole with one-quarter the power required by these fancy taps.

In cutting threads of wrought-iron or steel, it is necessary to use some lubricating substance, and it must be confessed that for this purpose nothing is so good as oil. If the oil is not spread all over the screw, some spots being allowed to get dry, the result sought is worse than defeated. Pouring the oil upon the screw with an oil can is an extravagant and wasteful way: while using much more oil, it is not spread evenly, and the bottom of the thread, where it is most needed, is often not oiled at all. Ninety-eight and one-quarter per cent. of the machinists do it in that way. A better way is to apply the oil with a stiff, short-haired brush, like a blacking brush, and use the worst oil that you can find. I am not one of those who habitually sigh for "the good old days that are for ever past and gone, and what we never won't see no more;" but when I think of the genuine old whale oil that we used to have to cut screws with, there's where the sigh comes in, or, rather, out.

## RECTILINEAR PHOTOGRAPHS BY DISTORTING LENSES.

THIS would seem at first sight to be an anomaly. Notwithstanding this, it is not only capable of being done, but done without entailing much trouble. When a single landscape lens is employed in producing a view exceeding a very moderate angle, no defect whatever is appreciable, provided the subject be one in which there are no square marks or straight lines near the margin, as such would be represented with a greater or less amount of curvature. For landscapes or groups such single lenses, therefore, answer quite well. While we would hesitate to say that for the former purpose they are superior to any of the best compound lenses introduced for this purpose, we do not doubt they are at least equal to them. Except in the sole matter of curvature of marginal lines when overworked (by which we mean the including of too great an angle of view), the single lenses leave nothing to be desired. They work clean and with brilliancy, define well with a moderately large diaphragm, and give images sharp to the corners. When an architectural view, a map, or a chart, has been made or copied by a lens of this class, and the curvature or distortion is such as to be observable, the way to eliminate all error is to make a transparency from the negative by means of a camera with a single lens, by which an amount of distortion equalling that in the previous case is produced, the resulting photograph being absolutely rectilinear. With a transparency quite perfect as regards drawing, there is no difficulty in producing, by superposition, a negative from which all error shall be eliminated. It stands to reason that if distortion of a certain nature be produced by the use of a single lens having a diaphragm in front, distortion of an opposite nature will result from the employment of a diaphragm behind the lens. It follows, therefore, that if a view which has been distorted be returned through the lens by which it was so treated, it will, when arrested by the focusing screen, be found to be practically free from all distortion. This principle is a simple one, but it is not quite so well recognised as it ought to be. What is of importance to the photographer to know is this: that no matter how imperfect his photographic negative may be as regards curvilinear distortion, it can be cured, and that in a perfect manner.—*Photographic Times.*

# SCIENTIFIC NEWS.

THE death is announced of M. Henri Milne-Edwards, the distinguished naturalist. He was born of English parents at Bruges in 1800, and his elder brother, the eminent physiologist, having settled in Paris to study medicine, Henri joined him, practised medicine for a time, and then devoted himself to natural history. In 1838, he succeeded Cuvier in the Academy of Sciences, and from 1841 he was Professor at the Jardin des Plantes, eventually taking the place of Geoffroy St. Hilaire. He resigned the chair of physiology in 1876, when his son Alphonse was appointed to it. He was President of the French Scientific Association, and published a large number of scientific works, the Royal Society list giving the titles of over 100 memoirs and treatises.

There is too much reason to fear that Mr. F. A. Gower, the inventor of the Gower-Bell telephone, whose experiments with balloons we recently mentioned, has met with an untimely fate. He made a successful balloon trip across the Channel in June, and continued his experiments in France, where he met with a slight mishap while awaiting an opportunity of returning in a balloon to England. Undeterred by this, he made an ascent on the 18th of July from Cherbourg, and since that date nothing definite is known of his whereabouts. A pilot balloon which he had previously despatched has been found and sent on to Hythe; and a balloon has been picked up without a car some 30 miles off Dieppe. It has been announced in some quarters that the unfortunate gentleman, after floating for many hours at sea, died from cold and hunger; but we believe that nothing definite is known as to his fate.

Mr. Robert F. Fairlie died on the 31st ult. in the fifty-fifth year of his age. His double-ended and double-bogie engines, known as Fairlie engines, have done good work, especially in Russia, Peru, Mexico, Canada, and New Zealand; but unfortunately his system was never carried out in its entirety. A few years ago, Mr. Fairlie made a trip to Venezuela to report on the construction of a system of railways on his plan for that country; but unfortunately was attacked by sunstroke and jungle fever, and had a long illness, from which he never really recovered.

Observations of Barnard's comet made at Nice by M. Charlois have been published in the *Comptes Rendus*. On July 11th the nucleus was found to be of the 10½ magnitude; it was surrounded by a slight nebulosity of confused appearance, about 1·5′ in diameter. MM. Thollon and Perrotin examined the comet spectroscopically on the 13th and 15th; the nucleus gave a very faint continuous spectrum, over which the ordinary-cometary bands could be momentarily distinguished. It appears that if the comet is not likely to be of much interest from its shape or brilliancy, it will still be notable on account of the greatness of its perihelion distance, which is much greater than was at first computed.

The report of the technological examinations of the City and Guilds Institute shows an increase in the number of students as compared with the previous year (3968—3635), and what is more satisfactory, an increased percentage of passes (2168—1829). The number of centres has been increased to 167 (three more); but the subjects of examination were 42 only as compared with 43 last year. The proportion of failures is, however, still much too large—45·3 per cent.—and shows that there is either a lack of teaching power, or that candidates come up who are really not acquainted with their subjects. The total cost of this year's examinations is £3,495, or a little less than 11s. per student, and it is expected that about 750 of this year's successful candidates will gain a full technological certificate by having also "passed" in science.

An object of considerable interest to engineers and power-users is now in full work at the Inventions. It is to be found in the middle court, and is called the Balanced Float Water Motor. The inventor, Mr. Sealy-Allin, claims 90 per cent. efficiency, and asks for tests. According to Molesworth, a water-pressure engine returns 80 per cent., a turbine 70, an overshot wheel 68, and a Poncelet's undershot wheel 60, and those figures are proved by experiments to be almost absolutely correct, although some trials of turbines are said to have shown more than 80 per cent. return. There will be more to say about this Balanced Float Water-Motor before the exhibition closes, as its endless chains and feathering floats not only promise long life, but the least waste in friction that can be hoped for.

The annual meeting of the National Fish Culture Association was held at the Aquarium, Inventions Exhibition, South Kensington, last week. The council reported that satisfactory financial arrangements had been concluded with the executive of the International Inventions Exhibition. The utmost had been done to present to the public an interesting and popular collection of fish, and to secure suitable specimens collected from various parts of our coasts by special fishermen. The council have widened the sphere of operations by forming at the commencement of the present year a national fish culture establishment for the purpose of conducting practical experiments in rearing various species of Salmonidæ and coarse fish. The report was adopted and officers were appointed for the ensuing year. On the motion of the Mayor of Hull a resolution was passed asking for public support to the society.

At the annual meeting of the North of England Institute of Mining and Mechanical Engineers held on Saturday last in Newcastle, the secretary read the report of the council, in which they stated that they were giving attention to the repeated occurrence of destructive explosions in coal-mines from causes the origin of many of which it was difficult to determine. Some of these accidents have occurred in collieries where every possible care has been taken to prevent them, and in pits where the amount of gas has been very limited and the ventilation good. The theory that coal-dust may be an agent in intensifying explosions has long been before the council, and some of the experiments on its effects were made by members of the institute. These experiments were not on a sufficiently large scale, or so conclusive in their results, as might have been desired; but they were sufficient to prove that coal-dust was an element of some danger. Recently the German government have taken the matter up on a scale suited to its importance, and the experiments seem to prove that the practical danger attached to the dust only is small, and that explosions of coal-dust can only be caused by blown-out shots when the dust is in very large quantities, and lying within 15ft. of of the shot. The secretary subseqently read a translation of a paper describing the results of experiments with coal-dust at Neunkirchen. It was found that a small quantity of water was not of any use. Dust, to be rendered inoffensive, must be mixed with at least two-thirds of its weight of water. It is sufficient to damp the dust to the length of the flame caused by the shot; but as this distance, with inflammable dust and a very small quantity of gas, might reach 55·76ft. and more, it will be difficult, in practice generally, to apply water. Blown-out shots, charged with 3¼oz. of powder and stemmed with the dust of dry coal, as those from Kohlscheid and Königin Louise, have given, without dust being sprinkled and without gas, a length of flame of 31·16ft., and these were augmented to 36·08ft. with 3 per cent. of gas. In no case has it been possible to fire dust held in suspension in the gallery by means of a lamp or with a strong flame of gas, the dust only burning in the flame, with a low crackling noise, without exploding.

Berghauptmann Joseph Fleischaus, of Vienna, has been appointed by the Austrian Government as president of a permanent commission for investigation into the causes of fire-damp explosions in collieries, their ventilation, the use of gunpowder in blasting, and other causes leading to the loss of human life in mining.

According to the *Photographic News*, the retina of the living eye has been photographed by Mr. Webster and Mr. Jackman, of Coggeshall, Essex. The negative was an extra sensitive gelatine plate. The crystalline lens of the eye and a 2in. focus achromatic meniscus formed one composite optical system for projecting the image, and owing to the non-actinic colour of the retina an exposure of twenty minutes by gaslight was required—no small strain on the sitter, who, of course, had to look steadily at a dot during this time. The negative, although small, shows the bifurcation of the blood-vessels, and also the edge of the blind spot. Since the photograph was taken, some progress has been made as regards arrangements for future work.

Mrs. Elizabeth Thompson, of Stamford, Connecticut, not long ago gave 5,000 dollars as the nucleus of a fund to be controlled by the International Scientific Society. She has recently increased the amount to 25,000 dollars, the income of which is to be devoted to the advancement and prosecution of scientific research in its broadest sense. At their first meeting, the trustees, Dr. H. P. Bowditch, W. Minot, jun., Prof. E. C. Pickering, Gen. F. A. Walker, and (secretary) Charles S. Minot, Boston, Mass., resolved to call their trust the "Elizabeth Thompson Science Fund." The first appropriation will be made next autumn; but when the International Association is organised, the income will presumably be placed under the control of the executive of that body.

An improved life-raft has been invented and patented by Dr. Mears and Mr. Linkleter, of Tynemouth, who have built one, in which they intend to make a trip southwards along the coast as far as Dover and then cross to Calais. The raft has twin keels and an open middle, and from tests already made is a fast sailer.

Messrs. Capello and Ivens have crossed the African continent from west to east, meeting and crossing the Lualaba, Luapula, and the Chambezi.

The American Association for the Advancement of Science holds its meeting this year at Ann Arbor, Michigan, commencing August 26.

The British Association meets at Aberdeen on Sept. 9. Dr. Armstrong, president of the chemical section, has arranged for two important discussions in his department—viz.. on the determination of the molecular weights of liquid and solid bodies, and on electrolysis. A series of critical papers will be read, and several well-known authorities have promised to contribute.

M. Henri Vivarez, writing in *Cosmos*, states that silicious bronze has a conductibility comparable to that of copper, and a greater strength than that of iron. The silicium may be introduced in various proportions, the mechanical resistance varying inversely as the conductibility. In telegraphy galvanised iron wire, which weighs 155 kilogrammes per kilomètre, can be replaced by wires of silicious bronze, which weigh only 28 kilogrammes; and in telephony iron wires of 25 kilogrammes can be replaced by wires of silicious bronze, which weigh only 8·45 kilogrammes.

# LETTERS TO THE EDITOR.

[*We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.*]

*All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. Passmore Edwards.

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original." —*Montaigne's Essays.*

## TELESCOPES USED AS NIGHT GLASSES.

[24564.] — In response to "F.R.A.S.'s" invitation on page 473, I send you Prof. Holden's article for reproduction in your columns.

**H. Sadler.**

### Observations on the Light of Telescopes used as Night Glasses.

By Edward S. Holden.

(From the *American Journal of Science and Arts*, 3rd Series, Vol. XXII. p. 129.)

In the *Philosophical Transactions* for 1800, Vol. XC. p. 67, Sir William Herschel says:—"In the year 1776, when I had erected a telescope of 20ft. focal length, of the Newtonian construction, one of its effects by trial was that when towards evening, on account of darkness, the natural eye could not penetrate far into space, the telescope possessed that power sufficiently to show, by the dial of a distant church steeple, what o'clock it was, notwithstanding the naked eye could no longer see the steeple itself. Here I only speak of the penetrating power; for though it might require magnifying power to see the figures on the dial, it could require none to see the steeple."

I had long been desirous of trying this experiment with a large aperture, and made several attempts in 1874 to have the dome of the 26in. Clark refractor at Washington so arranged that a terrestrial object could be seen, but without success. I therefore took the first opportunity to try the effect of a telescope under these conditions at the Washburn Observatory, where the large equatorial commands the horizon. The most suitable object for examination was the tower of the Hospital for the Insane, which is 20,798ft. distant from the centre of the Dome.* 1" at this distance is 1·3in.; 1' is 78in.

The whole tower has an elevation of about 9' above the horizon line. In the observations which follow, the highest part (10ft. high) is spoken of as "the spire," the next (9ft.) as "the base of the spire," the next section (13ft. high) as "the cupola" or "the dome," and the remaining portion as "the tower."

The finder has an aperture of 3·50in., a field of 1° 20', and a magnifying power of 26 diameters. The refractor has an aperture of 15·56in., a field of 11·6', and a power of 195 diameters.

The following observations were made 1881, April 18, by Mr. S. W. Burnham and myself.

The whole sky was perfectly clear except a very faint bank of clouds to the west of the tower looked at. The observations were as follows (*Hn.* standing for observations made by Holden; $\beta$ for those made by Burnham):—

7h. 35m. The tower disappears to the naked eye. In the finder the spire is still plainly seen. In the 15in. the whole of the spire, ribs, dome, and many details well seen.—*Hn.*

7h. 42m.: The tower disappears to the naked eye. In the finder and telescope everything still seen.—$\beta$.

8h. 0m. 15in.: The ribs on the cupola are gone.—*Hn.* and $\beta$.

8h. 7m. Finder: The shape of the cupola is confused and uncertain.—*Hn.* and $\beta$.

8h. 14m. Finder: Pretty much the same. 15in.: The spire on top of the cupola is still plain. No one looking with the telescope would miss it.—*Hn.* and $\beta$.

8h. 17m. 15in.: The spire on top of the cupola gone.—*Hn.* I still see it.—$\beta$.

8h. 17m. Finder: All shape to the cupola is gone.—*Hn.*

8h. 21m. 15in.: Spire still seen by averted vision, not well by direct.—$\beta$.

8h. 22m. Finder: The tower is a mere black spot. 15in.: Spire is much fainter.—$\beta$.

8h. 23m. 15in.: The spire is gone, except that I can see that the outline of the cupola is not round. —$\beta$.

8h. 25m. 15in.: Spire gone.—$\beta$.

8h. 26m. Finder: Tower gone.—*Hn.*

8h. 27m. Finder: Tower and cupola gone.—$\beta$.

8h. 27m. 15in.: Tower and cupola gone.—*Hn.*

8h. 29m. 15in.: Tower has lost all shape.—$\beta$.

8h. 30m. 15in.: Tower gone.—$\beta$.

About this time the sky was dark and the horizon became clearer, as was shown by small stars becoming visible in the finder. Probably the light cloud above spoken of was dissipated.

8h. 35m. 15in.: The cupola and tower can be plainly seen as a dusky cloud with a certain shape, when the telescope is vibrated to and fro.—*Hn.* and $\beta$.

8h. 37m. 15in.: Same.—*Hn.* and $\beta$.

8h. 43m. 15in.: The cupola and tower are seen even better than before. The horizon is clearer. There is no difficulty in seeing them when the telescope is moved, and they can just be seen by direct vision.—$\beta$.

8h. 44m. Same.—*Hn.* and $\beta$.

8h. 45m. Stopped examination, as there seemed to be no prospect of losing the tower as long as the horizon remained clear. If we had lost it we should have attributed the loss to haze at the horizon. Small stars 8-9 magnitude seen in finder. They must have had an altitude of not more than 30'.

It appears to me that this confirmation of Herschel's experiments is important and worth the attention of physicists. So far as I know, there is no satisfactory explanation of the action of the ordinary Night-glass, nor of the similar effect when large apertures are used.

Washburn Observatory, Madison, May 1, 1881.

## 100 TO THE INCH OF APERTURE.

[24565.]—I think that Mr. W. P. Dodge (letter 24545, p. 475) has taken in too serious a sense a phrase that was used by me in a half-jocose manner —that of "setting optical theories at defiance." Certainly, I am satisfied with the general theories of optics, and have not the slightest intention of attacking such; but when I find statements in certain textbooks — generally copied one from another—that do not accord with my personal experience of a particular optical instrument—well, I must then express dissent from such views. In the particular case quoted, I can give no reason why a 26in. would not bear a power of 1300 on a planet as well as a 12in. would 600, save that the atmosphere prevents the use of these powers; and, further, that I suppose it is not possible to make large object-glasses so perfectly corrected as smaller ones. I believe that the power generally used on a well-known 26in. o.g. is about 400 for planetary observations; and I have had superlative views of Mars and Saturn with similar powers on comparatively small instruments. My contention was that the atmosphere had almost as much to do with magnifying power as the aperture of the telescope —within certain limits, of course—and this opinion I see no reason to abandon until I have had ocular demonstration to the contrary. But, at the same time, I do not wish to convey an impression that large apertures are therefore useless—far from it; because with equal powers the larger instrument will show the most, as we should expect. With regard to the magnification of star images Mr. D. is right, and I am wrong, the letter having been written when much pressed for time, and therefore not read over again before posting.

**W. S. Franks.**

[24566.]—My experience of high powers on telescopes, which may interest, is as follows. Several years ago, having a very good 2½in. Wray o.g., which performed very well with powers of 80 and 125, I obtained a pair of lenses from good makers to construct a more powerful eyepiece. The field lens was ¼in. diameter, and ⅜in. focus, and eyelens $\frac{1}{10}$in. diameter, and $\frac{5}{32}$in. focus, the thickness of both lenses being included in the focal length. These, when mounted ¼in. apart, formed an eyepiece but little inferior in power to a single lens of ⅛in. focus. I tried this on the 2½in. o.g., and afterwards on an equally good 2¾in., and also 3¼in., by the same maker, the result being that it was easily seen, by the softened outline of the planets and the disc of stars, that any higher power would be useless. I am now using it on my 6¼in. mirror, which certainly stands it the best, though it is but at rare intervals that the atmosphere is good enough for it to be used to any advantage. This shows bad for the 100 to the inch theory, as on all these, o.g.'s and mirror, it is but about 70 to the inch, both as measured by the spot at the eyepiece, or calculated by the old rule of dividing twice the product of the focal length of the lenses by their sum. Focal length of o.g.'s, 2½in., 35in.; 2¾in., 40in.; 3¼in., 46in. Calver mirror, 67in., all, certainly, of the best quality.

**F. T.**

## THE DAYLIGHT OCCULTATION OF ALDEBARAN.

[24567.]—Referring to Mr. Peek's remarks on the above subject, which appear in your last issue, I beg to remind him that it is of little use to have a sidereal chronometer rated by star transits so as to give the times of immersion and emersion within the decimal of a second, unless the times of immersion and emersion have been separately computed for the particular latitude and longitude of the place where the observation of the occultation is made, because the times, as calculated for places not very remote from each other, or from Greenwich, vary *very perceptibly.*

The "partially-graphic method" of computing occultations and solar eclipses is something more than a modification of "the well-known graphic method of Mr. Penrose": for, whereas by the latter method the times can seldom be calculated to within five minutes, by the former method the like results can be obtained to within thirty seconds.

But let anyone make the attempt of working out an occultation or a solar eclipse on the "partially-graphic method," and compare the time occupied in obtaining the same results by Woolhouse's or Shadwell's method, and he will be able to decide the question for himself.

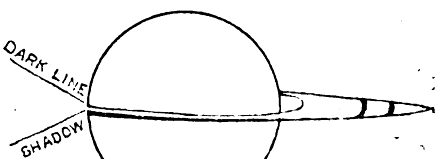
**James Pearson, M.A., F.R.A.S.**

Fleetwood Vicarage, Aug. 1.

## THE SYDNEY REFRACTOR.

[24568.]—I read in your "E. M." No. 1061, page 457, some remarks from Mr. H. Sadler about the Sydney refractor I made, and I am able to give some more particulars from the letters of Mr. H. C. Russell, Government Astronomer, Sydney, which I inclose and beg you to print them in your esteemed paper, as I think they will be of some interest.

The Sydney objective I supplied has 11⅜in. clear aperture and only 12ft. 6in. focal length. The focal length was limited by the size of the revolving dome of the Observatory. It is made of the Herschelian formula, and I supplied to Mr. H. C. Russell for this refractor the orthoscopic eyepieces for 100, 200, 400, 800 times power. According to the letters of Mr. Russell, he utilised for the most part the 400 times power; but Mr. Russell communicated in a letter of the 20th Sept., 1876, to me as follows: "I will mention one thing, and that is that I recently got a microscopic objective by Gundlach, of Berlin, ⅛in., and I tried it as an eyepiece, and though the power was 1,200 the definition was all that could be wished. Many times, in using the 800 power, I have felt that I could use a higher one." Then I supplied Mr. Russell with another set of eyepieces up to 1,500 times, and he was very pleased with that set. Mr. Russell mentioned in another letter that the 7¼in. is a Merz objective. Then Mr. Russell mentioned in the letter of 18th October, 1877, the following, about his testing the objective, that he could resolve a fine grating (which is still in my possession), at 400ft. distance with his power of 200. This very fine grating is the same as my pupil, Mr. Mellor, at Wedel, utilised for sifting the diatoms.



In the same letter of 18th October, Mr. Russell said:

"In 1874 I discovered a very fine black line along the edge of the white equatorial belt of Saturn. When I was in England I asked and no one had seen it; when I got to Washington I asked and they had not seen it. I looked myself through the 26in. and I could not see it. Now this very fine line almost exactly touches the shadow of the ring on Saturn, and a few nights ago I and another person saw both dark lines and shadow clearly, and the friend, whose eyes are sharper than mine, saw both divisions in the ring, as I have shown above; this, on the 10th of this month, when the plane of the ring almost passes through the earth."

"There is one simple test that I have often used with the glass, that may be mentioned, with a power of about 90 in the eyepiece, it will show the companion of Antares clearly *separate* from the large star."

**Dr. Hugo Schroeder.**

## PYROLOGY.

[24569.]—It is a pleasure to reason with Mr. Allen, because his arguments, independently of the gentlemanlike tone and good English in which they are expressed, are apparently directed towards the elucidation of the truth, and not, as is too often the case, towards mere controversial success. He complains (in letter 24555) that I have misquoted from his former letter the expression, "You have not proved that some of the lime was not dispersed about the bead" (of boric acid), and says "he never used any words of the kind," and that such words "are a serious perversion of his meaning." Those of your readers who have favoured us with a perusal of this discussion will remember that the words in question were quoted by me in my first letter from a private chemical communication, with the objections of which Mr. Allen says in his first letter "I fully agree"; and I therefore not unnaturally considered that, having adopted these chemical waifs so "fully," he had no intention of discarding the clothes in which they were dressed. But I am sorry to observe that the suit Mr. Allen has now put on them fits worse than before, and looks as though it had been got in a hurry from Moses and Co.; for if it be true that "chemists suspect lime to exist in a condition of solution in the clear portion of the bead" (of boric acid, which has been treated before the blowpipe), they are suspecting a chimera, for the simple reason that lime is insoluble under such conditions, both in the bead itself, B. B., and in boiling water.

---

* I have to express my thanks to Prof. J. E. Davies for the communication of the Coast Survey data from which these figures are derived.

Mr. Allen contends that all arguments derived from a pyrological view of the subject are of a circular description and an effeminate character. To obtain a fine, square, masculine basis of logic we must, according to him, consult "wet" methods of analysis alone. Now, I am sure your readers, if they are to be the umpires in this matter, will consider this *ex parte* judgment as unfair to the ladies as to myself, although I have no objection to, and on the contrary should feel flattered by, being classed mentally with some of them. For it is obvious that the reproach of "arguing in a circle" can be at least as easily and justly applied to the "wet" methods of analysis as to the "dry." The "wet" reagent for lime is, I believe, a solution of oxalic acid, and Mr. Allen apparently wishes me to test the watered solution of the bead with oxalic acid after the calcium pyroborate ball has been removed, in order to see (I write, of course, under chemical correction) if I can thus obtain a precipitate of calcium oxalate from the residual bead. If I do not, then—and then only—will Mr. Allen believe that no lime exists "in a condition of solution in the clear bead." But suppose I were, in that case, to say I was not satisfied with that proof. Suppose I were to insist on evaporating the water solution of boron trioxide to dryness; to apply the residue to a fresh bead of pure boric acid before the blowpipe; to vesiculate it, and wave the hot vesicle in the dusty air of an ordinary room. I would then show Mr. Allen, with a lens, a considerable number of calcium borate balls (derived probably from the plaster of the ceiling) contained in the very bead which he had chemically decided to be free from lime. Of course I would not thus deceive him or any one else, but merely cite an instance to show that the reliance of the pyrologist on the delicacy of his anhydrous methods is as little to be described "arguing in a circle," and as much "on the square," as the reliance of the chemist upon his "wet" methods.

I certainly "appeal to chemists," as Mr. Allen states, but it is to give my new methods a fair practical trial, which their knowledge of chemistry enables them to do better than others, and not to test anhydrous results only by those of water solutions of acids, &c., with which they have as little to do as the attraction of gravitation has with "the man in the moon."

Far from asking Mr. Allen to "abandon his processes" for these, or to "replace" with the latter "the accepted wet methods of the chemist," I am sure your readers are aware, if he is not, that all I ask him to do is to study also anhydrous analysis (not the old blowpipe methods of testing minerals with borax, &c.) as a newly-discovered branch of that beautiful and glorious science of which he is, since the publication of his classical work on "Organic Analysis," one of the most distinguished professors. I would, in fact, call his attention to some far-sighted remarks on the subject in the *Chemical Review* for July, 1884, written (as I believe) by one of the best analysts in England, Mr. J. A. Wanklyn, in a review of my last published work on the blowpipe:—"Has it ever struck any of our readers that chemistry as at present understood, with all its far reaching speculations and its splendid practical results, is after all a mere fragment? . . . Yet this bold assertion is not entirely devoid of truth. We know, to a great extent, the properties and the mutual behaviour of bodies as they exist dissolved in water. If we could find a solvent which, instead of, like water, boiling in an open vessel at 212° Fahr., required to be heated, say to 600° or 1000° Fahr. before boiling, and could we dissolve bodies in it before letting them act upon each other, it is possible, or rather probable, that we might have much, very much, both to learn and to unlearn. Still more, did we take the pains to study the mutual reactions of bodies when liquefied, not by water but by intense heat, we should find ourselves introduced into a new world. . . . The purification and extraction of metals from their ores is a very different thing from the systematic examination of the reactions of all inorganic bodies upon each other at red, yellow, or white heats. The nearest approach to such a study is made in the use of the blowpipe in chemical *analysis*." (I have italicised the last word, because the received method of blowpipe *testing* is not analysis at all, inasmuch as it does not *separate* constituents of mineral or chemical compounds one from the other):

Mr. Allen says the anhydrous system cannot claim to detect as little as 0·5 per cent. of lime in a compound. That seems rather a vague illustration; but I will tell him what he can do for himself with it in a very short space of time. He can obtain in a bead of boric acid B.B. white opaque balls of (apparently) calcium phospho-borate from the head of a fly or quarter of a grain of wheat, accompanied by a (comparatively) large quantity of combined water. He can treat in this way an ordinary healthy housefly, and then (on another bead) one which has been poisoned on arsenical paper, and observe the immense difference in results of the two flattened beads under a microscope.

Mr. Allen's logic (which would astonish the late Archbishop Whateley if it could be communicated to him through a spiritualistic medium) may be happily illustrated by another of his objections. I state that, if any one properly performs a simple operation with pure boric acid, quicklime, a blowpipe, and an assay balance, he will ascertain the *fact* that lime combines anhydrously with boron trioxide to form calcium pyroborate in the ratio of 1 : 3. Any ordinary logician would suppose that the simplest and best way to refute this statement, if it can be refuted, would be for the doubter to perform carefully several times this simple operation himself, and then to state conscientiously his average result. But Mr. Allen thinks it would be a safer, if more roundabout, way to disprove my alleged fact by means of the atomic theory (!), without having recourse to anything so hazardous as practical experimental proof. He (virtually) says that, assuming the atomic weight of Ca to be 40· of B 11· and of O 16·, the weight of molecule CaO would be 56·, and of $B_2O_3$ 70. Therefore, the number of molecules of CaO in given weight of compound divided by the number of molecules of $B_2O_3$ in the same weight $= \frac{25}{56}$ divided by $\frac{75}{70} = \frac{5}{12}$; hence, the formula of the pyrological compound is $5CaO, 12B_2O_3$—"a very improbable constitution for a definite compound." This is "fitting the foot to the shoe" with a vengeance!—a chemical "torture of the boot" worthy of the worst days of the Vatican. Considering nothing more is claimed for the atomic theory than that it is "a convenient hypothesis" assumed for the purpose of explaining the undoubted facts of the combining proportions of hydrates and of gases, which (as Prof. Dewar explained the other night at the Royal Institution) can never be kept absolutely free from hydrogen; that there is no proof whatever of the existence of indivisible atoms, but very much the other way; no absolute proof of the elementary nature of metals, but only (as almost every trustworthy work on chemistry commences by stating) that chemists have hitherto, with the means at their disposal, been unable to decompose metals into any simpler forms—considering all this, I leave it to your scientific readers to decide whether alleged physical facts, capable of such facile experimental determination, can be logically proved or disproved by the application to them of hypothetical "theories" established upon undoubted phenomena of matter under almost entirely different conditions of existence.

Perhaps, as Mr. Allen is so solicitous to show your readers the extreme delicacy of his "wet" methods of analysis, he will explain how it happened that the thousands of previous chemical analyses of cigar-ashes never detected lithia in them until the spectroscope exhibited it there in considerable quantity.

When Mr. Allen accuses me of "persisting" in only using small quantities of material for pyrological analysis, it is evident he has of late given up reading as well as contributing to the English Mechanic, otherwise he would have seen by some late articles and illustrations of apparatus in that paper that I have devised "the aluminium open furnace" to be worked with the oxyhydrogen blowpipe for this very purpose, and there is a specimen of it (made by Johnson and Matthey) among my exhibits at the "Inventions." His suggestion of "a platinum crucible" only shows that he is not yet thoroughly acquainted with the matter, for these reactions cannot be produced in that.

The last unanswered objection of Mr. Allen to the anhydrous system of analysis now left is that the results of the reactions of 5 to 8 milligrammes (weighing 20 and 32 milligrammes in this case) only are placed in the assay balance, and really, considering he "claims" in this very letter to show us 0·5 per cent. of result in his "wet" analysis, I fail to see that there is very much difference in his use of the balance and in mine, especially when we remember that the pans of an assay balance by a reputable maker are guaranteed to turn with 0·1mgr. Why, then, should there be any greater danger to delicacy of analysis in using 5·0mgr. than in using 50mgr.? It would rather appear that the constant use of large weights would, if anything, increase the friction on the fulcrum, and, therefore, any source of error. Besides, as I have before stated, you can repeat the rapid results of blowpipe analysis over and over again, and have then, at least, as reasonable grounds for taking the average result as the correct one as you would have in adopting the result of *one* long operation (perhaps occupying several days) of solution, precipitation, filtering, washing, drying, &c., in the wet way.

On the other hand, consider the immense advantage of anhydrous analysis in the hundreds of cases where the operator can only obtain a minute crystal or very small fragment, or a few filings of the mineral, or jewel, or alloy to be analysed.

**W. A. Ross.**

## EXAMINATION OF MINERALS BEFORE THE BLOWPIPE.

[24570.]—No. 11. "An alkaline aluminous silicate, with large proportion of silica and alumina, very small ditto soda, and a little lithia: greyish white, compact, very hard; "prismatic crystalline structure" (?) This description seems to tally with that of the "bisilicate" of Dana, and the "silicate" of Des Cloizeaux and Brooke and Miller—called by the first and last "spodumene"; by the French mineralogist "triphane," and by Mohs "prismatischer triphan - spath." $SiO_2$ 65·02 $Al_2O_3$ 29·14, CaO 0·50, $Li_2O$ 5·47, $Na_2O$ 0·46, $K_2O$ 0·14 (Rammelsberg).

No. 12. Like the above but not so hard, and "semitransparent" (? translucent), with less alumina than the first. Probably "petalite" $SiO_2$ 79·212, $Al_2O_3$ 17·225, $Li_2O$ 5·761 = 102·198 (Arfvedson).

No. 13. "Lepidolite," of course: from λεπις a scale, called also "Lithionglimmer" (C. Gmelin.) $SiO_2$ 46·23, $Al_2O_3$ 14·14, $Fe_2O_3$ 17·97, MgO 4·57, $Li_2O$ 4·21, $K_2O$ 4·90, F 8·10 = 100 (Gmelin).

No. 14, stated by the analyst to be "barite" or "heavyspar"; but I can only say as regards the blowpipe reactions given, that I have found "celestine" (or Strontium sulphate) to behave in much the same way with these reagents, i.e., to "hold by its sulphuric acid with great tenacity"; fragments, effervescing considerably at first—more with greater heat, but eventually declining to decompose into "transparent balls and bubbles of $SO_3$"; but Col. Ross says "this important reaction is afforded by no other mineral than barite"?

No. 15. Barium carbonate, generally called "witherite." **Mineralogist.**

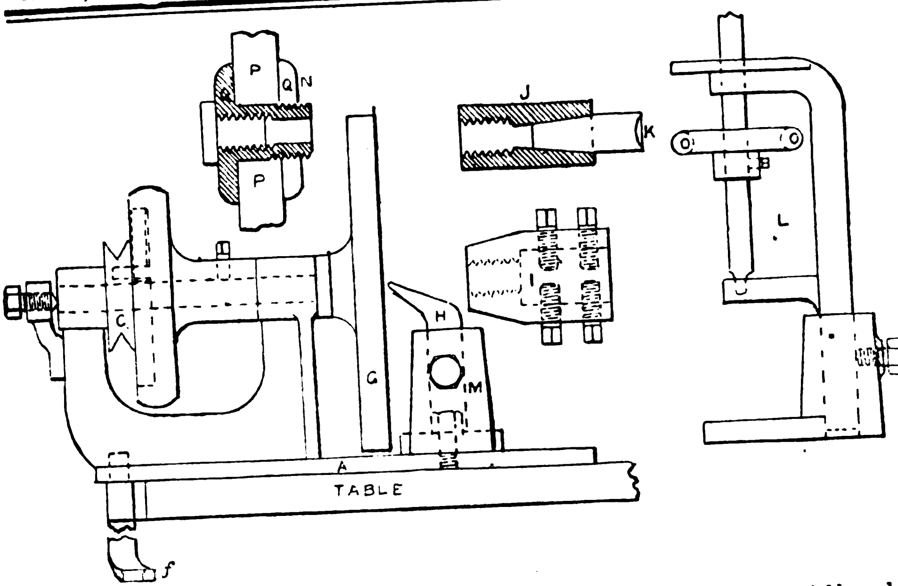
## THE OTTO BICYCLE—TO MR. BOYS, "ANTARES," AND OTHERS.

[24571.]—Happening to look over last year's "E.M.'s" a few days ago, I came on several letters on the Otto Bicycle, and am seriously thinking of getting one; but as there is no chance of seeing one out here before buying, I should like some advice from riders of the machine. What opinion has "Antares" now got of the Otto after a year's riding? At present I ride a 50in. ordinary bicycle, but the roads here are mostly too rough for it to be a pleasure to take long rides on it. Has the suggestion of having central gearing on the Otto, with chain instead of band, been carried out, and is it any improvement? I am afraid the rubber on bands would not last very long in this climate. Would it be necessary to have a stock of spare bands for this part of the world? Any advice would be very welcome to

**A South Australian Bicyclist,**

## AMATEUR LENS GRINDING.

[24572.]—I was much interested in the article which appeared in "Ours" of July 17 on lens making, and as it seemed very *nice* work, and not too difficult—in fact, just the thing for a "hobby"—I decided to "have a try," and, at the same time, it struck me that there were many besides lathe-owners who might like to do the same. I at once began to scheme a machine that should, 1st, do all the work necessary, 2nd, that could be fixed on an ordinary table, 3rd, that should not be expensive, and I now send the result. The base A is about 11in. long, and can be cramped to the corner of any table—of course, a stiff, strong table is preferable; but any one may be made stiff enough by means of a prop or two. Now, suppose the machine cramped, and we wish to start work. The end of a cord is made fast to a spring attached to eye F (spring not shown), the other end is brought up on far side of machine over wheel C, and down on the near side to within about 15in. from the floor; a stirrup or arrangement somewhat like a lathe-treadle being provided for foot to rest on, then, on treading downwards, the spindle will



revolve, and continue revolving till stopped by friction; but before it stops another tread may be given, and so the spindle kept revolving (this is effected by a noiseless friction arrangement). The speed may be altered by removing wheel C and putting a larger in its place, which can be done in half a minute. This arrangement is better than a crank motion, as the length and frequency of treads may be varied, and the foot need not follow the treadle, as when the foot is removed the stirrup or treadle will remain still, and yet the spindle keep running.

To cut the gauges, screw a piece of board on to faceplate G, face it true, screw on some sheet brass, and turn out to required radius, using rest H to support the tool. Next remove H, take off face-plate, and screw on chuck I; then, having some pieces of brass cut off, fix them one by one on chuck I by means of the screws, and turn ends to fit chuck J. (This is done to save time afterwards, as when once fitted in J they will run true without trouble.) Next take off I, screw it on J, and turn ends to gauge as at K, then proceed as in description given July 17. For large lenses the apparatus L can be fixed in M and run off faceplate by means of rubber ring O, the tool inclosed in wooden box being fixed on top of spindle.

For grinding edges of lenses a grindstone can be fixed on spindle, as shown in section at N, where P is grindstone, fixed by screwing between cheeks Q.

Mareham-le-Fen, Boston. **S. Beeching.**

## THE HISTORY OF THE TIDAL PROBLEM.—II.

(*Continued*).

[24573.]—Wallis, in A.D. 1666, in his letters to Mr. Boyle, derives the phenomena of the tides from the consideration that it is the common centre of gravity of the moon and earth, which describes an orbit round the sun while they revolve about this common centre. He, however, appears to have conjectured the principle of gravitation, though it is scarcely clear that he understood how the tides were caused by its action. These letters are published in his works, and in the "Philosophical Transactions," Volume I. page 263. He was Savilian Professor of Geometry at Oxford, and one of the first members of the scientific association which gave birth to the Royal Society. In answer to an objection which was made to him in the form of a query, "How two bodies, which have no tie, can have a common centre of gravity?" Wallis says, "It is harder to show how they have, than that they have it. That the loadstone and iron have somewhat equivalent to a tie, though we see it not yet by the effects we know. . . . . As to the present case, how the earth and moon are connected I will not undertake to show, nor is it necessary to my purpose; but that there is somewhat which does connect them, as much as what connects the loadstone and iron which it draws, is past doubt to those who allow them to be carried about the sun as one aggregate or body."

Francis Bacon, Baron of Verulam, Viscount of St. Albans, and in the reign of James I. Lord High Chancellor of England, was the most illustrious ornament of his age, and the reformer of philosophy. He was the author of a treatise "On the Flow and Ebb of the Sea"; but it must be admitted that his views on this branch of science were not characterised by the accuracy which marked his other investigations, for he conceives the phenomena of the tides to have been attributed to the moon "by common but unsupported conjecture."

To John Flamstead, who was the first Astronomer Royal at Greenwich Observatory, must be ascribed the merit of having constructed tide-tables, which professed to show the true times of high water at London Bridge for every day in the year A.D. 1683. His attention had been turned to the subject from his having frequently occasion to go to Greenwich by water.

To Sir Isaac Newton, however, belongs the glory of discovering and expounding the true theory of the tides. His theory explained with singular felicity all the prominent circumstances attending them—the difference of spring and neap tides with the effect of the moon's and sun's declination and parallax. It was about this time, also, that the Royal Society of England and the Academy of France made attempts to collect practical observations, and in A.D. 1740 prizes were offered for the best treatises on the whole subject. The treatises selected were those contributed by Euler, D'Alembert, and Bernoulli, and that of Bernoulli contained a table for computing the times of high water, which, with proper modifications, can still be used for the port of London. The modern editions of Newton's "Principia" contain a treatise by Bernoulli in Latin.

In A.D. 1774 Laplace took up the subject. Availing himself of the discoveries of D'Alembert in the theory of hydro-dynamics, he attempted to deduce from the equations of motion of fluids, the principal phenomena of the tides. The integration of these equations, however, presents great difficulties, even in the case in which the depth of the ocean is assumed to be constant, and the solid nucleus but little different from a sphere.

Finally, Laplace had recourse to the following indirect consideration—viz.: "That the state of any system in which the primitive conditions have disappeared, through the resistance which its motion encounters, is periodical with the forces which act upon it." Hence he concludes that if the system is disturbed by a periodic force, expressed by *a series of cosines of variable angles*, the height of the tide is represented by a similar series, in which the *periods* and arguments are the same, but the epochs and *coefficients* are different: This amounts to expressing the height of the tide by a series in which everything is arbitrary, except the periods of the arguments. The attention of Laplace, however, does not appear to have been directed to the construction of tide tables, for predicting the time and height of high water at any port, which is the truest test of the value of any theory.

The labours of Dr. Whewell and Sir John Lubbock furnish a large contribution to our stock of intelligence concerning the tides. By the former, an attempt was made to trace the progress of the tide into all the seas of the globe by drawing upon maps of the ocean what he calls *co-tidal lines*—*i.e.*, lines marking the co-temporaneous position of the summits of the great wave which carries high water from shore to shore. By Sir John Lubbock careful comparison was made between theory and observation, and tables were obtained for the effect of the moon's declination, parallax, and transit, as obtained from the most correct principles in the *Nautical Almanac*. By this means the *times* of high water were computed with remarkable precision; but the calculated *heights* showed discordances which this philosopher did not attempt to account for.

The tide tables first put into circulation for the port of Liverpool were those originated by the Rev. George Holden, a clergyman of Maghull, near that town, of which the theory, he tells us, was supplied by his brother, the arithmetical calculations by himself. These tables were first issued in A.D. 1770, and contained the times of high water, but not the *heights*. Subsequently, however, the heights were inserted; but the principles of the method have never been published.

Tide tables for Liverpool are also published annually in the Isle of Man, and as the calculations are performed independently, the results at times vary considerably from these of Holden.

In the *Encyclopædia Metropolitana* there is a treatise on tides and waves, which is most valuable as showing the theoretical basis on which the problem of the tides must rest. The author is Sir George Airy, the late Astronomer Royal. It discovers a ready means of disentangling some of the complicacy presented by the distribution of the times of high water in different places, and forming a sure foundation for the practical estimate of a definite part of the whole amount of retardation, when the times of spring and neap tides are better known, for all parts of the sea.

Fleetwood, July 30th.

(*To be continued.*)

## GRINDING TOOLS FOR HAYDON'S CUTTER-BAR.

[24574.]—With regard to the letter No. 24492, published in "E. M." 17th ult., the part which deals with the division of the angles, and also the section where Mr. Atkinson speaks about advancing the tool, is not very explicit; so if he kindly takes the trouble to explain them more fully, then I shall be highly obliged.

In his letter he advises to get a sheet of paper, on which to make a semicircle exactly equal to half the size of the grindstone, and then to draw a line through the centre, and to call it a starting line. He then advises to set out certain angles, and to draw some parallel lines. He then goes on to say that the intersection of the lines which bound the angles with the parallel lines will give the heights at which the tools must be ground. My difficulty lies here. In the first place, Mr. Atkinson does not mention the points through which the parallel lines must be drawn. Secondly, he has omitted to mention the principle he has followed in dividing the grindstone into certain angles, and also in getting the heights at which the tool must be held to have a certain cutting edge. I mean to say this, Why the intersection of the boundary line of the angle—say, 25½°—with the corresponding parallel line give you the edge 80° to the tool?

Again, further down, the practical example he has taken to show the application of his instructions is, I am afraid to say, not very clear. In the drawing I could not find any "x," so I could not understand that part. Moreover, where he speaks of advancing the tool he does not say whether to advance it laterally or vertically, for advancing it in either way we shall get certain angles. About reversing the tool the part is not very clear. It will be a pity if these points are left unexplained; so if Mr. Atkinson kindly takes the trouble to take another example, and explain the details of his instructions more fully, then I shall be highly obliged.

**J. D.**

## THE NEW ZEALAND RAILWAYS 3ft. 6in. GAUGE—THEIR PROGRESS AND RESULTS FOR 1884—THEIR LOCOMOTIVE PRACTICE, AND NEW DEPARTURES IN THAT DEPARTMENT.

[24575.]—I regret that illness in the first instance, and subsequently my recent visit to England, should have compelled me to suspend my contributions on the subject of the New Zealand railways. I hope to be more regular in future.

The year 1884 has been of a somewhat mixed character as regards its results in connection with the railways of New Zealand. The gross receipts were larger than those of any previous year—viz., £961,304 as compared with £953,347 for 1882-3 and £892,026 for 1881-2. But in the first place, as this was the yield of 1,395 working miles, as against 1,358 and 1,319 respectively, it does not represent so good a result proportionately to mileage, and, secondly, the working expenses absorbed 68·2 per cent. of these gross receipts, as against 52·1 and 58·6 respectively. So the net profit showed a material diminution as compared with that of preceding years. The falling off was due to imprudent reductions in the tariff of freights made in compliance with outside political pressure, and in flat defiance of the earnest warnings of all capable counsellors. The consequence has been that although the traffic has increased, so much more work has been done for so much less pay, and the revenue has suffered to such a formidable extent that the Government have been forced to reverse their injudicious policy, and it is hoped the railways will do better this year. But it is easier to do a wrong thing than to undo it. The increase in rates was resented, and ministers have paid, in extrusion from office, the penalty of their former too easy concession to improper outside pressure.

During the year 3,272,644 passengers were conveyed, also 1,700,040 tons of cargo, 686,287 cattle, sheep, &c., and 359,896 parcels, &c. The work done comprised 66,316,931 "ton-miles," at rate of working equivalent to 2·15d. per ton-mile. The rolling-stock for 1884 stood as follows:—Locomotives 218 (viz., 45 tender engines and 173 tank-engines, the latter including 4 "Fell" and 30 "Fairlie" engines, "double" and "single-boiler"), 450 passenger coaches, and 7,076 goods waggons. The employés numbered 4,839 persons.

The new engines added during the year have been mostly of the "J" class, described in former articles. They have six coupled wheels 3ft. 6in. in diameter, cylinders 14 by 20, and a leading two-wheel bogie. These engines now run most of the main-line traffic, passenger as well as goods. Indeed, the majority of trains are "mixed," and travel at a slow rate of speed. The "through" (or so-called "express") trains between Christchurch and Dunedin, which I have before described, and which may be said to be slow expresses for 140 miles, and fast stopping-trains for 90 miles, are occasionally taken by these engines. In fact, I quoted in one of my last letters, instances of their doing very good work on this duty. As a more recent illustration I might name the run from Studholme Junction to Oamaru over many gradients from 1 in 100, both ways being done at an average speed of 30 miles an hour by the express with a "J" engine. The express service is ordinarily assigned to the regular express-engines (American) of the "K" class, with cylinders 12 by 20, four-coupled wheels 4ft. diameter, and leading and trailing two-wheel bogies; but these, while doing admirably with light trains on the more level portions of the road, are not equal to heavy loads on the steeper gradients of 1 in 50 for many miles, which prevail near Dunedin, so as additional engines were needed, it was determined to take a new departure, and this was rendered the more desirable by the fact that an important line undertaken by a private company, but really an essential portion of the North Island Trunk line—no other than the first 80 miles northward from Wellington, the capital of the colony—was about to be equipped with locomotive stock of a more powerful type than any yet in use on the Government lines with which it will connect. It was deemed advisable if possible to agree upon one type of new engine, and so a consultation took place between the company's engineer (Mr. H. P. Higginson, M.I.C.E.), on the one hand, and the chief Government officials on the other, including Mr. J. Blacket, M.I.C.E., engineer-in-chief; Mr. J. P. Maxwell, A.M.I.C.E.; and the locomotive superintendent, Mr. Allison Smith, M.I.M.E., with the result that a new class of engine was agreed upon, and twelve were ordered forthwith.

The new engines will be, in point of fact, a more powerful combination of the "J" and "K" classes; or, perhaps, it would be more convenient to consider them as a development of the latter. That is to say, if we take the latter with their leading and trailing two-wheel bogies, their four coupled 4ft. driving-wheels, and their 12 × 20 cylinder, and if we insert between the two pairs of 4ft. drivers a third pair of like diameter, but unflanged, and if we add 3in. to the cylinder diameter, making it 15in., still keeping a 20in. stroke, and if further we give it proportionately increased boiler power, and a general English construction as to material and exterior, retaining the eight-wheeled double bogie tender, then we shall practically have the new type of New Zealand passenger engine. To sum up its characteristics it will be a ten-wheeled engine, six wheels coupled with leading and trailing Bissell bogies, and the following principal dimensions: Cylinders—diameter 15in., stroke, 20in.; coupled wheels, 4ft.; bogie wheels, 2ft.; heating surface about 950 sq. ft.; weight on six coupled wheels, about 24 tons; on bogies, about 10 or 11 tons; total weight, 34 to 35 tons; tender about 15 tons. These engines are expected to take heavy loads on moderate gradients easily at a speed of 45 miles an hour, and to pull the through expresses, in the long banks of 1 in 50 near Dunedin, without needing pilots.

Orders have also been sent to England for the construction of ten goods engines of the "Consolidation" class, with eight-coupled wheels, 3ft. diameter (the second and third pairs unflanged), leading Bissell bogie and cylinders 15 by 18. The six American-built engines of this description received some years ago from the Baldwin works have shown very satisfactory results so far; but while this type will be adhered to for heavy goods traffic, the English construction will be preferred, owing to its superiority, chiefly as regards the materials used for the tubes, fireboxes, and wheels.

I am still unconvinced that Mr. Fairlie's double-boiler engines have had a full and fair trial in N.Z. His single-boilers have, and are valued accordingly as among the most useful of all the numerous types now at work on N.Z. lines. But the poor double-boilers have had to contend against strong adverse prejudices, and against the still stronger adverse influences created by their having been employed under conditions never contemplated by their inventor, and eminently unfavourable to the development of their full power. That is to say, they were worked on train services which only offered light and inadequate loads, and they were not worked expansively enough. So, naturally, they did not show to advantage in the comparison of tabulated results; and when heavier loads were available, these were handed over to other engines. Therefore it is that I deem the double Fairlies rather hardly used in N.Z., and I should very much like to see some of the twelve-wheeled class (double six-coupled) tried on some of the heavy goods train services on the southern railways of this colony. But I fear that is not very probable.

The latest return of locomotive work seems to me to strengthen my contention that the double Fairlies are capable of giving much better results than many suppose. On the Hurunui-Oamaru section of the Southern Trunk Line, thirteen engines of the "J." class (above described) took an average tonnage of 125·63 per train mile: four of the "M." class (cylinders 13 by 20, six-coupled wheels, 3ft. 6in. diameter, 28 tons adhesion weight) took 104·87 tons per train mile, at a respective cost per ton mile of 0·082d for Class J, and of 0·083d for Class M. The one double Fairlie running on that section (having cylinders 9 by 16; eight wheels 3ft. 3in., double four-coupled; adhesion weight 24 tons) took 124·10 tons per train mile at a cost of only 0·075d per ton mile. These figures speak for themselves.

I may mention, before concluding this rather long letter, that another fresh type of locomotive has been introduced by the Wellington and Manawatu Railway Company, already referred to. It is a ten-wheeled tank engine, having leading and trailing Bissell bogies, six coupled 3ft. wheels (the middle pair unflanged), and cylinders 12ft. × 18ft. This engine was designed by Mr. Higginson, engineer of the line. Five of these, built by Messrs. Manning and Wardle, have already been imported, and are now employed in construction work. They are doing exceedingly well, and are likely to prove one of the most useful classes we have out here. I had a run with one a few days ago, and found it showing excellent results.

Wellington, N.Z., June 19th.

## RAILWAY-SIGNAL RETURNS.

[24576.]—MR. C. E. STRETTON, or any one who knows, would render a service by explaining or by inducing the Board of Trade to explain, through the medium of the ENGLISH MECHANIC, what is the scope and meaning of the formula at the head of the returns the companies are required to fill up. At present each company is left to interpret the directions in any way it likes, and, doubtless, each prefers to make its statements look as favourable as possible.

First, as to the heading, "Number of cases in which any passenger line is connected with or crossed on the level by 'any passenger line.'" This would be much clearer if it read "any passenger line or passenger siding' so as to make the figures include the numerous passenger sidings at the great terminal stations and the crossovers and engine sidings leading therefrom, also the passenger sidings at the larger intermediate stations. This would, no doubt, increase the number of cases immensely, and in doing so would afford a means of ascertaining to what extent interlocking had been adopted at these large stations.

Directions ought to be given as to whether a passenger "loop" line should be computed as one or two cases (I should say *two* cases); also, whether an ordinary double junction should be reckoned as one, two, or three cases.

Probably a great proportion of the "sidings" mentioned in the return are passenger sidings; and as "catches" are generally inadmissible on passenger sidings, it is misleading (as Mr. Stretton's letter, No. 24498, in your last issue shows) to include these among those sidings for which safety points are "requisite."

Goods lines and goods sidings should be included in one column, and the column for number of safety points should refer to these only.

Are "runaway" catches to be included in the return? If so, where?

There are several other points which require elucidation, but my letter is getting too lengthy.

**Coral.**

## THE PENISTONE ACCIDENT.

[24577.]—I HAVE read with surprise and regret in the Manchester papers that the action, Woodhead *v.* the M. S. and L. Ry. Co. *re* Penistone Accident, has failed. Here was a case where persons were killed in consequence of the "neglect" of the company to provide proper brakes, yet the jury do not give a verdict for plaintiff. It is a very serious matter for all railway passengers, because it proves that companies can run their trains just as they like, and when persons are killed no damages can be obtained.

I should like to ask the opinions of your railway correspondents on the matter—what do they think of the verdict? Perhaps they will go further and tell us what is "negligence," because to my mind if such a case as this does not come under that head, there never was one that does.

Here we have twenty-four persons killed and sixty-two injured through neglect to have a proper brake, and the company gets off without paying a penny! Justice, where art thou?

**Traveller.**

## RAILWAY BRAKES.

[24578.]—WOULD "Meteor," or any of your other able railway correspondents, explain the working of the Act of June, 1878, so far as it relates to brake failures? The Act says the companies are liable to a fine of £50 if they make a false return. Now, it seems the last returns come under this head. The secretary of the Railway Society has pointed this out to the Board of Trade, but they don't put the Act in action. What I want to know is what steps are necessary to be taken to put the Act in force?

**Anxious to Know.**

## FAILURES OF BRAKES.

[24579.]—LATELY there have been a large number of these failures of brakes, but I notice they have not been mentioned in your journal.

On 23rd June, the 12.55 Midland express from Bradford to London was delayed at Manningham in consequence of a vacuum-brake failure. The brake in question was not the old "leak off," but the new "ball valve" system.

On Monday, 6th July, the Midland train from London at 6.10 a.m. broke couplings in no less than three places when stopping; the vacuum brake was of two kinds, the "ball valve" and the "leak-away," and as the two don't work well in one train, there were fearful jerks, and the break-loose followed.

On 7th July, the 6.10 a.m. train from St. Pancras was fitted with "leak off" and "ball valve" brakes; the ball valve would not come off, and there were delays at Mill Hill, St. Alban's, and Harpenden.

Another serious delay was caused by the vacuum brake last week, and the cause is clearly put forward in the letter of a passenger to a newspaper as follows:—

"SIR,—I think I have a right to complain of a long delay to a Midland Scotch express on Friday last, July 24th. I left London by the 9.15 p.m. (as a rule, this train is worked with an air brake), but by great neglect on the night in question, a wrong engine, 1,328, with vacuum brake, was provided. Two or three miles after we got past Leicester we came to a stop, the vacuum brake was 'sticking' on the wheels of the front van, and the wheels were red hot; all the luggage had to be got out and put in another van they got from Leicester. This bothering vacuum brake caused the train and myself to be delayed actually *one hour and twelve minutes*. They surely ought not to use a vacuum brake on trains like the 9.15, the most important on the line. A DISGUSTED PASSENGER."

I see last week that the *Engineer*, with reference to failures, remarks that they are recorded in its columns, as they find no place in the Board of Trade Returns. Surely this shows in a very true light the incorrect way in which the returns are made out.

**Midland.**

## COMPOUND LOCOMOTIVES.

[24580.]—I WAS glad to observe the letter of "Kappa" (24549) calling attention to the very unsatisfactory performances of the above engines. More particularly would I corroborate your correspondent as to their deficiency in speed power. It will, I think, be readily admitted that engines which have such great difficulty in running at high speeds are not suitable for express passenger traffic, especially wheh the rate of speed is so high as on the L. and N.W. I will endeavour to obtain some details of the fuel burnt by these engines shortly; but I have good reason for believing that, taken as a whole, the compounds consume as much as the Precedents, if not slightly more. Considering the high pressure at which the compounds work, this result is the more disappointing.

**G. D. [illegible]**

## SPEED OF AMERICAN TRAINS.

[24581.]—WHILE the speed of English trains is being discussed in your paper, may I bring before your notice a very remarkable run made on July 9th last, on the New York West Shore and Buffalo Railway from East Buffalo Junction to Frankfort, N.Y.?

The train in question was a special, consisting of a West Shore baggage car, the W.S. General Manager's car, and a Baltimore and Ohio car, the total weight, including engine, being 292,500lb. The distance from E. Buffalo to Frankfort is 201·7 miles, and this distance, including stops, was run in exactly four hours. Deducting the 39 minutes occupied by stops, and partial stops, we get a running time of 201 minutes for the 201·7 miles, or an average speed of 60·2 miles per hour. The worst grade encountered was 30ft. to the mile, from Oneida Castle east for seven miles. Two engines were employed in this run—Engine 45, Charles Smith, engineer, from East Buffalo to Newark, 93 4 miles; and Engine 50, Martin Pearce, engineer, from Newark to Frankfort, 108 3 miles. Both these engines are of the West Shore class "B," having outside cylinders, four coupled wheels, and a leading four-wheeled truck. They were built by Rogers, of Paterson, N.Y., from the designs of the late Mr. Howard Fry. The leading dimensions are:—

Cylinders, 18in. × 24in.; drivers, 5ft. 8in. dia.; truck wheels, 2ft. 9in. dia.; crs. of cyls. apart, 6ft. 5in.; mean diam. of boiler (straight top), 4ft. 8in.; length of barrel, 10ft. 7in.; thickness of sheets (Otis steel), $\frac{7}{16}$in.; height of c.l. of boiler from rail, 7ft. 5¾in.; inside firebox, length, 5ft. 10⅜in.; inside firebox, width at bottom, 2ft. 10¼in.; mean height, 6ft. 1¼in.; number of flues, 188; diam. ext., 2in.; h.s. of flues, 1,084 sq. ft.; h.s. of firebox, 128 sq. ft.; total, 1,212 sq. ft. Smoke box (extended), 4ft. 11in. diam.; smoke box, length, 6ft. 2in. Fuel, bituminous coal; weight in w.o. on drivers, 62,500lb.; weight in w.o. on truck, 32,000lb.; total, 94,500lb. Weight of tender loaded, ⅔ max. capacity, 54,000lb. Engine fitted with Westinghouse brakes on drivers and tender truck wheels.

Referring to letter 24526, p. 455, it may perhaps put "L. N. W.'s" mind at rest to know that 444 miles without stop was actually made on the P.R.R. from Jersey City to Pittsburgh.

**Yankee Loco.**

## LIST OF TRAINS—CORRECTIONS AND ADDITIONS.

[24582.]—G.N.R.—

No. 2 should be 29¼, not 29½ miles. The rest is correct.

5. Stations omitted should be Retford and Doncaster.

6. Finsbury and Peterboro .. 73¾, 84, $52\frac{57}{84}$

8. Huntingdon and Finsbury 56¼, 63, $53\frac{4}{7}$

14. Finsbury and Peterboro .. 73¾, 86, $51\frac{39}{86}$

20. Finsbury and Peterboro .. 73¾, 87, $50\frac{75}{87}$

Additions.—

King's-cross—Grantham.. 105½, 126, $50\frac{5}{21}$
1 Man. and Sheff. ex.

Peterboro—Finsbury .... 73¾, 87, $50\frac{75}{87}$
1 Scotch ex.

Peterboro—Finsbury .... 73¾, 88, $50\frac{25}{88}$
2 (1 Scotch, 1 Man. express).

Express mileage over 50, not including trains running on Sundays or special days—

| | |
|---|---|
| Great Northern Railway.......... | 2,472 |
| London & North-Western Railway. | 883½ |
| Midland Railway ................ | 527¾ |
| Great Western Railway .......... | 499¼ |
| Manchester, Sheffield and L. Ry. .. | 360 |
| North-Eastern .................. | 44¼ |
| | 4,786¾ |

L.N.W.R.—

Willesden—Leighton, 35, 42, 50, 1 Birmingham express. No. 2 runs on Sundays only.

## NEW REMEDIES FOR CORNS.

[24583.]—Corns are not exactly a scientific subject; but probably the man who could provide us with an easy and efficient remedy would earn the thanks of the multitude, just as much as some of the inventors have done, especially if he gave his discovery freely to the world and omitted the royalty.

According to the *Chemist and Druggist*, salicylic plaster has recently been put upon the market as a cure for corns, bunions, and thickened skins generally. The price is reasonable enough, but some may prefer to make it for themselves. Dissolve two drachms each of salicylic acid and common yellow resin in six drachms of sulphuric ether, and paint the solution over belladonna or opium plaster spread on swan's-down. The mixture dries almost instantaneously, and the plaster is then ready for cutting up into suitable sizes for corns. Considering that the whole does not cost more than three or four shillings per yard, and that several thousand plasters may be made out of that quantity, it is cheap.

Some corns are so painful that neither paint nor plaster can be endured, something of the nature of a shield alone giving relief. For such cases as these, the following wrinkle may be appreciated: Take a corn-shield, enlarge the diameter of the hole to a small extent by means of a knife or scissors, and apply in the usual way. Then place in the hollow thus formed over the corn, a small quantity of any of the following solutions: Salicylic acid and extract cannabis indica dissolved in ether; or, extract cannabis indica, one-half drachm, dissolved in two drachms of liquor potassæ; or, a saturated solution of iodine, or iodide of potash, in strong alcohol. The shield does the double service of taking the pressure of the boot off the corn, and at the same time preventing the liquid being rubbed off by the sock; while all these solutions penetrate the skin much more rapidly than the usual collodion preparation, and are consequently much more effective in their operation. The saturated solution of iodine often succeeds in removing corns and indurated epidermis when other remedies have failed, and the well-known solvent action of liquor potassæ is a sufficient credential to induce for it at least a trial.

Many corns can be removed by a persevering application of the ordinary shields, which, relieving the pressure of the boot, enable nature to throw off the old skin. Acetic acid, too, is an excellent remedy for corroding the indurated epidermis; but it is necessary to protect the surrounding parts by means of a paper shield.

**Pharmakeutikos.**

## HIGH CHIMNEYS.

[24584.]—In the English Mechanic of July 31st, under the head of "Useful and Scientific Notes," the paragraph on "High Chimneys" gives the height of the huge one at Messrs. Townsend's Chemical Works, Glasgow (468ft. from the foundation), and goes on to say that it is "the loftiest building in the world excepting the Great Pyramid of Ghizeh, the spire of Strasburg Cathedral, and that of St. Stephen's, Vienna." This is a mistake, for there are at least three buildings, each of which is of greater height than any of the above-mentioned—viz., the Washington Monument, at Washington; the City Hall, Philadelphia (both of which I had the pleasure of viewing recently); and Cologne Cathedral. The height of the Washington Monument from the floor is 555ft. 4in.; the City Hall, Philadelphia, 537ft. 4in.; and Cologne Cathedral, 524ft 11in. The height of the Great Pyramid of Ghizeh has been variously stated at 460ft. and 480ft., and the same remark applies to St. Stephen's, Vienna, which has been given at 441ft. and 452ft. Strasburg Cathedral and Townsend's chimney stand equal at 468ft. From foundation to top the Washington Monument measures 592ft., or 124ft. more than Townsend's chimney. It is without doubt the highest building in the world, and to some of the readers of the English Mechanic the following may not be without interest:—

"The building of the Washington National Monument at Washington was completed on Saturday, December 6, 1884, by the setting of its marble copestone and metal finial of aluminium. The idea of this national monument took definite shape in 1833, when citizens of Washington formed an association to build it by popular subscriptions of individual sums not to exceed one dollar each. Chief Justice Marshall was the first president of the association. In 1847 the collections footed up only 87,000 dollars. With this sum it was determined to begin the work. On the 4th July, 1848, the corner stone of the monument was laid; in 1854 the funds of the National Monument Society, amounting to 230,000 dollars, were exhausted. The monument had then reached a height of 170ft., including the foundation, and during the succeeding 24 years only 4ft. were added. On August 22, 1876, Congress passed an Act creating a joint commission for the continuance and completion of the monument, and made the necessary appropriation, which was continued annually. Before resuming work on the old shaft, it was deemed best to strengthen the foundation by placing under it an additional mass of cement concrete to a depth of 12ft. 4in. This mass was extended 23ft. 3in. beyond the old foundation, or 126ft. 6in. square. The weight of the mass then worked under was 32,176 tons. The total pressure of the foundation, obelisk, and earth on top of and within the foundation as it stands is 80,378 tons, or a mean pressure of over five tons to the square foot. A slight deflection of the axis of the shaft of the old structure was corrected, and the total settlement of the completed shaft has been but 4in., of which 2½in. occurred during the underpinning. The monument is a marble obelisk. The shaft from the floor is 555ft. 4in. high, being 30ft. 5in. higher than the spire of the great cathedral at Cologne, Germany. The present foundations are 36ft. 8in. deep, making an aggregate height from the foundation bed of 592ft. The base of the obelisk is 55ft. 1½in. square, the walls 15ft. ¼in. thick, and at the 500ft. mark, where the pyramidal top begins, 34ft. 5½in. square, and 18in. thick. The amounts expended for the monument to the date of December 6th, 1884, were as follows: By the Monument Society, 230,000dols.; appropriated by Congress, 900,000dols., making a total of 1,130,000 dols. Within the obelisk (the walls being vertical) is an elevator and stairway, both of which will be fitted up for visitors after the workmen finish. From the top of the wall of the obelisk to the bottom are 900 steps, about twenty minutes being required to make the descent. On the four faces of the metal point forming the apex of the monument, the following inscriptions are engraved: 'Chief engineer and architect, Thomas Lincoln Casey, Colonel Corps of Engineers; assistants, George W. Davis, 14th United States Infantry; Bernard R. Green, civil engineer; master mechanic, P. H. McLaughlin. Corner-stone laid upon bed of foundation, July 4th, 1848. First stone at height of 153ft., laid August 7th, 1880. Cap-stone set December 6th, 1884. Joint Commission at setting of capstone: Chester A. Arthur, W. W. Corcoran (chairman), M. E. Bell, Edward Clark, John Newton; Act of August 2nd, 1876'; and upon the last one 'Laus Deo.' The monument was built from the height of 150ft. to 555ft. of marble, from the quaraies of the Beaver Dam Marble Company, Baltimore County, Md., Hugh Sisson, president, between the dates of August 21st, 1880, and November 14th, 1884."

**John Wood, D.D.S., L.D.S., Ed. & I.**

Dumfries, Aug. 3.

## CAN ALUMINIUM BE EXTRACTED CHEAPLY?

[24585.]—I see this question is again cropping up in your pages, and one contributor actually says that he easily obtains calcium. I send you particulars of a process invented in the United States by Mr. F. J. Seymour. His formula is substantially as follows: Zinc ore 100 parts, kaolin 50 parts, carbon either as anthracite coal or its equivalent in hydrocarbon gas 125 parts, pearlash or its equivalent 15 parts, chloride sodium or its equivalent 10 parts, and may be varied somewhat, all these parts (except hydrocarbon gas when used) to be intimately mixed together by grinding under heavy rollers. It has been found that the earths or ores peculiar to America carrying aluminium are mainly composed of silica and alumina in about equal proportion—viz., on average 50 per cent. alumina and 45 per cent. silica, the balance of parts being moisture and impurities. The union of the alumina and silica as found in the natural earths is a mechanical, not a chemical one, and it has also been found that all attempts to cast down the metal from the natural earths directly or by any process analogous to the general method of metallurgic operation, or to the method generally in use for the distillation of zinc ores, have failed for the reason that alumina in its natural condition as found in the various earths is so very highly sublimated, also so very light in its specific gravity when reduced into a metallic condition, that all the common methods of treating by heat either in an open crucible or by distillation will fail to cast down in any way analogous to the common methods of treating ores. The method herein described consists mainly in the use of zinc ore of the calamine or carbonate order with kaolin or earths carrying alumina, for the reason that the one metal has such chemical affinity for the other, and the one such greater specific gravity than the other, that when mixed in proper proportion and subjected to heat under conditions as hereinafter explained, the one will act as a flux, and assist in liberating the oxides to be taken down together either as the oxides of the two metals or in a metallic condition. The deposit of alumina in all the rocks and earths is found in such sublimated condition as to approach more closely than most other deposits of mineral to what may be stated as condensed or congealed atmosphere, and under a moderate degree of heat is expelled in such rarefied vapour as to escape observation.

A quantity of kaolin placed under heat in open crucible (showing 40 per cent. alumina by critical analysis) will before the silica is calcined have entirely disappeared, so that no trace is found by the same analysis as the one preceding its being placed under heat.

Many inquiries have been made attempting to determine from what source the great deposit of alumina projected. Geologists determine that one-eighth per cent. of the entire crust of the earth is an aluminous deposit. There are certain localities and special formations of the earth's surface that show in excess the deposit of this mineral, notably the drift clays in America. The process described proposes to treat kaolin in its natural condition direct by heat, and includes making use of such fluxes as may be used to advantage in its reduction and concentration and delivering it either in the condition of oxide or metal.

Distillation under heat carried up to that degree which will liberate the mineral contained in the kaolin or other ores in vapours, conducting the vapours into a condensing chamber, from thence taking the condensation automatically down and out into settlers, easy of access for subsequent treatment and reduction into metallic aluminium. The analogous chemical properties of zinc and aluminum, also the similar character of their natural depositions, including the low and uniform degree of heat at which they are fused, and from the fact that the same agents or acids will act upon both metals equally, and hold in solution, also that the same reagents will precipitate, furnish the basis of Mr. Seymour's method of treatment.

The furnace may be constructed so as to carry in number from one to several hundred retorts, each of which will receive for one charge about 100lb. of the above mixture. The retorts may be of plumbago, preferably of steel of such temper as will not fuse under 4,000 deg. F. These retorts are coated on their inner surface with a refractory material, preferably quicklime and borax in equal proportion held in solution of that degree of plasticity that the coating may be uniformly laid upon the inner surface. The retorts are, inside dimensions 36in. long, 12in. diameter, with sides, $\frac{7}{8}$in. thick. They are set vertical in a furnace chamber separated by about 4in. from contact with any other of the same series; the chamber to be heated preferably by gas to insure great uniformity of heat, which should be carried continuously at about 2,500 deg. F. The degree of heat applied and the uniformity with which it is conducted will determine the length of time needed to effect complete reduction of the ores. Properly handled, the furnace should make two charges in 24 to 30 hours. The retorts are so arranged that access may be had to the contents at the bottom for a two-fold purpose—one to reach and remove the ashes and cinders occasioned by the reduction, and also to obtain any metallic deposit resulting from the action of the heat and fluxes; the other purpose, to be enabled at any time to project hydrocarbon gas into the retorts and through the contents, thereby giving direction to the vapours liberated into the condensing chamber, making one of the essential conditions of having under control the amount of heat within the retorts, also determining to a great extent the character of and rapidity with which work may be accomplished. The retorts are also provided at their upper end with an adjustable cap or cover, fitted so as to be centrally placed thereon, also fitted centrally with an outlet pipe connecting with a main pipe leading into a condensing chamber. Each retort is also so arranged as to be operated singly or in connection with a series of retorts placed in the same furnace. They are also so arranged as to be charged with fresh material without disturbing the proper working of any other one of the same series. The condensing chamber to which the vapours are conducted should be, for a furnace of 10 retorts, about 8ft. diameter and 8ft. long, of thin copper fitted with proper connection to the pipe to which each retort has access, also provided at its outer end with an outlet pipe provided with a valve. The condenser should also be provided with an inlet pipe at its uppermost surface, projecting into the condensing cylinder for sufficient distance to allow space for a perforated cap through which is to be projected into the condensing surface water or other fluid in a finely diffused spray. The condensing cylinder is also provided with an outlet pipe at its extreme lower surface. This pipe is also provided with a valve to regulate the flow from the condensing cylinder, through the outlet pipe, into a series of settlers as fast as condensation has taken place.

Mr. Seymour says: "I have found it advantageous to use zinc ore in excess over that of aluminium ore, and for the reason that actually the zinc begins vaporisation first, and at about 200deg. F. below the point at which the alumina commences vaporisation from the kaolin, and hence the advantage of having and using appliances by which complete control may be had over the contents of the retorts, and by observation and regulation, or adjustment, of the valve on the outlet-pipe of the condenser, one can determine at all times the character of the condensed oxides."

I have said enough, however, to give an idea of this improved process; but it appears to me that, like most other discoveries, it wants a deal of proving, while so far as I can see it results only in the production of alumina. **Metallurg.**

### A POCKET FIELD MICROSCOPE.

[24586.]—A POCKET field microscope, magnifying 100 diameters, useful in the search for infusoria, &c., and which may be constructed, lens and all, in a few minutes.

Bend a slip of thin metal 5in. or 6in. long and $\frac{3}{8}$in. wide into the form of the letter V, make two circular holes $\frac{1}{10}$in. in diameter, one in each arm, opposite each other, so that when the arms are sprung together by pressure the holes shall meet exactly. Place a drop of water in one hole, taking care not to wet more than its interior circumference. The water will assume the form of a perfect double convex lens, of focal length varying from $\frac{1}{8}$ to $\frac{1}{10}$ of an inch according to the quantity of water introduced. Such lens, though by evaporation its focal length is gradually increased, maintains its efficiency for a time quite sufficient for the examination of a drop of water, or other substance in the opposite hole. The end of one arm of the V is bent inward so as to form a "stop," which when they are pressed towards each other to effect the focal adjustment, prevents a contact which would destroy the lenticular form. The flame of a candle gives the best illumination of the field. In the open air the diffused light of the sky gives an unsatisfactory illumination; but if it is modified by passing through the nearly-closed hand, placed in front as a diaphragm, a favourable definition is obtained. The definition of these water-lenses is excellent, and their magnifying power is from 80 to 100 diameters according to the quantity of water in the lenticular drop. I inclose specimen.

Stoneaston, Aug. 2. **J. Hippisley.**

### RIFLE SHOOTING.

[24587.]—IT is hardly possible that amongst the large number of readers of the "E. M." there are none who are interested in the use and practice of the rifle. Having myself been for many years associated with the burning of powder, I still have a liking for it that induces me to investigate any matters connected with it; and for the benefit of those who take a delight in being an efficient marksman, I now write this. That every volunteer rifleman, for instance, to possess a rifle range of his own on his private premises would be impossible; but practice with the regulation weapon is now made safe, easy, and cheap, by several appliances introduced of late. I am not aware who the individual was who devised the plan of utilising the service rifle; but he deserves well of his country at any rate. The practical outcome of this is an apparatus, in one instance, fitting into the breech of the service rifle so that a diminutive cartridge instead of the full size one is used, No. 1 bulleted caps being the ammunition. A target, of suitable size, of paper being affixed to a piece of stout wood, we may fire away in one's own garden, or in a room of sufficient length. Such practice has a most beneficial result on the shooting of recruits, whilst good shots can keep up and improve their shooting. The most recent form coming under my notice is that of a tube fitting for its whole length into the barrel, the cartridge being minute, as I mentioned before. The practice obtainable at a range of 100 yards from the target giving the marksman the practice of firing at the regulation target at distances of from 200 to 800 yards. Where space is more scarce, another form of instructor I have can be utilised with a range of 10 to 50ft., giving all the equivalents of longer ranges.

I should consider that amongst your readers there must be many who would desire to get home practice with the regulation weapon; and a choice of the two instructors I have would give every facility so long as the range of from 5 to 100 yards be available. These small cartridges produce but little noise—not sufficient to be an objection. Should my remarks attract the notice of anyone else interested in the matter, I shall be very pleased to have something further to say on the practical use and experience of such aids to good shooting.

**Invicta.**

### WHAT IS "CREATION"?

[24588.]—To make a new thing that also has a connection with the universe. To make a thing that has a beginning and an end, which the universe has not—viz., derived from the universe, yet is self-existent in itself. Creation has only relation to the individual, because the individual is distinct from all others, yet bears a likeness to all things. To explain. Take a leaf from any plant or tree, compare it with the other leaves on the same parent stem, or any other same or different species, and a variety in likeness is certain; compare the two halves of the same leaf, they are different in their likeness; quarter it, cut it into a thousand pieces, they are all alike yet different. 'Tis the same leaf that is different to itself, and to all other leaves. A leaf is a world in itself, so is a grain of sand.

No human hand, foot, or other member is exactly like mine, yet I am related to all men, animals, and plants, for we are all alike yet diverse; hence comes the variation of men, animals, and plants (without domestication, begging Darwin's pardon). There is no need to observe the various yet connected forms in a natural history museum, only remark the variation in one's own body. Everything is created in pairs, which are alike yet different, and is caused by an original or primal centre, which physiology attributes to the brain in the propagation and continuance of its kind from beginning to the end of its creation, in the individual. All are agreed that each individual (creation) is from a centre, which without fail divides in two, which two divides over and over again into almost infinite ultimates or functions, and always in pairs, as cells, glands, nerves, muscles, flesh, and bones. It seems a contradictory business, for the bones are interior yet recent, while the nerves and flesh are external yet first in the advent. We shall find this rule paramount in all; a sort of agreement to differ.

What! You shall ask five hundred children a question, and they will all answer differently. Do you say that creation is a finished fact? Of what use, then, is this wealth of imagination often conveyed in erroneous answers, and is everything cut and dried? Per contra, "there are sermons in stones and good in everything." Then we have monstrosities in nature, albinos', anthropoid apes, poisonous and vicious animals, &c., all wrong answers to man's call for higher intelligence and the human form divine; yet these all form a part of man, he alone contains them all, a contradiction in himself, and yet like all the others. A fox is always a fox, but a man can be fox, sloth, and lion in one. Pope says that Homer had the greatest invention of all poets; but what shall we say to that greatest of all inventions, the vertebrate form, agreeing yet differing in all its species, from 300ft. long down to a microscopic arrangement.

Seeing, then, that the universal law is opposition in unity, or likeness in unlikeness, we perceive that creation is an individual fact, same as heat and cold are only different degrees of the same temperature.

**Fiddler.**

### MYSTIFICATION.

[24589.]—PRAY, sir, what is a person to understand from M. de Fromelin's hypothesis (page 473) of the floating of the particles of which clouds and dust are composed? "That a special atmosphere surrounds each particle—that the attraction which retains it is within the domain of molecular forces"! Query, is "it" the atmosphere or the particle? And then as to the floating in the "vesicle or particle surrounded by its atmosphere (special, of course), the thermal absorption of the water is much greater than that of the surrounding diathermanous air; the atmosphere (special, again) of the vesicle is consequently expanded, and so it floats in the circumambient air"! This, surely, is science mystified with a vengeance!

Any person who has carefully studied clouds, fogs, or even the waste steam blown off from a locomotive, knows that these particles are continually sinking in the atmosphere, but that this sinking is lessened in velocity by their friction through the air, their surface being so enormously increased by subdivision in proportion to the relative weights of equal bulks of water and air—e.g., a cube foot has 864 sup. inches: divide it into cube inches, and the surface is increased to 10,368, and so ad infinitum. This, I fancy, is the simple explanation devoid of mystery.

The above leads me to the remark that those who have the pleasure of attending our different scientific meetings have sometimes this pleasure considerably interfered with by mystification in one form or other, notably so by the inordinate use of abstruse formulæ on the "Black Board," which not one in a thousand can either follow or care to understand, when the result, in plain terms, would be both interesting and instructive. Again, in writing the use of chemical algebra and nomenclature is well enough for chemists, but there are people well instructed in other branches who would much prefer "sulphate of copper," or even, if the learned person preferred it, "cuprous sulphate," to "$CuSO_4$. Uncharitably profane people say that mystification is a modus operandi in the "capital market," but this must not be believed.

**Rho.**

**Green Peas and French Beans** are preserved for winter use in France by the following course of treatment: They must be mature and fresh and dry to begin with. If old they are not worth keeping; if very young they will not keep well, being too watery. Take a middle-sized stewpan and nearly fill it with peas or beans, over which sprinkle, very lightly, pounded loaf-sugar. To a quart of peas there should be added two tablespoonfuls of sugar. Put the pan over a slow fire, and carefully stir two or three times. As they become heated a little water will flow from them, which is the sign that they are heated enough. Turn them out on a soft cloth to drain, and when rendered as dry as possible remove them to sheets of paper spread out in an airy room. In doing this look for any that are bruised or discoloured, and remove them. When quite dry pack them in smallish earthen jars, and tie down and store in a cool dry place. If they are not quite dry mildew will soon appear and render them worthless. But if the work is well done they will be coated with a thin glaze of sugar, which is peculiarly preservative in its nature. French beans preserved in this way are of a good colour and flavour when used in the winter, and will require only the ordinary process of cooking. Green peas fully grown, but still tender, may be preserved for soups by spreading them on trays or papers and drying them in a cool oven—say, not hotter than the hand can bear without inconvenience. They will be much shrivelled, but will be excellent for soups and ragouts.—*Amateur Gardening.*

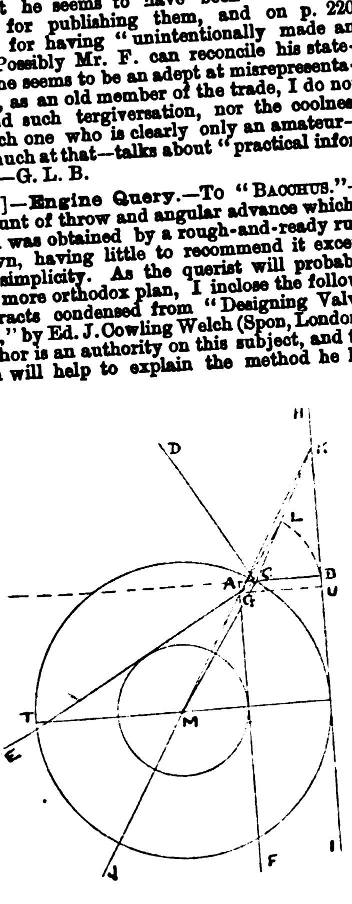
**Razor Paste.**—Mix fine emery intimately with fat and wax until the proper consistency is obtained in the paste, and then rub it well into the leather strop. Prepare the emery by pounding thoroughly in a mortar the coarse kind, throwing it into a large jug of water, and stirring well. Immediately the large particles have sunk, pour off into a shallow plate or basin, and let the water evaporate. Another recipe is, levigated oxide of tin, prepared putty powder, 1oz., powdered oxalic acid $\frac{1}{4}$oz., powdered gum 20gr.; make into a stiff paste with water, and evenly and thinly spread it over the strop. With very little friction this paste gives a fine edge to the razor, and its efficiency is still further increased by moistening it.

# REPLIES TO QUERIES.

**** In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[56676.]—**Free Reeds.**—It is not impossible that I fail to comprehend the "exact requirements" of this querist, as Mr. Fryer (p. 481) says; but as Mr. F. thinks it necessary to "remind" me that the querist requires to know how to tune reeds, I can only point to the query which appears on p. 268, and remind Mr. F. that it says nothing about the actual methods of tuning reeds, but asks how to "make a tuning apparatus." I have already recommended the querist to use the exhaust principle, and told him that three holes will be sufficient for all practical purposes; the question obviously has no reference to the tuning of reeds in an instrument, because that is known as fine-tuning and is always spoken of—even by novices—as "tuning the instrument." I have always understood that queries were inserted for the benefit of all, and as I knew nothing of Mr. Fryer's private correspondence, it seemed to me that his reply to this query was wide of the mark, for it did not give the slightest idea of the "tuning apparatus" asked for by the querist. Now as to the price of reeds, it is not a question of what local dealers charge. On p. 199 Mr. Fryer said that a set (5 octaves) costs 6s. 6d., but on p. 220 he said he had made a mistake, and that the price of a set should be 10s. 6d., but in spite of his own statements he retained an "unalterable opinion" that 18s. is a "very moderate charge for a set of reeds of good quality." There are no better harmonium reeds made than those sold by Esteve, of Paris; he has two agents in London, and the average price asked is 10s. 6d. I say "average" because the price varies according to the "style" of the reed. Thus, the price of the small set for Bassoon is 9s. 6d.; the broad bent 11s. 6d. Why Mr. Fryer, in view of this simple fact, which is well known to, or can be readily ascertained by, anyone interested, should retain an "unalterable opinion," and imply that 18s., 20s., and even 25s. are fair prices, is best known to himself; but I think what he has written on this matter from first to last is a splendid example of that "theoretical humbug and misconception" (p. 437) which he appears to deprecate. The prices he gave for fittings on p. 199 are the wholesale prices for the cheaper kinds; but he seems to have been "called to account" for publishing them, and on p. 220 apologises for having "unintentionally made an error." Possibly Mr. F. can reconcile his statements, as he seems to be an adept at misrepresentation; but, as an old member of the trade, I do not understand such tergiversation, nor the coolness with which one who is clearly only an amateur—and not much at that—talks about "practical information."—G. L. B.

[56798.]—**Engine Query.**—To "BACCHUS."—The amount of throw and angular advance which I gave you was obtained by a rough-and-ready rule of my own, having little to recommend it except extreme simplicity. As the querist will probably prefer a more orthodox plan, I inclose the following extracts condensed from "Designing Valve-Gearing," by Ed. J. Cowling Welch (Spon, London). The author is an authority on this subject, and the diagram will help to explain the method he has adopted.



**Greatest port opening, lead and cut off point being given, to find lap, throw, and angular advance.** Draw A B = maximum port opening, and let A C = lead, and B C D the angle travelled by the crank before cut off. Draw C E ⊥ C D, and A F ⊥ A B intersecting at G. Through B draw H I parallel to A F. Bisect E G F at J and produce J G to K. Join K C, mark off G L = G U = A B. Join L G, and from C draw C M parallel to L G, intersecting J G at M. Draw T M parallel to A B, then C M T is the angular advance, and M C is the half-travel of valve. The radius of the small circle gives the amount of lap.—BACCHUS.

[56804.]—**Fifteen-Lighter Dynamo.**—See answer to "Electra" query 57050.—W. H. EAVES, Coventry.

[56809.]—**Dynamo for Arc Lights.**—To W. H. EAVES.—I am sorry I cannot comply with your request for details of 12in. armature and magnets, because to have every proportion right each detail has to be separately worked out. It would take a day and a half of hard work to do your query justice, so I think you had better employ a professional electrician, whose fee for drawings and specification would not come to much. The 8in. armature, if wound for arc lighting, would give two lights of over 2,000 c.p. each. If this would suit you, I shall be happy to give you all information.—W. H. EAVES, Coventry.

[56888.]—**Bicycle Turning.**—I am not sure that I understand "J. R. T.'s" difficulty; but I think he will find it removed if he reflects that the wheels at any instant touch the ground only in points, and that the small wheel must follow the large one, or be wrecked.—ESSAR.

[56889.]—**Protosulphide of Iron.**—"C. D." may prepare ferrous sulphide by bringing white-hot iron into contact with sulphur, or by throwing borings of iron and sulphur in powder into a red-hot earthen crucible. The proportions are seven parts iron, four parts sulphur.—F. R. J.

[56890.]—**Filtering.**—If "C. D." wants to filter by the aid of a vacuum, he had better try the pump, unless he has steam to spare, and uses an ejector.—H. R. T.

[56892.]—**Tricycle Chain.**—It wants tightening up a bit, that is all; but you will have to get a smith to do it.—ESSAR.

[56894.]—**Oils.**—Filter through canvas, then felt, and after that animal charcoal. If not clean enough, you must treat them with acid by the methods often given for bleaching oils.—ESSAR.

[56896.]—**Loco. Slide Valves.**—See p. 343, Vol. XXXVIII., and for indicator diagrams, pp. 130, 244, 272, Vol. XXXVII. You will find all you want to know in back volumes, but the pages given have diagrams which will help you.—T. J. M.

[56898.]—**Naphtha.**—It is a hydrocarbon gas, but what, it is impossible to say, especially as "F. S. Sc." does not state whether it is wood or mineral naphtha he means.—A. S. Sc.

[56901.]—**Irish Degrees.**—There is Dublin University, the Royal University of Ireland, and the Catholic University of Ireland; but as to the arrangements "Student" should inquire direct of the registrar in the first case, and of the secretary in the others.—CLONMEL.

[56908.]—**Caloric Engine.**—"Invicta," on p. 395, says "asbestos is not, as a rule, a good packing at all for glands or parts in motion. But I can show 'Romeo' how to get over that." Would it be too much to ask "Invicta" to kindly explain "how to get over that" in these columns? The information might be useful to many readers besides "Romeo." Perhaps Mr. J. Boyd (p. 368) would give some information on this point, and possibly show "how to do it" at the stand in the Exhibition. There is little enough there now; but as the noisy machine is making packing, no doubt Mr. Boyd can tell us how to utilise it to the best advantage.—H. MAUDSLAY.

[56912.]—**Jablochkoff Battery.**—"J. H. G." had better leave this battery alone until it has been successfully tried in a practical manner. Newspaper reports of effects produced by electrical appliances are not always accurate.—NUN. DOR.

[56920.]—**Locomotive.**—Surely "S. S." must see that how often a loco. boiler requires washing out must depend on the character of the feed-water: it might be once a week, or once a month, or even once a twelvemonth when pure water is used; but where will that be found along the whole length of a line? New tubes will be wanted, say, once in five years; but really "years" have nothing to do with it—the life of a loco. is reckoned by miles run; so say new tubes after 120,000 miles.—NUN. DOR.

[56923.]—**Bleaching Shellac.**—Permit me to suggest to "J. L." that he would learn much more by just trying a few experiments himself than by reading any number of columns of replies. The "cement" is, no doubt, any ordinary luting; Glycerol is glycerine. But if the querist wants to bleach shellac, he will find several recipes in back volumes, and if he will say for what purposes he uses it, I will direct him to a recipe, or give a process. Perhaps the easiest is to dissolve the lac in spirit, mix it with animal charcoal, and expose to the light for some days in closed bottles; but if the lac is required in the solid form, perhaps the acid process is best.—NUN. DOR.

[56926.]—**Leaky Tank.**—Empty tank, let it dry, and coat it with solid paraffin, using hot flat-irons to drive the wax in.—C. M.

[56929.]—**Cork-Cutting Machine.**—One illustrated on p. 181, Vol. XXXVIII.—T. G.

[56950.]—**Lead Burning.**—There is something wanting still to make this matter clear, the present net result of the "Replies" received amounting really to a gratuitous advertisement of Messrs. Briggs and Co.'s patent machines; without, however, the slightest scrap of information as to what such machines really are, how they are worked, or what liquid is used in them. Surely, Sir, this is contrary to your rules, and as some recompense, I ask that they shall give us a full specification and description of them and their use; and also the number of their specification. I may add that on a recent visit to the "village" I went two days in succession to the "Inventions" to see this machine; but no one was in attendance to explain its merits. The attendant at the next stall could not say when anyone would be there, and the machine, although marked "patent," did not bear the patent number; and the "leaflets" left on the stall "pro bono publico," while fully describing the benefits (which any practical man will at once concede) of avoiding the use of the "fire-pot," gives no information at all; in fact, like Messrs. Briggs's first letter in "Ours," they carefully *conceal* all that is desirable to know before anyone is inclined to purchase. It is quite possible that I might have been a purchaser had all information been forthcoming in an open, straightforward manner.—FINEM RESPICE.

[56956.]—**Ball Bearings.**—If Chas. Hosken will take one of his gunmetal bearings and a ball bearing and fill both with road dust, he will soon find a difference, I think. Give each a certain number of turns, after which it will be found that the balls have suffered little, if at all; while the gunmetal will be torn and scratched to pieces. A spindle borne on balls certainly runs lighter than one on an ordinary bearing—why, I don't know; I only go in for facts, and have *no* belief in theory.—F. SHAKESPEAR, Dresden.

[56956.]—**Ball Bearings.**—In a bicycle a wide bearing is impossible on the driving-wheel; about 1in. or $1\frac{1}{4}$in. is as much as can be had. In a steam-engine the bearing can be made any length; but it is not exposed to the grit of dusty roads. A locomotive does not run through such dust as a bicycle, and while the locomotive is constantly being cleaned, the bicycle not often gets a wipe. The box of the ball bearing may become full of so much macadam, but less power is required to grind up substances by means of balls than is required to grind by means of two surfaces rubbing together. As the balls grind by rolling round, and being of hardened steel, the grit does not become imbedded in them. With gunmetal it is otherwise; being soft, it is soon imbedded with grit, which wears away the steel axle. This latter becomes scratched and grooved, and these get filled with smaller grit, and in their turn grind away the gunmetal. To say that several first-rate riders are thoroughly opposed to ball-bearings is no better than saying one has driven a tricycle 5,000 miles and it carries less weight.—F. SHAKESPEARE, Dresden.

[56961.]—**Boating.**—To "INVICTA."—I am glad you have made the whole theory clear to yourself, and hope "Aqua" has also. I shall, as soon as I get time, make the machine, and if more power should be required I can easily add it; but I should not think there would be much power required for a small boat that will not carry more than two persons, as "Aqua" speaks of in No. 1059. Mr. J. Adams speaks of one he has seen that will go eight miles an hour with half the labour of rowing. If Mr. J. Adams could favour us with the sketch it would no doubt benefit our readers. I daresay particulars and sketch of "Invicta's" plan would be favourably received.—T. HANDEL.

[56969.]—**Hydraulic Ram.**—I am sorry "Invicta" should think that I have misquoted him. If he will look back he will see that I have faithfully given his very words; they are, p. 439, "No doubt the valve is made in itself heavy enough to more than balance the permanent head of water," and just before he had said, "the pressure of the head of water itself would not support the escape valve." It is the truth of these statements taken in their plain and obvious sense that I dispute. With regard to "Invicta's" remarks, p. 481, about a light valve not waiting for the water to attain its proper velocity, I would say that there is practically no fear of a valve being made so light as this, seeing that it must have substance enough to stand the repeated shocks of impact. When extra weight is given or added, it is usually with the idea of assisting the fall of the valve, which it does to a small extent, though at the expense of efficiency. The whole weight of the heavy valve, however, would not equal one-twentieth part of the permanent pressure.—W. A. S.

[56977.]—**Strength of Beams.**—The relative strength of beams of rectangular section among themselves, and of circular section among themselves, is represented by the formula $\frac{BD^2}{L}$; but it does not apply to the comparison of rectangular with circular sections. Beams of square section vary in strength as the cubes of the depths, and beams of circular section as the cubes of the diameters. Taking the strength of a square section as unity, the strength of a circular section of the same depth is $\cdot 7854 \times \frac{3}{4} = \cdot 589$. When the areas are equal the strengths are as 1 to ·75. I hope "Dubliniensis" will show how his results are arrived at.—J. S. C.

[56988.]—**Siphon.**—It is usually supposed that to insure the action of a siphon, one leg must be longer than the other; but it is not so. It may be convenient to lengthen the outer leg to conduct the liquid into another vessel, but it is not requisite otherwise. The legs may be of equal length, yet a flow would take place. It is caused by the pressure of the column of liquid above the end of the inner leg of the siphon. As the height of the column decreases, so does the rate of the current. Any increased velocity through or below a lengthened leg must be ascribed to the well-known law relating to falling bodies.—W. B. P.

[56997.]—**Hydropathy.**—A valuable medical paper just issued says:—"The sufferer from *ennui*, which is a condition of nervousness and debility combined, must get his blood purified; he must eat but little, especially if weak. The mistake weakly people constantly make is forcing into their systems food which cannot be digested, and continues to poison the blood; or they drench themselves with tonics, in doing which they are but breeding heat and fever; or they take stimulants. This last is almost a fatal mistake, for the brain of one suffering from *ennui* is far too weak to bear stimulation. By-and-by, when the sufferer feels lighter, happier, and more hopeful, then tonics may be begun most cautiously—mild vegetable tonics first, with cod-liver oil." The momentary stimulus given by alcohol is at the cost of after-depression and wakefulness; sleep being the greatest nerve strengthener, as I find. "Quixote" for this should be as much as possible in the open air, avoiding exhausting exercise. This, with tea and coffee left off, and milk or cocoatina substituted, must greatly benefit. Rubbing with a rough towel after ablutions is very good.—C. M. Y.

[57005.]—**New Steam Motor.**—To "Invicta."—Can you give me the following information—viz., the weight, cost, and space occupied by the motor; also the power, and name of maker?—F. Shakespear, Lüttichaustrasse 14, Dresden.

[57026.]—**Problem.**—If $x$ and $y$ be the numbers of gallons of whisky,

$$16x \times 19y = 512$$
$$\text{whence } x = 43 - 19v$$
$$y = 16v - 4$$
$$\therefore v \ngtr \tfrac{43}{19} \text{ or } 2\tfrac{5}{19} \text{ and } \nless \tfrac{1}{4}.$$

"Bogie" probably intended that only integral numbers of gallons should be used; if so, $v$ has two possible values, 2 and 1.

$$\therefore \left.\begin{aligned} x &= 24 \text{ or } 5 \\ y &= 12 \text{ or } 28 \\ \text{Water} &= 15 \text{ or } 18 \end{aligned}\right\}$$

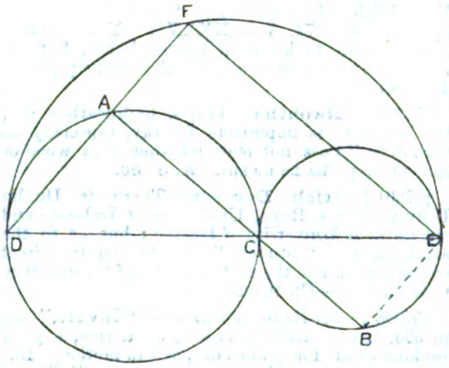
If $x$ and $y$ are equal, $v = \frac{47}{35}$, giving the result obtained by W. Hardie.—X, Y. Z.

[57028.]—**Stamping in Relief.**—I don't know that I am able to give much more information on this subject. I think I should advise him to buy the counterpart: it is most likely made of copper. He will get the brass sheet at a metal-shop; it is sold in sheets 2ft. by 4ft., that is, eight square feet, that is the regular trade size both for brass and copper, and if he wants to know where to get it he will have to advertise his address. By all means get a press, and see that it is in good order; the counter-die is fixed to the bed of the press, and the die to the plunger; whether the tickets will be cut out and stamped at one operation depends upon whether the dies are made to do that work: if not, the metal must be ruled off and cut with shears. The cost of the press I don't know; but a sixpenny advertisement will probably bring replies. The counter-die is stamped in much the same way as the tickets; but I expect it requires a much heavier press, such as would be used for coining and that class of work. Soft brass should be obtained, and the vendors should be told what it is required for. The thinner the brass is the more it will cost per pound; but per sheet it will be less. Thin metal is, of course, conducive to longevity in the dies. The metal must be clean and bright before being stamped; the lacquer is applied with a camel hair or other soft brush, the tickets having been previously heated just hot enough to hold. I don't think the dies would be suitable for stamping stationery, as I should imagine the relief would be rather too high. I don't wish the querist to be under the impression that I am practically acquainted with this work; but in the absence of other information, the foregoing may be of service.—Os.

[57042.]—**Spark Coil.**—"Spark" might try the following experiments with this coil. Pass the spark through the flame of a wax taper, holding the flame (1) under the spark, (2) near the spark, and (3) so that the spark passes over the top of the wick, and observe the modification of the spark under each condition. Attach a metal ball to one pole, and as the spark passes it is divided into a number of branches. Substitute a hollow plate of metal, and a similar division takes place, accompanied by a report. Pass the spark on to a moistened piece of guttapercha, and it will be greatly increased in length in a zigzag shape. Obtain the ordinary spark by approximating the poles, and while it passes blow upon it through a glass or paper tube (a metal one on no account), and the air passing through the spark appears ignited. Bring the poles to opposite edges of a drop of water on a plate of glass, and the spark is increased in length, passing round the edge of the water. Place one pole in a glass of water, bringing the other pole towards the surface of the water; vivid sparks pass from the water. Dip the ends of the wires in oil, the colour of the spark is green. Put a drop of oil upon tin-foil, to which one pole is attached, and bring the other to the edge of the oil. The oil appears to be boiling. Bring the other pole to the opposite side of the oil, and the boiling is intensified, and flashes of light are observed. A small quantity of gun-cotton may be ignited if held with forceps in the stream of sparks, the ignition being accompanied by a feeble explosion. All these effects would be intensified if a larger coil were employed, and stronger battery power might be necessary.—Bobadil.

[57052.]—**Weight and Stress of Beam.**—The question itself is puzzling, and the answer (page 483) is so too. Will the writers explain them?—J. S. C.

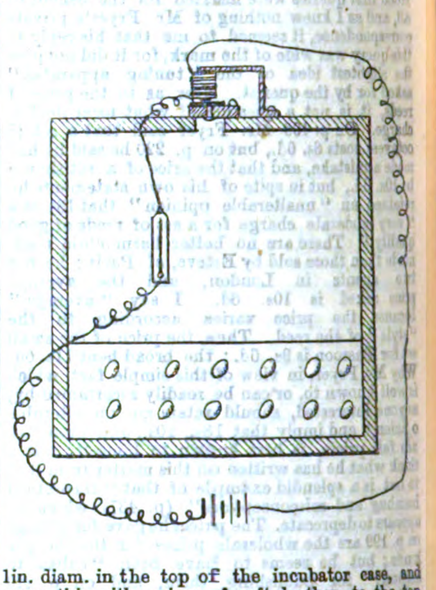
[57058.]—**Science Examination.**—C. Planck's solution of the above is scarcely suitable, as it requires a knowledge of Book VI. of "Euclid's Elements," which is beyond the requirements of Stage 2. The following is a simple solution:—



Draw D E C the common diameter of the two circles. On D E describe a semicircle, in which place E F equal to the given line. Join D F, cutting the circle on C D as diameter in A. Join A C, and produce to meet the other circle in B. A C B shall be the line required. For it is evident that E F A B is a rectangle. (III. 31). Therefore, A C, being equal to E F, is equal to the given line.—T. Watt.

[57055.]—**Electric Bells in Series.**—I think it would have been much better if Messrs. P. Jolin and Co. had given the querist the information asked for. The Editor of the "E. M." has, I think, a strong objection to replies being sent by post privately. Certain I am of this: however long the explanation referred to might have been, it would have been found room for if worth reading at all. I thought (with the querist) that the secondary coil, as it is termed, was wound in a reverse direction to the main coils, so probably it was the current passing in the opposite direction when the armature made contact, that the correspondent calls "a counter current." I think I have heard the advantage claimed for this "Jolin" bell in its non-sparking properties through the circuit never being broken. This is not any advantage over the short-circuit system spoken of. The circuit is never broken in that case, yet all depends upon a clean contact for the other bells working properly in circuit. If the two wires are wound on at once in the same direction, I agree with your correspondent, they are in the way; in fact, as he says, only introduce complications in the way of extra resistances; and if wound in a reverse direction to the main coils, it must mean an extra process, because it is quite impossible (even with the improved machinery Jolin and Co. have) to get the iron core to revolve away from you and towards you at the same time. Are we to understand the current passes through the cores when the armature makes contact in a reverse direction, thus demagnetises the cores? If so, the cores would really need to be of very soft iron to get a good result. Instead of giving evasive replies, if the inventor will give the details of construction and the advantages over other bells, he will probably find the criticisms rather an advantage to him than otherwise, the readers of the "E. M." being very keen, and they will soon suggest an improvement if this is necessary. For those interested, I would say that an engraving of the "Jolin" bell is to be found (without at all a clear description) in the *Electrical Review* for May 30th; but before answering the query, I would ask them to refer to the *Electrician*, Vol. XI. 1883, pp. 113 to 189, and the "E. M." for 1875, Vol. XXI., p. 646, and if they can see any improvement on the bells there described, to please point it out.—An A.S.T.E.

[57078.]—**Incubator.**—Obtain an ordinary electrical thermometer and connect it up with, say, three moderate-sized Daniell cells. Bore a hole



1in. diam. in the top of the incubator case, and cover this with a piece of soft leather, to the top side of which is fastened a light strip of soft iron. Directly over the strip of soft iron is suspended an electro-magnet, the coils of which are included in the circuit. Set the thermometer to required temperature; when this is exceeded the electro-magnet will open the valve, but will allow it to close when the temperature falls.—F. M. Rogers.

[57080.]—**Siphon.**—The cause of the stoppage mentioned by "Surveyor," is doubtless an accumulation of air in the highest part of the pipe.—W. B. P.

[57080.]—**Siphon.**—I cannot think that a small quantity of air—enough, say, to fill a foot or two of pipe, would stop the siphon, for, suppose the ball-cock open, what happens? The water in the long leg must descend, for it is not balanced; also the well-water must rise in the short leg, or there will be a partial vacuum. So the siphon begins to act, and the air which, when at rest, occupied the top of the bend, is carried into the long leg and hangs about in the pipe, sometimes rising and again being swept down, until the ball-clock closes, when it returns to the summit. In time, however, air accumulates in such quantity that its presence in the long leg makes that leg no heavier than the short one; then the siphon ceases to act.—W. A. S.

[57081.]—**Watchmaker's Bow.**—For strong work, use a cane bow and either thread or gut. For small work, whalebone and horsehair. The bows should be tapered towards the top to give them a good shape.—C. A. N.

[57086.]—**Colliery Warnings.**—For obvious reasons I must respectfully decline to give "Ralph" the information he requires.—T. J. Murday, Felton, R.S.O., Northumberland.

[57098.]—**Watchwork.**—To "C. A. N."—Mix diamantine the same as red stuff, using as little oil as possible, and taking care to have the stake and oil quite clean.—C. A. N.

[57100.]—**Spectroscope.**—In reply to "E. B. F.," I may tell him that I have succeeded in seeing the forms of solar prominences by the aid of a 5-prism direct-vision spectroscope by Browning, on 3¼in. Wray telescope, a short account of which he will find in the "E. M." for March, 1885. "E. B. F." should get a small box of metal chlorides (from Browning, or any good chemist), many of which are available for use with a common spirit lamp. All he has to do is to fit a bit of platinum wire about 3in. long, moisten the end, and stick a little of the chloride on it and put in the flame, and he will get lots of beautiful spectra; the other end of the wire should be held in any simple kind of clip stand. Get a drop of blood and colour a little water in a test-tube with it, and he will have two absorption bands. If he wants a simple way of seeing the sodium line reversed, get a little saltpetre and salt well mixed, roll up in a bit of paper and put on to the red embers of a fire: he will soon see a yellow band and the sodium line black in the centre of it.—T. R. Clapham.

[57107.]—**Developing Formulæ.**—A correct exposure for any one developer is correct for all others. An ounce of water must be "measured." Nawt.

[57112.]—**Wet-Plate Photography.**—The best book for all processes is "Instruction in Photography," by Capt. Abney, R.E., price about 3s. 6d. A very good shilling book is by Hughes, sold by Werge, Berners-street, W. Dry plate is easiest, but most expensive.—Nawt.

[57113.]—**Photography.**—Fry's plates are as good as any. Probably your chemicals have gone wrong, which cause the defect, or they may be too strong during this hot weather.—Nawt.

[57124.]—**Lifting Bar.**—The work done in lifting the bar is the same in both cases; but in lifting it by one end, the muscles of the hand and forearm have also to counteract the weight, acting with a leverage equal to the distance from the centre of the bar to centre of the hand.—J. S. C.

[57124.]—**Lifting Bar.**—The reason why you require more force to lift the bar at the end than in the middle, is because you raise not only the weight of the bar but also its moment, or tendency of the bar to twist round its middle point. Thus, suppose the bar was 6ft. long and 4lb. weight, the power you would have to exert at one end would be three times as much as its weight, and if you meant to raise it 4ft., this would have to be added to the work done. This being the case, you can't expect to gain time, space, or leverage.—Nester.

[57125.]—**Photo. Scrap Book.**—Since "F. A. R." objects to an album, I should certainly think cards would suit him best: they are very convenient for writing descriptions and particulars of the photos. on the backs. I cannot even suggest what size cards to use till I know what size the photos. are; and then it would be a matter of taste. The only thing is not to have them very thin. For mounting, starch or dextrine will be best.—A.R.F.

[57126.]—**Obach's Galvanometer.**—This is an ordinary tangent galvanometer, but the coil is movable, and can be inclined from its usual upright position. Thus, instead of the current being proportional to the tangent of the angle of deflection, it is proportional to the tangent of the angle of deflection of the needle, multiplied by the secant of the angle of inclination of the coil. If, by moving the coil for the different current strengths the deflection of the needle is kept constant, the instrument will then act as a secant galvanometer, and the current will be proportional to the secant of the angle of the inclination of the coil. To obtain absolute measures these values must be multiplied by the constant of the instrument.—Eugene Brown.

[57128.]—**Storage Battery.**—The best form of storage battery is as follows:—Lead plates 4in. by 6in. are bored with very small holes about $\frac{1}{8}$in. in diameter all over, and a flap of lead is left projecting at one end for connections. The holes are filled with a paste of red lead mixed with water, and they are dipped in dilute sulphuric acid (1 to 10) two or three times, and allowed to dry. When dry they are placed in jars containing dilute sulphuric mixed as before. They are then "formed" by passing a current from a dynamo through them, discharging through some resistance, and then charged the reverse way. This is done for several days, sometimes a week. After formation they are always charged the same way. If "Werdna" will give E.M.F. of his lamp, and the current it takes, I will tell him how many plates he will want.—Bunsen.

[57129.]—**Steam-Engine for Farm Work.**—In the absence of more precise information relative to the work absorbed by gearing, shafting, &c., I should recommend you to use a steam-engine with a cylinder 6in. bore and 12in. stroke, the engine to run at 160 a minute. You mention a boiler pressure of 35lb.; but the steam pressure should be at least 50lb. to 60lb., the boiler being, of course, correctly designed to be safe at such a working pressure and having a liberal margin of safety. The boiler should be 6ft. 6in. high, and 2ft. 9in. diam.; height of firebox, 4ft.; diam. of same, 2ft.; diam. of uptake, 8in.; thickness of shell plate, $\frac{5}{16}$in.; firebox, $\frac{3}{8}$in.; uptake,, $\frac{3}{8}$in. also: the firebox to have either two crosswater tubes, each tube being 8in. diam. of $\frac{3}{8}$in. plate, or, far better still, three 6in. siphon water tubes. Such a boiler may be tested to 120lb. water pressure, so that the margin of safety is very large; the total weight comes out at about 18cwt. only. Your next portion of this question comes to a different and more difficult matter for me to deal with. If coals be dear, then the gas-engine working at a cost of about one penny per horse per hour would be best, whilst the steam-engine would be independent of gas supply. If coal can be got very cheaply, then the steam-engine would run as cheap nearly as gas, but would not be always ready to start as a gas-engine is. There is also a third choice, that of the new motor advertised in the pages of this journal—the vacuum engine. After myself using one for some time to drive my electric-light dynamo and other small matters, I prefer it to both the ordinary steam or gas-engines. My reasons being that it is perfectly safe, and requires no attention for two or three hours at a time at least. If you think of making your own motor I could, I think, help you very considerably.—Invicta.

[57131.]—**Electro-Motor.**—Reversing the current through a shunt or a series motor would not reverse the direction of rotation. A shunt motor will run with its brushes, and a series motor against its brushes, no matter in which direction the current flows. In order to reverse the motor the lead of the brushes must be altered.—Eugene Brown.

[57132.]—**Electro-Motor.**—The reversal of the direction of the current would not reverse the direction of motion, nor would it injure the machine in any way.—S. Bottone.

[57133.]—**Removing Tin from Scrap.**—Numberless methods have been proposed for effecting this; but, for the most part, with but indifferent success. The following are probably the most promising: 1. Beck's system. The sheet scraps are placed in a stout sheet-iron tank. To each cwt. scrap are added 6lb. flowers of sulphur, 10lb. caustic soda, and a sufficient quantity of water. Steam is introduced by means of a suitable pipe into the tank, and in this way the whole is boiled for 30 minutes. The liquor is then filtered, evaporated to dryness, and the mass, ignited with excess of air, is lixiviated with water. Stannate of soda and sulphate of soda are crystallised, and their different degrees of solubility permitting of their separation. 2. Largue's method. The scraps are mixed with finely powdered charcoal and half per cent. of salt, and placed in a kettle that can be closed, supplied with a horizontal perforated diaphragm in the middle. The upper portion is then heated red-hot, while the lower is cooled with water, when the tin melts and runs through. I fancy this latter method is patented, but I am not certain. A very simple method was suggested by a correspondent of ours some years ago which had succeeded with him on a small scale (see letter 16929, p. 605, Vol. XXX., from Mr. Fahrig, Electrician, of Southampton). He washed the scraps in dilute sulphuric acid (1 acid to 30 water) and then placed them in an earthenware vessel (a cylinder to revolve), covered them with mercury, agitated them well for one hour, and then collected the united mercury and tin, which of course could be easily separated. I shall be glad to hear if any of "ours" have tried this, and how they succeeded.—Percy W. Stanley, 119, Manchester-road, Poplar.

[57133.]—**Removing Tin from Scrap.**—"M. F. K." wants "full particulars." He will find them in back volumes, but any commercially successful process is patented.—Video.

[57134.]—**Easton's Syrup.**—This is the "syrup of phosphate of iron, with quinia and strychnia." The dose is one drachm. It is a fine brain and nerve tonic. Recipe (gratis) by post, if desired.—Percy W. Stanley, 119, Manchester-road, Poplar, E.

[57135.]—**Varnishing Fancy Woods.**—Rub the work over with some patent knotting on a piece of rag two or three times; when this is hard, varnish again, and you will find it all right.—W. Stanyer.

[57136.]—**Problem.**—Since area × height = volume, and $a = \frac{7}{288}$ sq. ft., and $v = \frac{252}{62 \cdot 5} = 4 \cdot 032$ c. ft., $\therefore \frac{7}{288} h = 4 \cdot 032$, $7 h = 1161 \cdot 216$, $h = 165 \cdot 888$. Rate of flow per hour $= 165 \cdot 888 \times 60 = 9953 \cdot 28$ft. per hour.—Bunsen.

[57136.]—**Problem.**—252lb. = (252 × 16) 4,032 ounces = 4·032 cube feet per minute. $\frac{3 \cdot 5}{144} = 0 \cdot 0243$ sq. ft. = sectional area of pipe. Let $x$ = velocity of water per minute, then $0 \cdot 0243\, x = 4 \cdot 032$. Hence $x$ = 166ft. nearly = velocity per minute. ∴ velocity per hour = 166 × 60 = 9,960ft. = 1·886 miles.—J. E. G.

[57136.]—**Problem.**—As I cannot say whether "Judy" means a pipe 3½in. bore or 3½in. area, I have worked the two out for him. A gallon of water weighs 10lb., hence $\frac{252}{10} = 25 \cdot 2$ galls. discharged per minute. A foot length of a pipe 3½in. dia. or bore contains $3 \cdot 5^2 \times \cdot 034 = \cdot 416$ galls., then $\frac{25 \cdot 2}{\cdot 416} = 60 \cdot 57$ft. velocity per minute, and $60 \cdot 57 \times 60 = 3634 \cdot 2$ft. velocity per hour. A pipe 3½in. area:—$3 \cdot 5 \times 12 = 42$ cubic inches in a foot length. Therefore, the 25·2 galls. delivered per minute, multiplied by 277·274, the number of cubic inches in a gallon, and divided by 42 cubic inches $\frac{25 \cdot 2 \times 277 \cdot 274}{42} = 166 \cdot 36$ft. velocity per minute, and $166 \cdot 36 \times 60 = 9981 \cdot 6$ft. velocity per hour.—D. T. W.

[57136.]—**Problem.**—252lb. per minute would equal 252lb. × 60 per hour = 151,20lb. 1 cubic foot of water weighs 1,000oz.

$$= \frac{1000}{16} \text{ lb.} = 62\tfrac{1}{2}\text{lb.}$$

$$3\tfrac{1}{2}\text{sq. inches} = \frac{7}{2} \times \frac{1}{144} \text{ sq. feet.}$$

$$\therefore \text{velocity per hour of water}$$

$$= 15{,}120 \times \frac{2}{225} \times \frac{2 \times 144}{7}$$

$$= 5530 \cdot 6. \text{ Ans.}$$

—Nester.

[57136.]—**Problem.**—252lb. pass per min.; 151,20lb. pass per hour; 241,920oz. pass per hour; 241·920 cub. ft. pass. per hour. There are $\frac{7}{288}$ sq. ft. in 3½ sq. in. $241 \cdot 92 \div \frac{7}{288} = \frac{24912}{100} \times \frac{288}{7} = 9953 \cdot 28$ft. per hour.—Ernst Siemens.

[57138.]—**Removing Tin from Scrap.**—No subject has perhaps been so thoroughly exhausted as this one, upon which "M. F. K." desires information. I would strongly advise him to procure and peruse an article on the subject in the *Journal* of the Society of Chemical Industry, for May, 1885, and to note carefully the criticism at the end of it. As a supplement to that paper, and as a matter of general interest, I subjoin a note of most of the processes that have been proposed and patented during the last twenty years.

English Patent List.

1866. Newton, 1,207. Converts the tin scrap into steel.
1871. Becks, 286. Employs it for precipitating copper.
1872. Morton, 1,739. Removes the tin by dissolving in hydrochloric acid.
* 1872. Morton, 3,676. Removes the tin by dissolving in hydrochloric acid.
* 1873. Gutensohn, 258. Removes the tin by dissolving in hydrochloric acid.
1873. Robinson, 1,708. Removes tin by amalgamating it with mercury.
1873. Hanberg, 2,775. Removes tin by amalgamating it with mercury.
* 1873. Zenger, 3,384. Removes it in a bath of caustic nitrate and chloride of sodium.
1873 Haseltine, 4,070. Dissolves the tin in hydrochloric acid and the iron in aqua regia.
1874. Stuart, 1,276. Treats it with acid and air to yield tin and ammonium salts.
* 1874. Browne, 1,692. Heats in retorts with salammoniac.
* 1874. Morton, 4,285. Liquates out the tin by heating in a chamber with a grating.
* 1875. Clark, 927. Heats the scrap with salt in closed retorts.
* 1875. Morton, 1,471. Heats to liquate the tin in a reverberatory furnace.
1876. Madge, 3,160. Amalgamates with mercury in revolving barrels with gravel.
1876. Parnell, 3,183. Dissolves the tin by sulphide solutions.
1877. Wallbridge, 1,346. Moves the scrap progressively through a hot electrolysing bath.
* 1877. Gutensohn, 1,901. Dissolves in hydrochloric acid, adding ammonia and cupric sulphate.
* 1878. Edmunds, 1,348. Blisters the tin by heat, and separated by a hydro-extractor.
1878. Siegler, 2,851. Dissolves in hydrochloric acid, and removes iron by prussiate of potash.
1879. Reid, 4,700. Oxidises by calcination, and separates the tin by grinding.
1879. Gutensohn, 4,879. Dissolves in hydrochloric acid, and precipitates by electrolysis.
1880. Biggs, 321. Dissolves by acids, and precipitates the tin by sulphuretted hydrogen.
1880. Gutensohn, 4,259. Heats to redness with phosphate of alumina.
1881. Gutensohn, 3,772. Heats in a revolving cylinder with sand to scour off the tin.
1882. Schultze, 777. Dissolves the tin by plumbate of soda.
1882. Barlow, 1,576. Dissolves by hydrochloric acid in revolving cylinders.
1882. Beeks, 3,731. Dissolves in acid and precipitates with chalk.
1882. Abel, 4,400. Employs plumbate of soda and granulated iron to scour it.
* 1883. Laird, 3,952. Employs caustic soda and an electric current.
1883. Cleaver, 5,033. Immerses the scrap in acid or soda with an electric current.
1883. Price, 5,849. Employs caustic soda with an electric current.

1884. Price, 2,119. Employs caustic soda with an electric current.
1884. Poensgen, 4,684. Dissolves in solutions of alkali with nitre.

Those marked with an asterisk received provisional protection only.—H. B. F.

[57139.]—**Amateur Modeller.**—You ought to be the best judge of your own capabilities, and needs. Of course, a planing-machine is not an easy thing to make; but why not tackle a lathe, or an engine, a bench, a tool-box, a dynamo, or some one out of the hundreds of things which have been described in the "E. M." Other things besides planing-machines will be described in the "Amateur Workshop," drills, and a shaper, possibly a metal-turning lathe, and some minor tools, and out of these you may find something which will suit your requirements.—J. H.

[57139.]—**Amateur Modeller.**—Is this querist a dabbler with clay or wax, or is he a mechanical modeller? In the latter case I would gladly help him in any way I can. If he amuses himself with clay or wax I fear my education, being only elementary on those subjects, would not admit of my being of much use to him. My services would be quite at his service; but I am not a "dab hand" at clay.—Invicta.

[57139.]—**Amateur Modeller.**—If "Simpleton" will make known what his inclinations and tastes are mostly disposed for in manipulation, possibly I may be able to suggest something in the way of model-making both pleasing and useful. In fact, I am disposed to lend something to make a copy from. Meantime, I certainly recommend him to make an effort to join the Amateur Mechanical Society, feeling sure some of its members would gladly acquiesce likewise.—E. F. Baker.

[57140.]—**Safe Load.**—In what position is this structure to be fixed? If it is a girder, what is the span, which way up, and what is the thickness of the plates 6ft. long? Or is it a column, and what its height?—J. S. C.

[57141.]—**Gas-Engines.**—I think Mr. W. Bundy is right in saying his drawings would interest a good many readers. I, for one, should very much like to see them.—G. G.

[57141.]—**Gas-Engine.**—To "Invicta," "J.H.," and Others.—Whilst I have not sufficient evidence before me to pass a positive opinion, yet several points named by you are so clear that they are dealable with. I have heard of this Rogerson engine; but, not having the particulars at hand, I cannot give more than a passing opinion. I would, however, ask you the practical question whether you have seen the engine at work, and satisfied yourself that it does do its work on a reasonable gas consumption. I mention this because the heating of the new charge by the old hot products has been tried and put in actual practice by several patentees — notably by Butcher. The theory is right, if it were possible. But no practical arrangement has yet come to my notice, nor do I expect to see such; because the only right way of doing it is by absorbing heat from the waste gas after the gas and air have left the air-pump cylinder. The effect of heating the feeder or air-pump cylinder is most decidedly bad, so much so that one well-known patentee actually jackets his air-pump with water; whilst another makes it of such proportions that the heat due to compression can be thrown off. If the other arrangements be right, the abolition of the hot jacket to the air pump would considerably increase the efficiency of the engine as a whole. Admitting, and releasing, and firing the charge by slots passed over by the piston are not new, although the arrangement you speak of may be. Of that, until I saw it, I could not give an opinion. Bessel's patents cover the system of forcing in air to cool the cylinder from the front part or air-pump, a gland being used. My own suggestion is that, if the drawing can be either published, or if you like at any time to take my private opinion—the address column will give you the necessary channel. Either the patentee must be *very* modest, or he has not satisfied himself on certain points, if he wants only 20s. per engine. And this does not incline me to think that it is a practicable engine. There are also several other points on which I could pass opinions; but in the absence of drawings it would not be fair to hazard what one may think. Can you tell me the number, date, and year of this patent, as it would save me searching back for it?—Invicta.

[57142.]—**Planing Machine.**—With the exception of lathe planers, I have only seen one treadle machine, and that is at the Inventions, next to Evans's and Holtzapffel's stands. I did not examine it sufficiently to be able to tell you how it is worked, neither could you make it, because the machine is patented. It is sold by Selig, Sonnenthal, and Co., and is advertised in the English Mechanic for July 24th.—J. H.

[57143.]—**Dr. Eder's New Sulphite of Ammonia Developer.**—Answered last number, page 453.—A. R. F.

[57144.]—**Bright Silver Plating.**—The articles should first be plated in the ordinary way and then finished in a bath, to which a little bisulphide of carbon is added. The bisulphide should be mixed with a little of the cyanide of silver solution before adding to the bath. The solution is liable to spoil by keeping.—Eugene Brown.

[57145.]—**Gas-Engine.**—It seems strange that this number of the "E. M." should be so prolific of "gas-engine" queries. In reply, the Hutchinson patent, under which the engine you have was made, is No. 5471, 29th December, 1880; it comes under claims 1, 3, 4, and 6. You will find that the light is drawn into the cylinder to ignite the charge through a small aperture. Covering this aperture, and also an auxiliary gas supply, should be a little flap valve. This is either gone altogether, or is stuck fast, and hence allows the flame to be blown out. After standing so long, you should have had the parts cleaned and replaced by a competent man before starting, as the valves throughout are no doubt out of order. It is possible they were never right, as some buyers have told me. Be that as it may, I have myself seen and had running Hutchinson's engines, and the only fault I found with them was that a water jacket was wanted and was not there. If I were near you I would get it going, I feel sure, as the system is right enough, and those I have had to do with for intermittent work ran well enough, because time to cool was then given.—Invicta.

[57149.] — **Brightening Small Goods.** — Bisulphide (not bisulphate) of carbon is the modern name for what used to be called, after Lavoisier's plan, "bisulphuret." The strict scientific name, as adopted by the Publication Committee of the Chemical Society, the highest authority in existence on chemical nomenclature, is "carbon disulphide." We still speak familiarly of carburetted, phosphuretted, and sulphuretted, hydrogen; but these terms are gradually being replaced by the more scientific appellations of "hydrogen sulphide," &c. The carbon disulphide is an extremely volatile liquid, highly inflammable, and usually possessing a most disagreeable odour, somewhat suggestive of stale cabbage water. If this is what your chemist has given you, have the article recommended.—Percy W. Stanley, 119, Manchester-road, Poplar, E.

[57149.]—**Brightening Small Goods.**—It is the bisulphide of carbon you require; bisulphuret is the same thing. It is easily recognised by its smell resembling rotten eggs.—Eugene Brown.

[57150.]—**To Mr. Bottone.**—Your connections are wrong. You should couple from one brush to one coil of field magnets, round the other field magnet to the lamp, back from lamp to other brush. If all were well, you might light seven or eight 10's, or four or five 20's, with such a machine. Provided the insulation and connections be right, the other little points mentioned would not vitiate the machine.—S. Bottone.

[57151.]—**Problem.**—Let £$a$ = interest now accumulated; £$b$ = weekly interest of the sum; £$c$ = a workman's weekly wages; $x$ = time required (in weeks). Then—

$$a + 11\,b = 165\,c$$
$$a + 5\,b = 155\,c$$
$$a + x\,b = 9\,x\,c$$

Subtracting the second equation from each of the others we get $6\,b = 10\,c$, and $(x - 5)\,b = (9\,x - 155)\,c$. Therefore—

$$\frac{3}{x - 5} = \frac{5}{9\,x - 155}$$

$$\text{Therefore}\quad 27\,x - 465 = 5\,x - 25$$
$$\text{whence}\quad 22\,x = 440$$
$$\text{and}\quad x = 20 \text{ weeks.}$$

—T. Watt.

[57151.]—**Problem.**—Let weekly wages = $x$.

$$15 \times 11 \times x = 165\,x = \text{sum paid}$$
$$31 \times 5 \times x = 155\,x = \text{sum paid.}$$

Let A = number of weeks elapsed
R = rate per cent.
P = principal.

$$165\,x = \frac{P\,R}{100} \times \frac{A + 11}{52} \quad (1)$$
$$155\,x = \frac{P\,R}{100} \times \frac{A + 5}{52} \quad (2)$$

equate values of $x$:

$$31\,(A + 11) = 33\,(A + 5)$$
$$2\,A = 176$$
$$A = 88 \text{ weeks.} \quad (3)$$

let $y$ = number of weeks required, then

$$9\,x\,y = \frac{P\,R}{100} \times \frac{88 + y}{52} \quad (4)$$
$$165\,x = \frac{P\,R}{100} \times \frac{99}{52} \quad (1 \text{ and } 3)$$

equate values of $\overline{P\,R}$:

$$165\,(88 + y) = 99 \times 9\,y$$
$$165\,y + 14520 = 891\,y$$
$$726\,y = 14520$$
$$y = 20 \text{ weeks.}$$

—Ernst Siemens.

[57153.]—**Problem.**—Let $x$ = original amount of grass per acre, let $m\,x$ = daily growth per acre. If 15 oxen consume 5¼ acres in $4\,y$ days, then 1 ox consumes $\frac{7}{20}$ of an acre in $4\,y$ days, and 1 ox consumes $\frac{35}{124}$ of an acre in $3\,y$ days—

$$\therefore \frac{7\,x}{20} + \frac{7\,m\,x\,y}{5} : \frac{35\,x}{142} + \frac{105\,m\,x\,y}{124} :: 4\,y : 3\,y.$$

$$\text{Hence}\qquad m\,y = \frac{7}{72}$$

If 20 oxen consume 6¼ acres in $z$ days, then 1 ox consumes $\frac{5}{16}$ of an acre in $z$ days.

$$\therefore \frac{7\,x}{20} + \frac{7\,m\,x\,y}{5} : \frac{5\,x}{16} + \frac{5\,m\,x\,z}{16} :: 4\,y : z.$$

Hence, substituting for $m\,y$—

$$z = \frac{24\,y}{7}$$

Similarly we find—

$$z + 3 = \frac{27\,y}{7}$$
$$\therefore \quad \frac{3\,y}{7} = 3$$

$\therefore 3\,y = 21$ days, which is the time required.—T. Watt.

[57153.]—**Problem.**—The time varies as the number of acres, and inversely as the number of oxen. Let $x$ = number of days in which one ox eats one acre—

$$\text{Then time for } 20 = \tfrac{25}{4} \times \frac{x}{20} = \frac{5\,x}{16} \quad \ldots\ldots\ldots\ldots(1)$$
$$\text{,,}\qquad \text{,,}\qquad 22 = \frac{15\,x}{44} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(2)$$
$$\frac{15\,x}{44} - 3 = \frac{5\,x}{16}$$
$$\frac{15\,x}{44} - \frac{5\,x}{16} = 3$$
$$x = 105{\cdot}6 \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(3)$$

Therefore the time for $15 = \tfrac{21}{4} \times \frac{x}{15} = \frac{7\,x}{20}$, and by hypothesis the 31 oxen take ¾ of this. $\tfrac{3}{4} \times \tfrac{7}{20} \times 105{\cdot}6 = 27{\cdot}72$ days.—Ernst Siemens.

[57154.]—**Horse Taming or Breaking.**—It is evident that in your case the horse is at present master of the situation; now you must reverse the order of things—you must be master. If you are nervous, dispose of the animal, and purchase something warranted quiet. If not, stick to him, and try by kindness and persuasion to get him quiet. There are plenty of men used to horses employed in cabyards, 'bus, and tramyards, that for a small consideration would go out with you and help to keep him quiet, and after a few lessons you would be able to drive him by yourself. Of course, there are lots of horses that are incurable. In your case perhaps he does not have sufficient work; but there are so many reasons for a horse kicking besides viciousness, that unless I saw him in harness I could not advise. About the year 1858 a Mr. Rarey, an American, visited this country, and was very successful with vicious horses. He published a book explaining his system, which, I think, is to be had from Routledge and Co., Broadway, E.C. However, I know that it is worth trying; so purchase the book and tame your horse.—J. H. F.

[57154.]—**Horse Taming or Breaking.**—You cannot have this query answered after the manner of a recipe. It is quite evident that the horse is exactly what you have made him to be by your improper treatment, and it is not likely that with the best advice you will be able to improve him. What is required to be master of a horse is kindness, firmness, fearlessness, a perfect mastery of one's own temper, and no unfair play. This, with a moderate amount of perseverance, will insure success, but very few can practise it thoroughly. I do not consider any man a good horseman unless he can go into a great park and take up his turned-loose horses as easily as if they were tied. Should be happy to give you a lesson gratis if I lived near. I would never allow a circus man to take a horse of mine out of my sight, and I know something of their practice.—Old Ploughman.

[57154.]—**Horse Taming or Breaking.**—In reply to the latter part of this query, I may inform "M. H. J." that there is a full description (illustrated) of Rarey's method of horsebreaking in "Stonehenge's" book on the Horse. I should be happy to lend my copy of the book to "M. H. J." if he will take care of it and return it in a reasonable time, and will advertise his address.—Eques.

[57158.]—**Bird Taming.**—Having been successful in taming wild birds, I send my mode of treatment for the benefit of "W. P." and others who may be interested. First, treat your bird kindly, avoid frightening it, and do not speak in an angry tone. Secondly, take it into a dark place every day; put your hand into the cage and place the forefinger against its breast. The bird will step on to the finger. Now bring it gently out of the cage and place the forefinger of your other hand against its breast as before, when you will find it will step on to the other finger. Keep on repeating this, first one finger and then the other, for at least five minutes, and keep on with this treatment once a day, or oftener, if convenient, speaking kindly as you proceed. After a time you will find that the bird may be let out of the cage and will perch on your head, hands, or anywhere without the slightest fear.—W. Potter.

[57159.]—**Watch Query.**—The verge escapement is a most unreliable one at the best, and one which is governed most of all by the pendulum (or hair) spring. "Caribbean," no doubt, has his spring too stout—too strong for the watch, or it may be caused by the escapement being too shallow. If the spring has not been all let out from the stud, put it out, and if it still gains, it will be necessary to have a weaker one. This can be judged from the weight of the balance on the spring—take one which is stretched a trifle further out when the balance is suspended from it. Of course it must be put on to coil the right way, so that the first coil passes through the regulator. If this is not sufficiently explicit, shall be happy to further explain. —Escapement.

[57159.]—**Watch Query.**—The number of beats per hour must first be ascertained; say, for instance, it 's 16,200: that would be nine beats or vibrations of balance in two seconds. Find the right size spring shall be, lay it on balance arms, balance lying verge upwards, and gently press collet down on it sufficient to hold spring. Take hold of spring so many turns from outside coil as is right size, and hold by the tweezers, balance suspended. With a touch set it vibrating, and count. Thus you can try any number of springs without troubling to pin them in, shorten them, or damage in any way. Of course, the beat may be any other number than above quoted. Whatever it is, you must reckon the number of beats it would be in any given number of seconds most convenient.—Peganredstuff.

[57163.]—**Employment at the Arsenal.**—Only by applying to the superintendent or manager of the department, unless you can obtain a letter of recommendation from somebody who is a somebody.—E. G. M.

## UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

**Unreported Brake Failures.**—At the meeting of the Executive Committee of the Amalgamated Society of Railway Servants held in London last week, the general secretary stated in his report that, having drawn the attention of the Board of Trade to brake failures which had not been reported by the companies to the Board, the reply he received was a very unsatisfactory one, and from which it would appear that the Board of Trade have no intention of putting the law in force against those companies. The executive committee passed the following resolution thereon:—"That this committee strongly urge the Board of Trade to put in force the provisions of the Railway Returns (Continuous Brakes) Act, 1878, in all cases wherein default has been made by companies omitting to make the returns, or where same, when made, are inaccurate, or, to use the words of the Act, 'false in any particular.'" It was resolved that the committee recommend to the annual general meeting that Clement E. Stretton, Esq., C.E., become vice-president of the society.

From W. Wesley and Sons, of Essex-street, we have No. 66 of the Natural History and Scientific Book Circular, which gives the titles of works they have for sale connected with entomology, botany, ornithology, fishes, &c.

## QUERIES.

[57164.]—**Trigonometrical.**—From the summit of a tower, whose height is 108ft., the angles of depression of the top and bottom of a vertical column, stand on a level with the base of the tower, are found to be 30° and 60°. Find the height of the column. Will some mathematician kindly give me a simple trigonometrical solution of the above?—Chas. A. Whatmore.

[57165.]—**Course of the Wind.**—Within the last 24 hours, the wind has backed from E. through N. W. and S., returning again to E., with a barometer absolutely stationary, and without any atmospheric disturbance whatever, save some fog at daybreak, the sky throughout the day being mostly cloudless. Meteorologists say that a complete revolution round the compass, if the wind is in the same direction as the sun, occurs but a very few times in the course of the year. Will some correspondent who is conversant with the subject, say how often a complete revolution in the opposite direction (backing against the sun) as in this case, occurs? I have observed the weather and course of the wind for many years, and have never observed such an occurrence within anything like the same space of time?—M. A., Gloucester.

[57166.]—**Model Well.**—Will any of your correspondents kindly explain the following? A friend has a model ebbing and flowing well in his garden; the water supply is from a large fountain tank, out of which projects a tap to regulate the flow into a cylindrical leaden cistern from near the bottom of which projects the siphon. The bore of the supply pipe being much smaller than that of the siphon, how is the latter completely filled with water at the bend, and thus siphon action made commence?—lead cistern about 2ft. deep, by 12in. diameter.—H. A.

[57167.]—**Wood Planer.**—Can any correspondent give me a detailed account or description of the Daniels wood planer, with a diagram if possible?—Improvement.

[57168.]—**Separating Oil from Tallow.**—Will any kind reader please inform me how I might obtain the oil from beef tallow?—Improver.

[57169.]—**Boiler Construction.**—I should feel obliged for any information as to the correct dimensions of vertical, from one horse-power up to six horse-power, and the best way to construct the same. I should be glad to know the number of tubes, and the best way to put them in, and the sizes of tubes for each boiler, and the thickness of plates. Are there any works on the subject?—T. M. S.

[57170.]—**To Mr. Bottone.**—Will you give particulars "how pure P is prepared in an atmosphere of $CO_2$." A diagram of apparatus would greatly please.—Magi.

[57171.]—**Hardening Punches.**—What is the best way of hardening punches for punching the nail-holes in horseshoes? I am a smith by trade, therefore I happen to know a little about the working of steel, and have tried various ways for hardening them, but cannot get them to stand. I think the difficulty lies in the shape of the punch, it being taper, therefore there is no clearance at the back of the punch, which causes it to jam in the holes, so you will see by that that there is a great strain on the punch: if they are too hard they break, and if they are not, they shove up. I must tell you they are steel shoes, and the punches work in a machine, and the shoes are punched cold. The size of the punch is 3-16th to ¼th, at point tapering up to ⅜th.—H. F.

[57172.]—**Dynamite for Quarrying.**—Could any reader tell me if dynamite would be better than rock powder for getting out stone, and how used? Also if there is a quicker way for a man with means limited to get water out of quarry, than by a common stand pump about 15ft. lift?—Quarryman.

[57173.]—**Easing Force Pump.**—My force pump, with a lift about 30ft., goes tremendously hard. Could I make it easier by having an air vessel put to it?—Rector.

[57174.]—**Steam Canoe.**—To "Invicta" or Others. —Being about to build a canoe, 12ft. or 15ft. long, and 3ft. wide, I am desirous of fitting a screw engine into it. Could the new steam motor, about which you have spoken, drive it?—if not, can you advise me as to a boiler and engine that will work at a pressure beneath the atmospheric? Any information will be thankfully received.—K.

[57175.]—**Sand-Blast.**—Could any of your correspondents give me a description of a sand-blast apparatus for working against a vertical surface? Also of a suitable blower for the above to be worked by manual labour.—A. Frankish.

[57176.]—**Microscope Lamp.**—I have a student's monocular, which I intend to fit with a small incandescent lamp. Will some reader kindly give a description, with a sketch, if possible, of a stand suitable for the purpose, and also name the best kind of lamp to use? I shall employ a bichromate battery.—J. B.

[57177.]—**Soldering.**—I have a deal of soldering to do, but do as I will, I can't keep the solder on the iron. Will someone kindly tell me how to proceed, so as to make a good job of it?—New Beginner.

[57178.]—**Clutch.**—Will some reader kindly give sketch and description of clutch, suitable for treadle of foot-lathe?—Clutch.

[57179.]—**Leather Scrap.**—If this lies exposed to the weather, say for a year or so, I shall be glad to know whether it will have lost any of its nitrogen?—Scrap.

[57180.]—**To Mr. Bottone.**—Would you be good enough to explain, either in words or by diagram, how the wire is wound on a Siemens H laminated armature? Do not the projecting ends of the central shaft interfere with the lapping of the wire over the ends of armature?—Perplexed.

[57181.]—**Heating Greenhouse.**—Will any of "ours" kindly enlighten me on the following?—I desire to put heating apparatus into small greenhouse 10ft. by 6. I am told the slow-combustion stoves do not answer the purpose, and that I shall require the hot-water pipe affair. Is there any real practical advantage in these pipes over the combustion stoves? Should be glad to have the opinion of anyone who has had experience in this matter.—Thermo.

[57182.]—**G.N. Locomotives.**—(1) What are the chief dimensions of the "single drivers" of the G.N.Ry.? I should particularly like to know the diameters of the wheels, the wheel base, the length of the boiler, and the length of the connecting-rods. (2) Have these engines the largest driving-wheels in England? If not, where are they to be found?—V. J. B.

[57183.]—**Planing Machine.**—Some time ago I had a planer made to plane 20in. by 10in. square; it was fitted with a pair of clamps 2in. high, and a pair of angle plates 3in. high. I find that the latter tilt up and are forced apart by their screws when any work is placed between them, the screws being placed ½in. from top of plates. I complained about this, and am given to understand that I must not expect to plane more than 4in. high on so small a machine. Can "J. H.," or some other, tell me how to make suitable clamps, &c., that will not tilt up or let the work slip away? I may say I have planed the full height of the machine without its trembling in the least degree, but the work always slips away after three or four cuts.—F. Shakespear, Dresden.

[57184.]—**Headstock.**—Can I make a back-geared headstock with only one arm for back-gearing? All the wheels would be behind the pulley. I propose to make a boss on arm 2in. long for eccentric to work in, the wheels to be carried on a short stud. Can this be done, and what alteration needs the pattern?—F. Shakespear, Dresden.

[57185.]—**Dynamo.**—To Mr. W. H. Eaves, Coventry.—Kindly permit me to tender you my warmest and most sincere thanks for your prompt and courteous reply to my inquiries respecting construction of dynamo; but, being a little disappointed with the prospective capability of such machine when finished—viz., four 20-c.p. lamps—I suspected that there must have been an error somewhere, and consequently I referred back to my query (No. 57068), wherein I found I had blundered very much by stating that my armature was "two-thirds less," &c., whereas I should have stated it to be "three-fourths of the size given by you for a 30 lighter." Therefore, to avoid further mistake, I beg to give you exact size of my armature, which is 5 13-16in. in length by 5 13-16in. external diameter by 3¾in. internal diameter. Will you kindly give me the needful information asked in my previous letter with this correction? Also, please say about what h.p. will it require to run it? Hope you will pardon me for thus giving you further trouble.—Cymro Gwledig.

[57186.]—**Astronomical.**—Will "F.R.A.S.," Mr. Franks, or Mr. Sadler, kindly give me the exact places for 1885 of the following objects in the late Mr. Webb's book, fourth edition, as I cannot find them from his descriptions? I think it a great drawback that in the last edition the places are only given to the nearest minute of time. T Coronæ. B.A.C. 6624, 7001, 7219. Σ Neb. 6 Tauri Poniatowski. H 5112 Sagittarii. Bu. 142 Aquilæ. H 1470 Cygni. B 658 Cassiop.—J. W. Ruthven.

[57187.]—**Repairing Marble Ornament.**—Will anyone inform me how to dissolve plaster of Paris so that I can move a portion of a marble ornament joined together with it? Of course, it must be something that will not injure or discolour the marble, which is white. I have tried soaking in cold water for over four hours, which had not the slightest effect, the plaster being thick, and in so doing the gloss on the ornament came off up to the water-line. Could anyone inform me also what this gloss is composed of, or how to put it on?—W. E.

[57188.]—**American Popcorn.**—Can any reader give the recipe for colouring and flavouring above?—W. L.

[57189.]—**Income Tax.**—A firm consisting of two partners makes £280 in one year. Is the firm liable for income tax, although the income of each partner is under £150?—Glasgow.

[57190.]—**L.B. and S.C.R. Engines.**—Can any of your readers give me full dimensions of the "Gladstone," L B. and S.C.R.; No. 605, G.E.R.; and the "Lord of the Isles," G.W.R?—Piston Rod.

[57191.]—**Tuning Clock Bells.**—To "Clerkenwell Clockmaker," or Others.—Will someone give me a few hints as to tuning bells for a Westminster chime, or on tuning bells generally? How much is a bell capable of being altered in pitch—say a 8in. ordinary clock bell? Would the wire coils, the so-called "cathedral-toned gongs," be of use for this purpose?—Roi ne Puis, Souza je Suis.

[57192.]—**Drills and Taps.**—Will any of our readers give me a scale or table of sizes of drills for drilling holes for tapping, say, from ¼in. up to 1½in. in bolts, and from ¼in. up to 1in. in piping?—Drills.

[57193.]—**Balance Staff.**—Would anyone give me instructions for working watch turns—say the whole process of fitting balance staff or cylinder? How is the staff fixed in turns, &c.? Should watch or clock pinions be oiled?—British Workman.

[57194.]—**Punch.**—To "Invicta."—Will you kindly tell me how I can make a punch to work by lever to punch holes up to 5-16in. diam., through ¼in. copper and brass?—F. Shakespear, Dresden.

[57195.]—**Iron Rusting.**—What kind of paint can I use to prevent the bright parts of a machine becoming rusty? The paint must be easy to remove; the white lead and oil sets on the iron too hard.—F. Shakespear, Dresden.

[57196.]—**Preparation for Hair.**—With reference to letter 24530, can any correspondent say whether Dr. Rohe's preparation for the hair can be obtained in England, or the German soft soap used in it?—Emu.

[57197.]—**Watch Springing.**—Can any of the watchmaking correspondents of the "E.M." kindly give me directions how to order a new mainspring, the size and strength of the broken one? I have a mainspring gauge with strength gauge. Can anyone tell me when I take out the broken mainspring how to take the proper size and strength of it by the gauges, so that when I send to the material dealers that the sizes I give will be intelligible?—Amateur Watch Repairer.

[57198.]—**Valves in Compound Engines.**—To "Invicta."—Will you kindly let me see the sketch of the valves of a compound engine that you willingly offered "Boolie" if requested by him ?—F. Hawkins.

[57199.]—**Gas Engine.**—Would "Invicta," or anyone interested in gas-engines, kindly give a table in these columns to get the horse-power of a gas-engine ? I have a 2 man-power gas-engine which will not maintain the power of a boy at nine years of age, and I wish to reckon it up.—G. G.

[57200.]—**Indicator Diagrams.**—Will any of your readers kindly inform me how to calculate the indicator diagram of three cylinder engines ? What I want to know is, when I get the mean pressure of each cylinder, do I add the three means together and work them out in one sum, or do I work the mean pressure of each cylinder out by itself ? Stroke of engine, 44in. ; 50 strokes per minute ; bore of two low-pressure cylinders, 19in. ; high-pressure, 13¾in. ; boiler pressure, 78lb. Average pressure on each side of pistons—

| | | lb. |
|---|---|---|
| Low-pressure | Left back | 28·6 |
| Low-pressure | Left front | 25·2 |
| Low-pressure | Right back | 27·0 |
| Low-pressure | Right front | 24·2 |
| High-pressure | Right front | 47·4 |
| High-pressure | Right back | 66·2 |

—Young Beginner.

[57201.]—**Violin Strings.**—Could any reader of the "E.M." kindly tell me what is the relative thickness of each string upon an English 3-string double-bass to bring out the finest tone, and the probable cost of the same ? Also, the distance of sound peg from the foot of the bridge ? I wish to re-string my instrument as the present one makes my fingers sore, and I am informed they are too thick. Will someone oblige ?—Contra.

[57202.] — **Driving Cotton Machines by Electricity.** — I am intending turning two cotton machines by electricity. The machines will require about 1-h.p., and are situate about 100 yards from the motive power. The information I want is (1) What will the cost of running by electricity be compared with steam per hour ? (2) What will a 1-h.p. dynamo cost ? (3) What will the wire cost to transmit the power per yard ? (4) How is the power to be applied to the machine ?—will it require copper pulleys ? Any other information relative to electricity used as a motive power I shall be glad of.—Cotton.

[57203.]—**Numbers of Locomotives.**—Could any of your readers inform me by what rule the numbers of locomotives are determined, and why they should be changed, as I hear will be done with the "Marchioness of Stafford" ?—V. J. B.

[57204.]—**Sea-Water Aquarium.**—I am thinking of constructing an average-sized sea-water aquarium. Would any reader give me any hints about this ? (1) The kind of fish and plants most suitable ? (2) How long can the water be kept without being changed ?—(I heard of one being kept five years without change of water.) (3) Would the aquarium require any zinc top ? (4) What sort of place it should be kept in, and any other useful hints ?—Nester.

[57205.]—**Over-dry Leather.**—Owing to the use of a gas stove, the backs of my bound books have become dry, and are apt to crack. Will someone kindly tell me how to remedy the mischief ?—B. A.

[57206.]—**Land.**—What is the legal remedy, if any, in the following case ? I bought a plot of land, paid nearly the whole purchase money on account, and took a receipt for the money (bearing a penny stamp) with a rough plan of the ground thereon. The seller now refuses to give me a title, because he has learnt that I intend to put up a house of about half the accommodation of one that he has since built (and let) on a neighbouring plot. The value has increased ; he would return the money, mine being at the back of his, that is to say, his back door is towards my plot. I don't want to quarrel with him if I can avoid it, and would be thankful for any advice.—Ignorant.

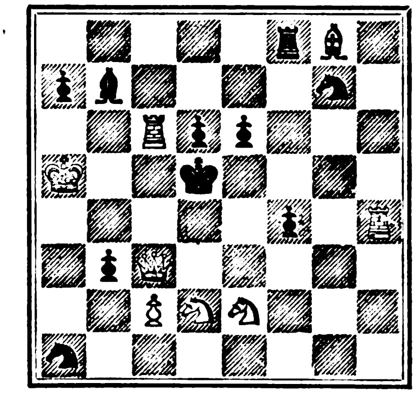
**Colouring Matter of Leaves.**—M. Arnaud, in a note read at the Paris Academy of Sciences, has called attention to the identity established by his researches between the orange-red matter extracted from leaves and carotine. He has found the same solubility in various disolvents, the same crystalline form and the same point of fusion (335° Fahr.) The two substances have likewise the same appearance and the same chemical reactions. They are not nitrogenised, and give birth under the influence of chlorine water to a chlorated composition, which is white and insoluble in water. Husemann has prepared this composition by starting from carotine, and assigns to it the formula $C_{18}H_{20}Cl_{14}O$. M. Arnaud has reproduced it by the assistance of the orange-red substance in spinage leaves, having satisfied himself on this subject by ascertaining the point of fusion (248° Fahr.) Carotine has been studied with great care by Zeise and Husemann, who has established for it the formula $C_{18}H_{24}O$. Carotine is found in the different organs of vegetables. It appears to constantly accompany the chlorophylle. He discovered it to exist in the leaves of spinach (*Spinacia glabra* and *oleracea*), of mulberry (*Morus alba*), of peach (*Persica vulgaris*), of sycamore (*Acer pseudoplatanus*), of ivy (*Hedera helix*), in carrot root (*Daucus carota*), and in large gourds (*Cucurbita pepo*). The simultaneous and constant presence of carotine and chlorophylle in these leaves is doubtless not entirely fortuitous, and it is considered that there must be certain chemical relations between the two substances, of which the details are not known.

## CHESS.

All Communications for this department must be addressed to J. Pierce, Langley House, Dorking.

### PROBLEM DCCCCLI—"The Way the Wind Blows."

*Black.*



*White.* [8 + 10

**White to play and mate in two moves.**

### Solution to 949.

| *White.* | *Black.* |
|---|---|
| 1. Q-K B 2 | 1. Anything |
| 2. Q, R or Kt mates | |

(Six variations.)

### NOTICES TO CORRESPONDENTS.

Correct solutions to 948 by F. A. Vincent (very interesting, but variation 1 B-B 5 omitted—Ed.), E. S., R. A. Bennett, J. A. Miles (a very fine and difficult problem, but if in your main play 1 $\frac{\quad}{\text{K takes B}}$ 2 $\frac{\text{Kt takes P (ch)}}{\text{B takes Kt}}$. — Ed.

To 919 by J. A. Miles (weak), E. S. (but variations not given), F. O'N. H., R. A. Bennett, and Pathologist.

C. C.—Very good for a first attempt. You will soon be able to manage three-movers.

English Mechanic Tourney.—Game between Rev. J. T. Chatto (White) and J. H. Blake (Black).

(King's Knight's Defence).

1. P-K 4, P-K 4 / 2. B-B 4, Kt-K B 3 / 3. Kt-Q B 3, B-B 4 / 4. P-Q 3, P-Q B 3 / 5. Kt-B 3, P-Q 3 / 6. P-K R 3 (*a*), B-K 3 / 7. B-Kt 3, Q Kt-Q 2 / 8. Castles, P-K R 3 (*b*) 9. Kt-K 2, Kt-B sq / 10. K-B 2, K-B 4 / 39. resigns.

### Notes by J. H. Blake.

(*a*) As he intends castling K-side, and Black has not done so, this move is weak as being likely to facilitate an attack by Black's K-side pawns.

(*b*) To support the advance of K Kt-P whenever it may be thought desirable. In another game with the same opening moves, White continued 9 $\frac{\text{Kt-R 2}}{\quad}$ when Black was able to reply 9 $\frac{\quad}{\text{P-K Kt 4}}$ preventing the advance of K B P.

(*c*) Weak : he should retake with B P, when it is not easy to see how White can escape losing a P.

(*d*) If 23 $\frac{\quad}{\text{R takes P}}$ Black ultimately loses his valuable Q P in return for the one gained.

(*e*) Best : for if 28 P takes Q, R takes Q / 29. P takes P, R takes B P / and Black has a winning end game.

(*f*) Better than B sq, on account of the after play.

(*g*) If 32. Q takes K P, P-Q 7 / 33. Q-Q 4, R-K B 4, and wins.

(*h*) Much better than taking at once : e.g. — 36 . . . . . Q takes Q (ch) 37. K takes Q, K-Kt 3 / 38. P-K R 4, K-B 2 or 4 / 39. P-Kt 5, P takes P / 40. P-R 5, P-Kt 5 / 41. P-R 6, P-Kt 6 (ch) / 42. K takes P, P-Q 7 / 43. P-R 7, P Qs / 44. P Qs, and Black has by no means an easy win.

**Holloway's Ointment** is unrivalled for its healing qualities. Printed and very plain directions accompany each pot. It reduces local inflammation, heals ulcerations, and cleanses the surface of wounds. It is invaluable in cases of rheumatism and neuralgia, relieving mucular and nervous spasms, together with cramps in the limbs or bowels.

## ANSWERS TO CORRESPONDENTS.

⁂ *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

### HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

### BACK NUMBERS.

We receive so many queries asking for directions how to make many instruments and appliances which have been fully described in back volumes that we have compiled a list, which we shall insert in this column at intervals, of those most frequently sent, and as the numbers are still in stock, new subscribers should consult the list before sending their questions.

Batteries: Nos. 741.
Bookbinding: Nos. 613.
Copying processes: Nos. 750, 753.
Electric machines: Nos. 628, 759, 840.
Electro-magnets: Nos. 756, 772.
Lacquers: No. 866.
Pattern Making: Nos, 938, 941, 943, 945, 948, 950, 952, 954, 955, 956, 958, 959, 962, 963, 965, 969, 973, 974, 975, 981, 986, 989, 993, 995, 998, 1,000, 1,001, 1,003 1,004, 1,005, 1,009, 1,010.
Silver-plating: No. 890.
Telephones: Nos. 695, 747, 865.
Varnishes: 478, 619, 675, 691, 723, 775.

The following are the initials, &c., of letters to hand up to Wednesday evening, Aug. 5th, and unacknowledged elsewhere :—

J. H. Porter.—Tha Ban.—J. T. M.—Kippo.—George Yarg.—S. Bottone.—Chas. Hosken.—G. Fryer.—J. S. C.—A Fellow of the Royal Astronomical Society.—W. Lane Sear.—W. P. W.—Asterisk.—Subscriber from No. 1.—Rev. J. Pearson.—Rev. T. H. Browne.—David Stephen. — Z. A. — Hiram. — E. S. L.—Manchester Plumber.—Carpenter.—A Constant Reader.—G. Worlands.—Plate Worker. — Busby.—Surveyor.—Western Youth.—Topic.—Dandie Dinmont.—Fred Loundes.—Orderic Vital.

Ar. (It would be alike useless to trouble "F.R.A.S." or to go to the cost of engraving your diagram, inasmuch as the most rudimentary acquaintance with the subject would show you that your idea is radically unsound.)—Tyro. (See Hints No. 4. 2. Nitric acid most likely. The metal is protected by soap or wax. 3. Remove a ring of the bark, clearing it out down to the wood. 4. Gum ; see answer to "Gum" below.)—A Fitter's Labourer. (The methods of cutting out have been described, as you appear to know ; but as to buying the music merely marked out, we suspect you must apply to the dealers in the instruments named. Why not mark it out yourself ?)—Gum. (You would have found the recipe if you had looked through No. 980. Take dextrine 2oz., acetic acid 1oz., water 5oz. and mix. When the dextrine is dissolved, add 1oz. alcohol.)—S. J. (Try the publishers of sporting books, such as Baily and Co., Cornhill.)—A. Horrocks. (Cannot you settle the question yourself by trying how long it will keep ? Surely it depends to a large extent on the weather.)—H. S. H. (You will find a good deal about it in back numbers, and we may possibly have an article about it before long.)—Armourer. (Ebonite is made of indiarubber and sulphur subjected to a temperature above 300° Fahr. It is not easily made "at home," but can be done in a dentist's vulcaniser. Asbestos is a silicate of magnesia ; it ranks as a non-conductor, and, mixed with a hydrocarbon, is known under the name of asbestite, a material sometimes used for cells and for stands of electrical machines.)—E. A. Thomas. (All objects within the cone of rays would be seen ; but only those on a level with the aperture if the range is short. See the indices.)—A Railway Signalman. (We do not know ; but about ten or twelve hours, according to the weather. Lodgings are cheap compared with the usual run of seaside places. Nothing special to be seen.)—Henry Taaffe. (Why not ask the chemical professor himself ? The process could, no doubt, be found in the *Transactions* of the Chemical Society.)—L. Lee. (The plan has its advantages, and has already been tried with partial success in towns where large furnaces are convenient.)—W. Mitchell. (We know nothing of them, and we strongly advise all readers to have nothing to do with "handsome offers" of any kind till they learn more about them. Some of these are, perhaps, genuine affairs, and when advertisements come to us through respectable agents we are unable very well to refuse them, and we have no time to inquire into their real character ; but readers must in all cases exercise discretion, and take no advertisement for granted because it appears in a respectable paper.)

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a [illegible] Wrapper, as an intimation that a fresh remittance is necessary if it is desired to continue the Subscription.

## USEFUL AND SCIENTIFIC NOTES.

**Estimation of Oil in Cattle Cake.**—Having had occasion to estimate the percentage of oil in some samples of linseed and cotton cake, a very simple and effective method of conducting the analysis suggested itself to me, and a description of it may be of some use to analytical chemists. It consists in placing the sample, together with about 50cc. of ether, in a small, well-stoppered bottle, tying the stopper, and leaving the bottle in a vessel of boiling water for fifteen to thirty minutes. The solution of oil is decanted into a small weighed flask, the residue in the bottle washed with ether, and the washings added to the contents of the flask; the ether may then be distilled off, and the residual oil dried at 100° C. A repetition of the process was found to give in no case more than 2mgm. of oil, thus appearing to be far more exhaustive than the method usually employed, which consists in either boiling the sample with ether in a flask fitted with an inverted condenser, or repeatedly drawing cold ether over the cake which is packed in a glass tube, while at the same time it is more expeditious and less troublesome.—*Chemist and Druggist*.

**Salted Runner Beans** are in favour in many parts of the country, and are acceptable in spring for a change. They are gathered when full grown, but not seedy, and are closely packed in earthen jars, and sprinkled with salt as the packing proceeds. Sometimes the precaution is taken to dry the salt in an oven previously to using it, and to spread the freshly-gathered beans out for an hour to render them extra dry before packing. The jars are tied down securely, and stored in any cool and dry place. When the beans are taken out they require to be soaked in cold water for a few hours; they are then cooked whole and served with a little butter. The colour is certainly not good, but the flavour is excellent.—*Amateur Gardening*.

**Regeneration of Nerves.**—"Fresh Researches on the Regeneration of Peripheral Nerves" was the subject of a paper communicated to the Académie des Sciences by M. Vanlair (*L'Union Médicale*, July 11th). If the process of regeneration be studied in the divided sciatic nerve of the dog, after the lapse of several years it will be found that the initial phases of the evolution are accomplished in a definite manner, whilst the final stages are by no means uniform. In all cases the lower extremity of the central portion of the nerve exhibits a proliferation of the marginal zone of nerve fibrils, a disappearance of the axial fibres, and a sprouting of new fibres, which project into a new formation of connective tissue. The whole forms at the central end of the divided nerve a "neuroma of regeneration." The further changes vary in different cases. Sometimes the neuromatous formation remains sterile; it stretches a little distance from the divided end, then becomes thinner, and disappears without giving rise to any nerve fibres. Sometimes genuine nerve fibrils are formed. This organisation, which is often achieved only after a series of fruitless attempts, results in the formation of a longitudinal and systematic arrangement of nerve fibres. The author insists on the importance of mechanical conditions in assisting the regenerative process; the chief mechanical condition is the accurate apposition of the divided ends.

**Every Workman** connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words .. .. .. .. .. .. .. | 2 | 6 |
| Every additional eight words .. .. .. .. | 0 | 6 |

Front Page Advertisements Five Shillings for the first 40 words, afterwards 9d. per line. Paragraph advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

| | s. | d. |
|---|---|---|
| Twenty-four words .. .. .. .. .. .. | 0 | 3 |
| For every succeeding Eight Words .. .. .. | 0 | 3 |

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. | d. |
|---|---|---|
| Sixteen words .. .. .. .. .. .. .. | 0 | 6 |
| For every succeeding Eight words .. .. .. | 0 | 6 |

*** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid: no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday, to insure insertion in the following Friday's number.

## TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve months, Post Free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII., XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., and XL., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words, and 3d. for every succeeding 8 words.*

**Good Value Offered** (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—CAPLATZI, Science Depot, Chenies-street, near British Museum. Established 1862.

Handsome **Pipe Organ**, 7 stops, 1½ octave pedals, hand and foot blower; suit chapel; room wanted. Exchange American Organ or Piano.—WALES, Hemsworth, Yorkshire.

For exchange, one of Shew's ½-plate **Changing** Boxes. Exchange for anything useful in photography.—Address, E. WAITE, Photographer, Radcliffe, Manchester.

Wanted, 4in. back-geared **Lathe-Head**, also Vertical Boiler, for ½ horse-power engine. Exchange.—ED. FRANCIS, Bull Ring, St. Austell.

**Celestial Globe**, with brass ring and stand, globe 12in. dia., in perfect order. Offers.—W. HOGG, Oakwell-road, Castle Douglas.

"**English Mechanic**," Vols. XXXVII., XXXVIII., XL., complete, unbound; exchange 2in. stroke cylinder, or parts of Model Engine.—CHEMIST, 224, Roman-road, Bow, E.

**Hand Dynamo**, laminated armature, new, on polished baywood baseboard, complete with two 10-c.p lamps, lamp holders and wall-brackets, lights lamps well. What offers?—H. HADDOCK, Victoria-street, Radcliffe, Manchester.

Wanted, **Anvil**, about 2cwt. Will give Bench Drilling Stand and 12 drills up to 1¼in., will drill at any angle; well-made tool.—Address, 128, Barkerend-road, Bradford.

**Bichromate Battery** of 8 cells, two-quart size, very powerful. Will exchange the whole or single cells. Offers requested.—E. GOODYEAR, New-road, Spalding.

**Electro Motor**, by Cuttriss, nearly new, cost 30s. Will exchange for anything useful, watch preferred.—E. GOODYEAR, New-road, Spalding.

Quantity **Clothing**, new, men and boy's. Exchange for Photo Apparatus, Musical Instruments, Lathe, one-horse Boiler, &c.—M., 14, Church-street, Oldbury.

**Printing Outfit.** Exchange for 50 or 52in. Bicycle to the value of £2. Specimens.—WILSON, Hargate-lane, West Bromwich.

Half-horse **Horizontal Engine**, on iron bed, with governors, in splendid working order. Exchange for 18 carat gold chain, curb pattern preferred, value £4. Offers.—T. A. C., Fairfield House, Warrington.

Lot Photo. **Lantern Slide Views**, a number Scottish Scenery. Will take exchange for others or offers.—Address, FINLAY, 5, Wendover Crescent, Mount Florida, Glasgow.

A good six-keyed C **Clarionet**. Wanted, a good six-keyed E flat Piccolo, or offers.—W. HARTNUP, jun., Hurst Green, Sussex.

**Dark Slides**, double, mahogany, best make, quarter plate, half plate, and 1-1 plate. What offers?—F. MOORE, 1, Naas-road, Wood Green, N.

**Lantern Slides**, plain and coloured, photos, sets, and views, slipping slides, &c. What offers? Send for list.—F. MOORE, 1, Naas-road, Wood Green, N.

What offers in cash or otherwise for 40 **Swan Lamps**, 39ft. of 4in. Belting. 2 Brequet Transmitters, 62lb. No. 15 D.C. Wire?—H., 21, Westbourne Park-crescent, Paddington.

## THE SIXPENNY SALE COLUMN.

*Advertisements are inserted in this column at the rate of 6d. for the first 16 words, and 6d. for every succeeding 8 words.*

**Motor Castings**, materials for Electric Bells, Batteries, Galvanometers, Intensity Coils, Microphones.—KING, MENDHAM, and Co., Bristol.

**Insulated Wire Table**, showing size, weight, resistance per foot, feet per ohm, &c., price 3d.—KING, MENDHAM, and Co., Bristol.

**Standard Ohm**, in box, copper poles, guaranteed correct to ten thousandth of ohm, 21s.—KING, MENDHAM, and Co., Bristol.

**Wimshurst Influence Machine.**—Sole Manufacturers of Improved Pattern. Numerous testimonials as to thorough efficiency.—KING, MENDHAM, and Co., Bristol.

**Galvanometer Cards**, improved for tangent and ordinary combined, 2½in., 8d.; 4in., 10d.; 6in., 1s.; post free.—As above.

Write for **King, Mendham, and Co.'s** large new and reduced Price List, post free 4 stamps.

**Trouser Lengths**, 5s. each. Cheap Cloth for Ladies Dresses, Mantles, Boys' Suits.—HEWITT, 27, Winfield Mount, Leeds. Patterns free.

**Electric Depot**, 10, Deansgate, Manchester.—Electric Breast Pins, 25s. Electric Bells, 4s. Induction Coils, 8s.—MILLAR, Proprietor.

**Chemical Apparatus.** — Catalogue, 90pp., 500 illustrations, posted 2d.—W. HUME, Lothian-street, Edinburgh.

**Photographic Apparatus and Chemicals** for professionals and amateurs. See new illustrated catalogue, post free.—HUME, Lothian-street, Edinburgh.

New Illustrated Price List of **Screws, Bolts, and** Nuts for Model Work, drawn to actual size, sent on receipt of stamp.—MORRIS COHEN, 132, Kirkgate, Leeds.

**Do we get Heat from the Sun?** No! How the Body is warmed. Spontaneous Combustion accounted for. Eight reasons showing the fallacy of this popular delusion. By R. HUMPHREYS. Stamps 1½d.—11, Cambria-street, King's-road, Fulham, S.W.

**Old Scientific Instruments**, Broken Model Engines, &c. For estimate of cost for repairing, relacquering, &c., send particulars to H. P. LOVEGROVE, Optical Works, Slough, who makes this class of work a speciality.

**Vermilion**, best, 2s. 4d. lb.—PINNELL BROTHERS, 214, Whitechapel-road, London, E.

**Gas Engine Oil** (best), 2s. 6d. gallon.—PINNELL BROTHERS, 214, Whitechapel-road.

**Lathes. Lathes.** Cheap and good. Satisfaction guaranteed. List two stamps. Best make.—ROBINSON, Catherine-street, Sheffield.

**Fretwork.**—Catalogue of every requisite, with 600 illustrations, free for 6 stamps.—HARGER BROS., Settle, Yorks.

**Marvels.**—Double Opera and Field Glasses, from 5s. 6d. Lists, with engravings, free.—J. B. DANCER's Depot, 58, Hamstead-road, Handsworth, Birmingham.

Tudsbury and Sons' Improved "High-tension" **Wimshurst Machine**, with their new Compound Ebonite Plates.—Edwinstowe, Newark.

**Planing**, not exceeding 10in. by 10in. by 8in.—B. W. CLEGG, 18, Belinda-street, Hunslet, Leeds.

For **Model Work** (wheel-cutting in brass only); also Boring, Turning, and Screw-Cutting.—CLEGG, as above.

**Household Dyes**, 20 colours, cheap, cleanly, and expeditious. Sold by the manufacturer in 1d. and 6d. packets; gross, 7s. and 42s. Sample 2 or 7 stamps.—T. E. HOYLE, Blackley, Manchester.

**Model Steam Engines**, made or repaired, separate parts fitted up, boilers made to order; sets of castings of every description.—LUCAS and DAVIES, 21, Charles-street, Hatton Garden, London.

**Mesmerism.**—Complete written instructions. Success guaranteed. Fee, 2s. 6d.—PROFESSOR, 22, Clarendon-road, Anfield, Liverpool.

**Forges**, portable, quite new, circular and square, from 50s. each; bargains.—LOWE, Wallis-road, Hackney Wick.

**Patents, Designs, Trade Marks.** Notice.—JAMES STEVENSON, The People's Patent Agent, 20, High Holborn, London, W.C.

**Incandescent Lamps** (carbon), 2 to 8 candle-power, 2s. 6d. Trade supplied. Swan's 20 c.p., 4s. 6d.—PATRICK.

**Arc Lamps**, several second-hand, £2 each. Powerful Motor or Dynamo, £3; ditto, superior, £4 10s. Clearing out.

**Air Pump**, double-barrel, rack, massive brass fittings, on Spanish mahogany; cost £8; price £3 10s.—PATRICK.

**Illustrated List** of Electrical Apparatus, 2 stamps.—PATRICK and SONS, 529, King's-road, Chelsea, S.W.

**Oxygen Gas**, compressed in cylinders, handiest and safest for limelight.—CLARKSON, Compressed Gas Chemist, Bartlett's-buildings, E.C.

**Oxygen Gas**, compressed into iron bottles, liquid nitrous oxide and carbonic acid.—CLARKSON, Compressed Gas Chemist.

**Oxygen Gas**, compressed into iron bottles; prices on application.—CLARKSON, 28, Bartlett's-buildings, Holborn, E.C.

Astronomical **Telescopes** of all kinds and Apparatus or Fittings made by A. CLARKSON, 28, Bartlett's-buildings.

**Eyepieces.**—Huyghenian of any power to fit any telescope, 15s. each. Sun Diagonals, £1. Star Diagonals, 30s.

Astronomical **Telescopes**, second-hand, by best makers.—CLARKSON, 28, Bartlett's-buildings, Holborn, E.C.

**American Organ and Pedal Actions**, complete or separate. Cheapest in the trade.—TARR and Co., Argyle-street, Swansea.

**Lathe**, 5in. centre, screw-cutting, partly finished, cheap.—R. D. SMITH, Fazackerley-street, Chorley.

Engineer's **Stocks, Taps, and Dies** from ¼in. to ⅞, equal to new, cheap.—R. D. SMITH.

**Blocks and Rope**, pair of strong 4 sheave, perfect, 25s. Worth double.—R. D. SMITH.

**Blacksmith's Tools**, about 7cwt., punches, swages, sets tue iron, &c., 1½ per lb.—R. D. SMITH.

**Shafting, Pulleys, and Hangers**, several lots cheap. State wants.—R. D. SMITH.

**Lathe Heads**, 10in. centre, back-geared, 60s.; worth double.—RIGBY D. SMITH, Fazackerley, Chorley.

**Iron Planing** by steam, 30 by 10 by 10in. Speciality, gas engine valves.—PATRICK, Engineer, Chelmsford.

**Photography.** — Reliable **Sodic Sulphite** for Developing.—The anomalous results obtained with this salt arise from the presence of impurities in the commercial article. 1lb. of pure Special Sulphite, in handsome glass stoppered bottle, box included, sent, carriage free to any address in the United Kingdom, on receipt of Postal Order for 3s. 6d. Orders cannot be booked.—A. BOAKE and Co., Stratford, London, E.

**Model Engine Castings.** — Makers of Model Engines should send for a Set of HUGHES' Iron Castings. Best and softest metal. Lowest prices in the trade.

**Horizontal Engine**, 1¼in. bore, 2½in. stroke, 5s. 6d.; 1½in. bore, 2in. stroke, 5s. Working Drawings, 1s.

Double Cylinder **Horizontal Engine**, 1½in. bore, 2in. stroke, 10s. Double Cylinder Vertical, 7s. Working Drawings, 1s. 6d.

Vertical **Launch Engine**, 1in. bore, 1¼in. stroke, 3s., post free. Double cylinder, 5s. Working Drawings, 1s. 6d.

Half horse-power **Vertical or Horizontal**, 10s. Working Drawings, 2s. Three-quarter horse double-cylinder Horizontal, 17s. 6d.

Send for **Catalogue**, 2d. Six Lithographed Designs, 3d.—HUGHES, Mersey Dockyard, 17, Smith-street, Kirkdale, Liverpool.

**Hammond's Patent Mitre Frame Cramp** is the best, cheapest, and quickest Cramp for all mitre frame makers; it cramps the four mitres in one action, and so arranged that they can be nailed at the same time; price 22s.; sent on receipt of money orders payable to G. R. Hammond, Snodland, Kent. Diagram sent on application.

**Piles.**—Worst cases cured first application. "Indian Ointment," 13 stamps. "New African Tonics." Packets. 60 stamps (in proof for short time, 30.)—Thomas Palmer, St. Helen's, Auckland, Durham.

**Weather Forecasts** for July to the end of 1885, price sixpence, post free, from the author, T. J. Murday, Felton, R. S. O., Northumberland.

**Optical Glass** of finest quality, crown and flint; all sizes in stock to 14 inches diameter, discs and sheet.—Buckingham, Blenheim-grove, Peckham.

Special 2ft. 6in. **Lathe**, screw-cutting, surfacing, hollow mandrel, division plate, overhead, ornamental slide-rest, with other tools and fittings, cost £46; offered at £30.—Britannia Co.

**Whitworth Lathe**, Tonzie and Hines, and severa other second-hand Lathes. Send one stamp for list.

**Parts of Lathes**, rough or finished. Send six stamps for Catalogue of new Lathes and Parts.—Britannia Co., Colchester.

**Inventions Exhibition.**—Do not fail to see the Treadle Saw which cuts four feet of inch wood after you have taken your foot off the treadle.

**Gas Engines**, one-man and two-man, as noticed by "J. K. P." in English Mechanic. Britannia Co. are now making these engines: one-man, £15. Two-man will be announced shortly.

**Gas Engines**, work with little attention. Anyone can manage them.—Britannia Co., Engineers' Tool Makers, Colchester. Tool makers to the British Government.

**Gas Engine**, one H.-P. Otto, by Crossley's, first-rate condition.—98, King's-road, Camden-road, N.W.

**Organ Materials**, new and second-hand, for sale, cheap.—R. F., 184, Kennington-road, London, S.E.

**Important Notice.**—Messrs. FRY and CO. beg to draw the attention of their many friends, and those about to open shops of any kind and any business, to their extremely cheap, substantial, and stylish shop front, internal wall fixtures, and fittings, counters, showcases, nests of drawers, cases for models, bent glass cases, &c. Shops fitted complete from £15. Price list, plans, and estimates free. Distance no object. All communications answered.—Fry and Co., 90, Borough-road, London, S.E.

**Catapults**, free 1s. and 1s. 2d. Elastic Cord, 1d., 2d., 3d. per foot. Postage extra.—Moody Bell, Cheltenham.

Valuable **Patents** for sale. Metals and Cements.—F. W. Gerhard, Wednesfield-road, Wolverhampton.

"**Chambers's Astronomy**," quite new and clean, price 15s. Published at 28s.—W. R. Bland, Duffield, Derby.

**Hunting Knife**, never been used, leather and electro sheath, horn handle, 17s. 6d.—Grimwade, 50, Southwark-street, S.E.

**American Organ**, 2 manuals and pedals, made to order, £35.—G. Fryer, 17, Richardson-street, Swansea.

**Microscope Objectives.** ⅛th, ⅙th, ½in., 4-10th, 2-3rds, 1in., 2in., good English lenses, cheap; together or separate.—Edward Swift, 105, Myddleton-road, Hornsey, London.

**Formulas Worked Out** for winding Dynamos from 10 c.-p. to 500 c.-p., 8 stamps each.—H. Jones.

**Dynamo Castings**, Jones's patent H: 8 c.-p., 5s.; 16, 5s. 6d.; 20, 6s. 6d.; 30, 7s.; 70, 16s. a set.—H. Jones.

**Dynamos**, finished: 8 c.-p., 30s.; 16, 36s.; 20, 40s.; 30, 50s.; 70, 100s. each.—H. Jones.

**Dynamos** for house lighting.—Jones's Patent Laminated Fields and Armatures, 5, 6, and 7 lights, £6, £7, and £8 each.—H. Jones.

**Dynamo Machines Repaired.** Motors, with wire, 6s. 6d.—H. Jones, 48, High-street, Lambeth, S.E.

**Lathe**, 5in. centre, 5ft. gap bed, screw-cutting, treadle, quite new, cost £35 a week ago. On view. What offers?—W. Bundy, 62, Holborn Viaduct, London. Letters answered.

Brass **Model Engine Castings**, rough or finished, see new list (stamp).—Wood, Dalley-street, Broughton, Manchester.

**Recipes for Everybody.** Recipes for Everything. One, 7d. Three, 18d. Returned if dissatisfied.—Stanley, 119, Manchester-road, Poplar.

**Photographs** beautifully Copied, Burnished, equalling originals, 3s. dozen. Cabinets, 6s. 6d.—George Keitch, Artist, Fishponds, Bristol.

Pair Double-Barrelled **Pistols**, in case; also Saloon Pistol. Offers requested.—O., 60, Elsham-road, Kensington.

Two **Instruments** for direct sketching from nature. Invented by advertiser. Offers.—O., 60, Elsham-road, Kensington.

**Lathe**, magnificent 5in. back-geared, and slide-rest, steel collars, 4ft. planed bed, heavy flywheel and standards, double throw crank, &c., brand new; worth £20; take £12 12s. Seen after 3 p.m. on Saturday at 102, Teviot-street, St. Leonard's-road, Poplar, E.

**Electric Light Switches.**—Hedge's 10-lights, 2s. 6d.; 20, 5s.; 30, 8s. 6d. Patent Fusible Cut-outs from 3s. 6d. per doz. Lists free.—Globe Electrical Company.

**Carbon Battery Plates**, 4 square inches 1d. up to ⅜in. thick; plates 12 by 8 by 1⅛in., 2s. All sizes in stock up to 2ft. square.—Globe Electrical Company, 20, Dartmouth-street, Westminster.

**Lathe Castings, &c.**—See T. Taylor's advertisement in English Mechanic every other week. Established 1847.

**Electric Light.**—Four-cell Battery and Carbon Incandescent Lamps, free for 16s. 6d.—Bishop, 1, Kidderminster-road, Croydon.

**Electric Light.**—100 above Sets to be sold. Sent free on receipt of cash. (Send early.)

Quarter-plate Instantograph **Camera**, new, polished lock-up box, tripod, and various sundries, 45s.—Leggoe, Aylesbury.

Humber pattern **Tricycle**, nearly new, plated and enamelled, ball bearings, suspension saddle, £10 10s.—Leggoe, Aylesbury.

**Printing.**—100 Bill Heads, 1s. 3d.; 100 Business Cards, 1s. 3d. Larger quantities great reduction.—Brooks and Co., Rotherham.

Splendid ¼-plate **Camera and Tripod**, complete, suit amateur, £1.—Harry Wheatley, 17, Manchester-road, Heywood.

Powerful **Cabinet Hot Rolling Press**, £1, cost five times the amount.—Wheatley, 17, Manchester-road, Heywood.

New Silver Lever **Watch** (Benson), compensated balance, jewelled movements; cost £6; only £3 15s.—W. J. Brown, 46, Foregate-street, Worcester.

**An Interesting Study.** Reading the Hand. Written Explanations, with Chart, 7d.—H. Dyke, 21, North-street, Taunton.

100-light **Dynamo**, self-regulating alternating current, complete, with every improvement. Lamps, Cables, Switches, &c.—Warne.

Splendid **Dynamo** for Incandescent Lamps, nearly new, 50 ohms, 45 volts, a bargain. Lamps, Cable, Switches to suit.—Warne.

**A Gramme**, never been used, to be sold at low price for cash. Lamps and fittings if wanted. 5 and 10 light Machines, Castings, rough and finished. Amateur's Arc Lamps, and every appliance on hand and to order.—Warne.

**Price List**, stamp. All the above machines can be inspected at Warne's, 39, St. John-street-road, E.C.

**Moustache Raised in a few Days.** Send 14 stamps to Barclay and Ramsay, 6, Little Newtown, Waterford.

Pair of Irish's **Acoustic Telephones**, new, 25s.—F. Walker, Hambleton House, Moortown, Leeds.

"**English Mechanic**" and "Dictionary of Mechanics," Vols. XXV. to XXXV. of the former, and 48 monthly parts of the latter, 16s. and 10s.—J. Lapthorne, 122, New Church-street, Jamaica-road, Bermondsey.

**Photographs**, Scottish scenery, 7 by 4 size, 4d. each, Extraordinary value.—Address, Photo, 162, Trongate, Glasgow.

Clear **Gelatines** for tracing Magic Lantern Slides, 3¼ size, 4½d. per doz.—Address, Photo, 162, Trongate, Glasgow.

**Silver-on-Glass Mirror**, 12½ inches, and perfect flat, only £10.—Rev. S. Mills, Droylsden Rectory, Manchester.

New **Scientific Books** for sale. List free.—A. E. Wilson, Bramley, Leeds.

**Mesmerism.**—Professor Carigana's Mesmeric, De-mesmerisation, and Curative Instructions (written), 1s. 2d.—J. MacGrath, 28, Albion-street, Belfast.

**Magic Cube.**—"A marvel of ingenuity."—*Science Monthly*. Post free, 1½d.—James Cram, Euclid-crescent, Dundee.

Screw-cutting **Lathes**, 3in. and 4in. centres, at lowest prices.—A. Halls, Howard-street, Yarmouth.

**Red Snow** (Protococcus Nivalis) from Arctic regions, one slide, 6d.—Medicus, La Huerta, South Beddington, Carshalton, Surrey.

Two-horse **Boiler**, 4ft. by 2ft., good order, £3 10s. Photo, 3 stamps.—M., 14, Church-street, Oldbury.

**Electric Indicators**, Bell, &c., royal letters patent.—Halbart Works, 27, Penton-place, Pentonville-hill. Price list trade.

Electric, Pendulum, or **Drop Movements**, 24s. per doz. Handsome Circular 3in. Bell, 4½ mahogany French polished base, 5s.—Above.

**Makers of anything New** may open good business, by submitting samples, which, if selected, will be paid for, to Haydon and Co., 125, Strand, London, W.C.

**Incandescent Carbon Lamps**, low resistance, 3s. each. Fairy Lamps, 3s. 6d. Platinum Lamps, 1s. 3d., post free.—Todd, 14, Wentworth-road, Manor Park, Essex.

**Coca Leaves.**—The best, safest, and cheapest stimulant. Consignment of choice quality just received.—Marks and Co.

For the **Marvellous Benefits** to be derived from Coca, see last week's *Family Doctor* on the "Possibilities of Coca."

**Coca.**—Sample packet, with medical and scientific opinions, 13 stamps.—Marks and Co., 17, Newcastle-street, Farringdon-street, E.C.

**Galvanometers**, 2s. 6d. Ditto Delicate Astatic, 5s. Ditto, Tangents, with glass shade, 10s. Am-meters, 5s. Volt-meters, 5s.

**Wheatstone's Bridges**, 5s. Standard Ohms, 2s. 6d. Standard Daniell's Cells, in box, for exact measurements, 5s. each.—Bottone.

**Wimshurst's** 12in. **Glass Plates**, fitted with spindles ready for mounting, 6s. per pair.—Bottone, Carshalton.

**Dynamo**, hand, second-hand, £2; will light 5 candle Swan Lamps, &c.—S. Bottone, Stanley-road, Carshalton.

**Sixpenny Telegrams.**—Before entering the Telegraph service have home practice with your own instruments. 30s. set.

**Sixpenny Telegrams.**—Sounder and Key, on mahogany board, full size, 30s. set.—Sledge, Wyatt, and Co., Clapham.

**Sixpenny Telegrams.**—These instruments can be seen and tried at our office.—Sledge, Wyatt, and Co., Clapham.

**Sixpenny Telegrams.**—Every set warranted complete, and sent free on receipt of P.O. 30s.—S., W., and Co., Clapham.

**Sixpenny Telegrams.**—Sounder is Post Office Pattern and highly finished, with silk-covered coils, 30s. set.

**Sixpenny Telegrams.**—Every telegraphic clerk should possess a set for home practice.—Sledge, Wyatt, and Co., Clapham.

**Sixpenny Telegrams.**—We are making these sets expressly for Students of Telegraphy.—Sledge, Wyatt, and Co.

**Sixpenny Telegrams.**—SLEDGE, WYATT, and Co., Electrical Engineers, 95, Wirtemburg-street, Clapham, S.W.

**Sixpenny Telegrams.**—Number of vacancies will occur for Telegraphic Clerks. Practise at home. Ensure success.

**Sixpenny Telegrams.**—Sounder Set, 30s.—Sledge, Wyatt, and Co., 95, Wirtemburg-street, Clapham, S.W.

**Incandescent Lamps**, 20 candle-power. To clear stock we are offering at 2s. 6d. each, less discount.—Kinetic Engineering Co., 89, Saint Martin's-lane, W.C.

Leclanché and Bunsen **Batteries**, Jars, Porous Pots, Carbons, Zincs, Prepared Manganese, Sal Ammoniac.—Address as above.

**Insulated Wires**, all kinds. Electric Bells, Pushes, Alarms.—Kinetic Company, 89, Saint Martin's-lane, W.C.

**Secondary Batteries**, 4 by 3 by 1, best make, ebonite cells, post free, charged ready, 14s. each.—Banks, Bolton.

**Incandescent Lamps**, 2½ volt, suitable for above Battery, 3s. 6d. each.—Banks, Bolton Science Depot.

**Electric Bells**, English make, silk-covered wire Coils, Platinum Contacts, polished cases, 5s. 6d. each.—Banks.

**Telescopes**, three-draw, leather-covered bodies, very powerful, in case, complete, 6s. 6d., post free.—Banks.

**Bottle Bichromate Batteries**, sliding zincs; half pint, 3s. 6d.; pint, 6s. 6d., all sizes in stock.—Banks, Bolton.

**Photographic Lenses**, quarter-plate, 5s. 6d.; half-plate, 10s. 6d. Instantaneous Shutters, 3s. 6d. and 10s. 6d. Rack-work Pinions &c.—W. Banks, 32, Corporation-street, Bolton.

**Ebonite Telephone Cases**, Bell pattern, screw caps, 7s. 6d. pair. Reels wound, 2s. 6d. pair.—Banks, Bolton.

**Dynamo**, shunt-wound, will light six ten candle-lamps, in good order, 70s.—W. Banks, Manufacturing Electrician, Bolton.

**To Amateurs.**—Should there be a demand for a Model Traction Engine Materials they will be prepared.—A. Dorrington, West Gorton, Manchester.

The Amateur's **Gas Engine.** Complete Castings, 42s. Drawings, 5s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

Half horse-power Horizontal **Engine Castings**, ports in cylinder, 12s. 6d. Drawing, 18 stamps. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

Bench **Drilling Machine Castings**, No. 1 size, 3s. 9d. Drawing, 5 stamps. No. 2., 7s. 6d. Drawing, 13 stamps.—A. Dorrington, West Gorton, Manchester.

**Lathe Planing Attachment**, suit 5in. to 7in. Lathe. Castings, 15s. 6d. Drawing, 13 stamps.—A. Dorrington, West Gorton, Manchester.

4½in. **Fan Castings**, including drawing, 3s. 6d. Drawing separate, 4 stamps.—A. Dorrington, West Gorton, Manchester.

**Launch Engine Castings**, 2in. cylinder, 12s. 6d.; 3in., 26s.; 4in., 50s.; 5in., 70s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

Perfect Model of a Compound Condensing **Marine** Screw Engine. Castings, 10s. Drawing, 2s. 6d. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

Model **Steam Fire Engine.** Castings for making this splendid model, 15s. Working Drawing, 3s. 6d.—A. Dorrington, West Gorton, Manchester.

**Test Pump** for testing or feeding model boilers. Castings, 2s. 6d. Drawing, 6 stamps.—A. Dorrington, West Gorton, Manchester.

**Model Engine Castings**, 1½in. Horizontal, 5s.; 4½in. Vertical, 5s. 6d. 1½in. Diagonal, 6s. Drawings, 1s. each.—A. Dorrington, West Gorton, Manchester.

**Castings** of Cylinders, Governors, Wheels, Pumps, &c. List of Castings and Drawings, 1 stamp.—A. Dorrington, West Gorton, Manchester.

**Universal Trade** and Amateur Supply.—Lecture requisites; light, heat, air, water, geology, engineering, chemistry, photography, &c. Wholesale and export.—Caplatzi.

Frictional and **Induction Machines**, Plates, Cylinders, Stands, Conductors. Glass, Vulcanite. Hundreds of Lecture Accessories. Their parts.

**Coils** to 8in. spark. Experimental, Resistance, Medical, Dynamo, Bell, Telegraph, Galvanometer, and other purposes, Vacuum Tubes. Matchless cheapness.

**Batteries.**—Thousands lighting, experimenting, medical, depositing. The Universal Four-cell Case, 15s. Convenient, durable, and economical.

**Lamps, Arc**, 10s., 200s. Incandescents, Platinum, 1s. Carbons, 2s. 6d. Various makes. Holders, Switches, Leads, Meters, &c.

**Lecture Lanterns** with Microscopes, Polariscopes, Kaleidoscopes, Troughs, Condensing Lenses, Scientific Slides, Objects, Parts, Fittings, Accessories; various.

**Boats.**—17ft., with half-horse Engine, complete, £21; 8ft. Scale Model, £10; 2ft. Locomotive, £8; rare bargains.

**Acoustics.**—Sonometers, Sirens, Savard Wheels, Chadni Plates, Organ Pipes, Tuning Forks, Bows, Resonators, Reflectors, Bellows, Flames, Waves.

**Heat.**—Hundred Experiments. Tyndall, Wheatstone, Trevelyan, Marcer, Rumford, Leslie Gronisand, Jugenhause, Thermometers, Pyrometers, Thermopiles, Reflectors.

**Pumps.**—Air, Steam, Mercury, Hydraulic, Lift, Exhaust, Condensing, Boiler Testing, Feeding, Sub-cutaneous, Electric, Microscopic, Filter.

**Light Experiments**, half, whole, and Cylindrical Lenses, Polarising, Crystals, Gauges, Spars, Rhombs, Nicols, Tourmalines, Micrometers, and Diffraction and Wave Plates.

**Astro. Telescopes.** Cheapest house. O.G.'s, Eyepieces, Finders, Stands. 2¾ Transit, by Cary, 80s. Smaller, various. 4in. Wray.

**Photography.**—Cameras, Ross, Dallmeyer, and foreign Lenses; quantity of Double Backs, Bodies, Stands, Screws, Sensitised Papers, Silver, Gold Solutions.

**Engines**, Boilers, Parts, Fittings. Numberless second-hand; far out cheapest in the market. See new list.

**Chemistry.**—Apparatus, Chemicals, Balances, Stills, Furnaces, Blowpipes, Chemical Cabinets, Rare Metals, Minerals Models of Crystals.—Caplatzi.

**Text-Books of Science**, Astro. Periodicals, English Mechanic, "Design and Work," the "Engineer," "Science Review," many years; cheap.

Catalogue, 2d. **Caplatzi**, Science Depot, Hire and Exchange, Chenies-street, Tottenham Court-road, near British Museum.

## THE SOARING BIRD: A MECHANICAL PROBLEM.

THE problem of the soaring bird is one that has exercised some of the 'cutest intellects, and our own columns contain many contributions on the subject. Perhaps it is for that reason that Mr. I. Lancaster, of Chicago, has sent us his tractate, in which he attempts to solve the problem, "How does a soaring bird manage to sustain itself in the air on motionless wings?" It must be confessed that he has made a very good shot. He starts with the assumption—perhaps we should say proposition—that a body can do work by falling without losing its energy of position, and to reconcile that "seeming impossibility" with the laws of mechanics, he has written his tractate, in which, however, he offers no "experimental proof," as that would carry the question further than he is at present prepared to go. He contends, nevertheless, that if the Newtonian laws of motion are to be depended on, and there is no flaw in the mathematical treatment of the abstract forces, as used by writers on mechanical science, then the possibility of a device enabling gravity to become a continuous motive power is established. The soaring or hovering bird is an example of an imperfect character; but a rightly constructed plane surface is a perfect example, because such a surface can be so placed at an incline to the direction in which it meets the air that its gravitating force will do more work on the atmosphere than the rear-push can do. The total work done by both forces flows to the rear in the disturbed air, and there falls to the tension of the surrounding atmosphere; but a part of this otherwise wasted force is utilised, and takes the place of the rear-push, when the gravitating force will be the only one actuating the plane. The question then arises, Can a surface be constructed in which gravity will do more work on the air than is done by the rear-push? If that question is answered in the affirmative, it makes artificial control of the atmospheric spaces possible; in other words, it solves the problem of flight. Innumerable observers have testified to the fact that birds soar; that is, they rise and fall in the air without perceptible motion of the wings, and that is a mechanical problem which awaits solution. How is it done? Flight by motion of the wings can be understood; but how do birds support themselves in the air, with their wings outstretched it is true, but so far as we can see perfectly motionless. The carrion-eating vultures are a good example. They float for hours in the wind with extended wings, and without more than a suspected alteration of the inclination of the wings as regards the direction of the wind, they rise or fall steadily, and float with apparent ease, now at one height, now at another. We say a "suspected alteration," because from what we know of the mechanism of bird-soaring it is reasonable to suppose that there must be some alteration in the inclination of the wing surface; but so far as can be observed, the wings are perfectly quiescent. Mr. Lancaster offers the following explanation:—The bird weighs 8lb., say, and the wind is travelling at the rate of 20 miles an hour, or about 30ft. in a second; by an alteration in the inclination of the lower surface of the wings, the direction of the wind is changed from the horizontal to the vertical, and we have then a weight of 8lb., which should fall at the rate of 30ft. per second; but it does not, and we have 240 foot-pounds as the motive power. That raises the bird of 8lb. 10ft. per second against gravity, which absorbs 80 foot-pounds, and we have 160 foot-pounds left to hold the bird against the wind and to compensate for losses, which are the equivalent of friction in a machine. Mr. Lancaster supports this conclusion by arguments that certainly help to establish his position, which show that after making due allowance for friction and waste in lateral motion, there is still ample energy in the rear. He has consulted the tables of Smeaton and Hutton, showing the action of air on inclined planes, and refers particularly to the experiments made by the Aëronautical Society of Great Britain. In the latter, the results of which are confirmed by his experiments, it was found that where the angle was very oblique, the ratio of the perpendicular to the direct force increases faster than the angle diminishes, which serves to show that there is some uuexplained action of the wind, or of atmospheric air, which acts on planes with greater force at right angles to the direct than could be assumed to be the case with an abstract force estimated from a diagram in which the resolution of forces is plotted down.

Drawing two lines at right angles, the horizontal one representing the direction of the wind, the vertical the position of the plane, we have a quadrant in which the plane can be placed at various angles between 0° and 90°, and as the angle decreased, or the inclination of the plane varied, a less and less body of air would strike the surface; but as the weight to be supported remains the same, the velocity of the wind would have to be increased just as the quantity diminished. Hence, the rear support would remain precisely the same in each case—viz., just enough to hold the plane against a wind strong enough to support, say 10lb. If the air is supposed to be calm, and the plane is moved upon it, the same result comes out theoretically. Where the angle is 45°, or an inclination which would resolve the abstract force into 1 direct to 1 of perpendicular, the movement would be slow, but the push considerable. With an inclination of 1 to 5, the push would be only one-fifth as great, but five times faster, and the rule holds good with any angle; but the question here is, does the element of elasticity give to a flow of air powers different to those found in the case of a flow of water? Mr. Lancaster has satisfied himself that the mathematics of the matter go to destruction in the solvent of common sense, and in his attempt to produce harmony arrives at the conclusion that the usual methods of determining momentum must be modified to meet the peculiarities of the case. He finds in the statements of Clerk-Maxwell a key to the mystery, for that writer in "Matter and Motion" says: "It is true that when we say that a body is at rest we use a form of words which appears to assert something about that body considered in itself, and we might imagine that the velocity of another body, if reckoned with respect to a body at rest, would be its true and only absolute velocity. But the phrase 'at rest' means in ordinary language 'having no velocity with respect to that on which the body stands,' as, for instance, the surface of the earth or the deck of a ship. It cannot be made to mean more than this. It is, therefore, unscientific to distinguish between rest and motion as between two different states of a body in itself, since it is impossible to speak of a body being at rest or in motion except with reference expressed or implied to some other body." Mr. Lancaster also quotes from the well-known article Aëro-dynamics, in the old "Penny Cyclopædia," and suggests the following case as an example: Suppose a flat body weighing 10lb. to be placed high in the air in a horizontal position, the atmosphere being still and homogeneous throughout, and the body allowed to fall. At first it will be variable in its motion, until a velocity is reached at which its descent will be uniform, the change being caused by the disturbances produced in the air by the falling body exactly balancing the momentum of the body at the velocity at which its motion became uniform. Suppose, for instance, that velocity to be 10ft. per second, then the tensions set up in the atmosphere will be equal to 10lb. moving ten feet in one second, and they will constitute the reactive forces against the active forces of the falling body, and we have a case of a falling body doing work. On the other hand, if the body, uniformly moving, be arrested and held in place, and the air be supposed to move vertically upwards with a velocity of ten feet per second against it, the body would, if released, be at rest relatively to the earth, and would be supported on the moving air. Mr. Lancaster holds that the two cases are identical: the forces are the same, the processes and the effects are the same, the factors are alike, and the sum total is the same. So if a properly-constructed device meets the air in a horizontal instead of a vertical direction, with the same effect of reaction against gravity, the latter will become a continuous motive power operating the device indefinitely and doing work on the atmosphere sufficient to balance the gravitating force. It would seem that we have in these considerations an explanation of the soaring or hovering bird, which, as has been pointed out before, may be assumed to be continually sliding down an upward current of air, the air itself carrying it upwards as fast as it slides down, and thus producing a condition of absolute rest, so far as the observer on the earth is concerned. Darwin was one of the first to draw attention to the fact that birds can and do remain perfectly motionless, so far as the eye can detect, and Mr. Lancaster corroborates him. He observed off the south-west coast of Florida a number of pelicans which rose into the air, and facing the wind floated for several hours in his vicinity, passing many times over his head as they oscillated up and down the beach, on which he had erected his apparatus for determining any deflection from the horizontal in the flow of the air. That consisted of a radial arm balanced at the joint, and feathered with five square feet of surface horizontally, its outer end moving through a circle of twelve feet radius. An ounce weight would throw this arm through 30° of arc either up or down; but the indicator remained level during the whole time the performances of the birds were watched, and Mr. Lancaster says he has never detected any deflection from the horizontal in a coast wind twenty feet from the ground, or above tree tops. The entire movement of air is on level lines, and all hypotheses of upward flowing currents of air to sustain the bird may be abandoned, as they do not exist, while a dead calm is the very best state of the atmosphere for a soaring bird. The conclusion is, then, that the direction of the wind is changed by the inclination of the wings, and that the mere weight of the bird tending to fall through still air produces by the angle of the wings sufficient elevating or sustaining force to enable the bird to float without movement of its wings. Soaring pelicans are rather exceptional, and one Mr. Lancaster shot was found to weigh twenty-five pounds (twelve pounds being foreign matter, mainly fish in its gullet), to measure 9ft. from tip to tip of the wings, which presented about as many square feet of surface to the air. There is no publisher's address to the tractate we have thus noticed; but as the matter in-

VOL. XLI.—NO. 1,064.

terests many, we may say that Mr. Lancaster's address is 335, Wabash-avenue, Chicago, U.S.A., and that the work contains several diagrams which help to elucidate the subject.

# THE INTERNATIONAL INVENTIONS EXHIBITION.—XV.

## Paper, Printing, Bookbinding, Stationery, &c.

ALTHOUGH the group which bears this title (26) is, from the public point of view, one of the most attractive, it must be confessed that it is rather "mixed," while no one of the trades can be said to be adequately represented. So far as paper is concerned, beyond samples of wood pulp and a rag engine or two, the manufacture of that invaluable article is not illustrated at all. The most interesting exhibits in connection with it are the samples showing the stages through which wood passes in becoming a pulp suitable for the papermaker. It is about 25 years ago since Voelter succeeded in perfecting a process of disintegrating wood, by grinding it in the green state with abundance of water; but recently great improvements have been introduced, and now wood pulp enters largely into the manufacture of the cheaper and coarser kinds of paper. Mechanical means have been supplemented or superseded by chemical methods, and by removing the lignine which binds the individual cells together the cellulose is obtained in an isolated form, and is nearly as good as the product obtained from esparto fibre, while it lends itself readily to the bleaching processes. The cellulose thus obtained is perhaps less suitable for papermaking than for other purposes, as it becomes more brittle and less tough; but the exhibits of samples of the cellulose and of paper made from it, with the addition of more or less rag pulp or other binding material, show conclusively to what a high degree of perfection the manufacture has attained in a quarter of a century. So far as printing is concerned, it is principally in connection with the machines for working off impressions from the type formes that the group can be said to be an exhibit of printing processes, and even in that case it is only certain special machines that are to be seen. It would have been highly interesting, for instance, to have had the machine at work which, according to the preface written by Dr. Hugo Müller, F.R.S., was made in 1859, for the *Standard*, and was capable of producing 20,000 copies per hour! It would also have been more interesting to have had at least one of those type-setting machines which have been "simplified and perfected," for so far as we have been able to discover only one of them has been placed in the East Gallery for public inspection and criticism. Entering this gallery by the south door we find an interesting and attractive exhibit by the proprietors of the *Graphic*. Around the walls are a number of pictures; but surrounding the machine, which is exhibited at work printing coloured plates for their paper, is a table on which are displayed the various processes of producing illustrations. The effect produced by ten workings of different colours is shown by means of a proof from each plate side by side with one exhibiting the state of the picture after each impression. Mr. E. Badoureau contributes cases of wood-engraving tools, a log of boxwood, pieces of the same cut up, and various sized woodblocks for the *Graphic*, showing the manner of piecing together (in two styles) to make up the large blocks required by our contemporary. Then there is a photograph on wood, an artist's drawing on wood, and a finished block, while alongside is a mould in wax, an electrotype shell, and a mounted electrotype. Altogether the *Graphic* exhibit is one of the most interesting in the whole group so far as the public are concerned. Mr. W. J. Ingram (*The Illustrated London News*) is entered in the second edition of the catalogue as exhibiting a four-colour rotary machine; but the exhibit is really a two-feeder Bremner machine at work printing portions of the forthcoming issues of the paper. It is probably as good a machine of the type for printing "cuts" as can be found, for the cylinder reverses its action with the movements of the table, and the arrangements for obtaining impression and for distributing the ink are practically perfect. Mr. F. R. Daldy, City-road, E.C., shows Smyth's thread sewing machine, and the same inventor's machine for sawing the grooves in the backs of books into which the tapes or cords enter. The sewing machine is said to be capable of working at the rate of 18,000 sheets per day. Bookbinders and others interested should compare this machine with those shown by A. Brehmer, of Moor-lane, E.C., at whose stand a wire staple machine is exhibited, though not at work. In these machines short bits of wire are driven through the backs of the sheets, and the ends are bent over. The method has been adopted by some publishers for binding their books, and it has the merit that there is no likelihood of the wire staple coming out. At Stand 1976 Messrs. Virtue and Co. exhibit the process of printing from copper plates, in the shape of etchings for the *Art Journal*. In this case the copper-plate is faced with iron by the aciertype process, to give greater durability, for in this method of printing great pressure is required. The engraved portions of the plate are smeared over with a thick ink, which is well worked into the etched lines, and every portion of it except that retained by the lines is carefully removed by sundry manipulations, the final operation leaving the plate with a highly-polished, almost chemically clean, surface. The plate with a sheet of paper over it is then drawn through the press, which consists of a couple of cylinders, and the paper being thus forced into contact with the ink, pulls the latter out of the lines in which it has been buried. The process is necessarily a slow one, about 80 prints being a good day's work. Henderson, Rait, and Spalding, of Marylebone-lane, have an interesting historical exhibit in the shape of the methods adopted for printing music, including the punches, matrices, and rules used in the Scheurman process, and the blocks and rules of the Cowper process, in which the notes were printed from raised types on ruled paper. They also show the modern method, in which the music is punched into a pewter plate, and an impression is taken and transferred to stone, the printing being accomplished by the ordinary lithographic process. It is impossible in the space at our disposal to notice the various printing machines, both letterpress and lithographic, and it would be useless to attempt to point out their chief features and differences without illustrations; but printers will certainly be interested in the self-delivering, self-registering, gripper platen machine of Mr. A. Godfrey, North Reddish, No. 1981. In this machine the platen and the forme or type surface are both perpendicular to the base of the machine throughout the movement, the platen sliding backwards and forwards in horizontal guides. The ink-table is semicircular, with a run of 32in., and a rocking "doctor" delivers the ink at the fore edge just as the distributing and inking rollers come up from the face of the forme, whence they run over the table, underneath, and pass between the forme and the platen as soon as the latter has receded far enough. No skill is needed in feeding, as the sheets are laid on a fixed sloping board, are adjusted by automatic lays, and seized by grippers which take them underneath and bring them up in front of the advancing platen, the gripper frame revolving around the frame carrying the platen by a quarter rotation at each impression. The printed sheet is taken from the grippers by one of the now well-known self-delivering arrangements. The speed is 2,500 per hour, or about three times that of the ordinary platen machine. Slurring is impossible, and the type is not injured even when only a few letters are required to be printed in the corner of a sheet. Messrs. Greenwood and Batley, Leeds, exhibit their patent continuous web platen machine, in which the paper passes from the roll, up between the platen and the forme, where it is momentarily stopped for the impression to be made. These machines will commend themselves to jobbing printers, and are not without interest to the mechanic. Mr. W. C. Horne, of Aldermanbury Postern, shows a patent duplex folding machine at work on a sixteen page paper. The sheet is laid on the table and is drawn by grippers under the falling knife blade, which takes it through the slit in the table, when it is again folded by another blade at right angles to the first, which carries the sheet to the final folder, when it is passed out to a shoot which tips it over to the heap. At the adjoining stand, Mr. J. J. Ayling, of Crane-court, exhibits the process of zincography from the photographic negative to the finished block. The drawing is transferred by photographic or other means to the zinc plate, the lines being in a bituminous ink, which is not attacked by the acid. The plate is then immersed in an acid bath, and as soon as a portion of the unprotected surface is eaten away it is again "inked up" or treated with a composition which prevents the acid from eating underneath the lines of the drawing. Plates are shown in ten different stages, exhibiting the effects of the acid at each step. Waterlow and Sons, at stand 2026 also exhibit blocks for printing purposes produced by various processes, and have several Woodbury-type printing presses at work. They also show in action a railway ticket printing machine, which numbers the tickets consecutively at one or both ends, and turns them out at the rate of 10,000 an hour. A machine for counting the tickets is at work as well, and forms the complement to the printing machine. Connected with printing, and especially important to those requiring rapid production, are ink rollers, for the speed of the modern machines is practically limited by the capability of the rollers to withstand the work they are called upon to do. The Durable Printers' Roller Co., of Shoe-lane, exhibit a collection of their exhibits, and a roller which has been at work for six months. The composition, though nearly as soft as the ordinary glue-and-treacle mixture, is very tough, as is that also shown by the Messrs. Harrild, of Farringdon-street, E.C., who have a fine exhibit of Bremner machines—fine-art, letterpress, and chromo-litho. Messrs. Richardson, Koolman, and Isger, of St. Bride-street, E.C., show what can be done with the electrotyping process nowadays, for they exhibit their fine-art moulding composition, an electro of a well-known picture issued by the *Graphic*, which contains 1,000 square inches without a join, curved electros for rotary machines, and Lanham's patent lace-printing electros, in which the mould being taken from the article, the printed representation must be exact. This method is also applied to leather and other articles in the production of rollers to impart the "grain" to artificial manufactures. Mr. Alexander Fraser (Neill and Co., Edinburgh) exhibits his type composing and distributing machine, and, singularly enough, books printed by its aid, as if the type had a different appearance when "set up" by machine. The apparatus resembles to a certain extent Kastenbein's, in which the types slide down grooves all leading to a common point of emergence; but in the Fraser machine the types are arranged in grooves at the top, and are pushed forward by metal fingers actuated by cords attached to the selecting apparatus. The keyboard consists of a number of plungers marked on the top with the letter or sign carried by the type controlled by the plunger, and the method of operating is to strike a rather smart blow with the middle finger of the right hand on the plungers, while another plunger is depressed by the left hand. The distributing machine has also a keyboard with plungers, and a plate containing a number of grooves down which the types slide; but as it is necessary for the operator to read the type and then touch the required plungers, it is doubtful whether there is much economy even in operating the machine. As is well known, however, there are several reasons why type-composing machines have never made much progress, the most important of which are that when the cost of the machine is taken into consideration and the expense of the repairs, together with the wear and tear of type sliding in brass grooves, the "economy" gradually becomes smaller by large degrees. Then, as a climax, for newspaper work, at all events, the operator must be fairly intelligent, capable of reading manuscript, and of equable temper, for at times the machines are very trying. It may be that Mr. Fraser's invention avoids all the well-known disadvantages; but, from what we have seen of its performances, we are not inclined to think that at last machines will be as numerous in the composing-room as cases. From type-composing machines it is an easy step to type-casting machines, and at the stand of Mr. O. Titchener (2,033), of Wilmington-street, E.C., we can see the latest improvements. The matrix and the mould are carried in a swing frame, which, when at work, abuts against the nozzle of the melting pot. A plunger in the latter forces the metal into the mould and an automatic arrangement knocks off the break or tail (a superfluous piece of metal at the bottom of the type) and ejects that on one side, while the types themselves are sent into a shoot on the other. The types thus cast have perfectly square edges, and only require setting up on their faces and their lower ends levelled to finish them. Two processes in the old style are thus avoided, viz., the removal of the break by hand and rubbing to take off burrs or rough edges. Titchener's patent delivery apparatus frees the matrix (the part containing the punched letter) from the mould (the part which forms the sides and body of the type) horizontally, instead of at an angle, thus preventing the tearing up of the face. The "small work" machines cast all sizes generally used in book and newspaper work, and if steam power is used one machine casts at the rate of from 3,000 to 4,000 per hour. Type-writers are exhibited in several forms, and there are sundry processes of the Trypograph pattern for multiplying copies of letters; while in the exhibits, which we suppose are classed under the head of stationery, there is quite a miscellaneous collection, from an improved envelope and a postage-stamp affixer to an adjustable portable tent! Visitors, however, will be interested in the paper-hanging printing machine exhibited at work by Osborn and Shearman, of King's-road, S.W., while many will be attracted by the ingenious envelope-folding machine of Mr. W. H. Hook, East Dulwich, S.E., which has movable boxes for adapting the machine to various sizes and shapes, and is capable of working up to 3,000 an hour. The apparatus employed in making rubber stamps—that is, the presses—are shown by one or two exhibitors, and there are some recent "improvements" in pens, penholders, drawing-boards, artists' brushes, and easels; but they help rather to fill up space than to add to the importance of the exhibition.

## ELECTRICAL INSTRUMENT MAKING FOR AMATEURS.—I.*

By S. R. Bottone.

THE amateur, especially if he be young, inexperienced, and unblest with "filthy lucre," must ever command our sympathy and respect. He, without any hope of reward, except that gratification which follows the acquirement of knowledge, works on, under the greatest difficulties, to the attainment of his end—an end which, in nine cases out of ten, tends directly to the benefit of his fellow-creatures.

Nearly all the really useful inventions and discoveries, which have rendered the 19th century so remarkable as a season of progress, must be attributed to amateurs. For this reason, if for no other, we should render every assistance in our power to the *bonâ-fide* amateur, and for this reason, along with another, have I attempted, in the following pages, to guide the tyro in his attempts at the construction of the more useful pieces of electrical apparatus. The other reason is that "a fellow-feeling makes us wondrous kind," and as I myself have felt acutely the need of assistance at the beginning of my amateur-scientific career, so I am pleased to suggest when and how much trouble may be saved, and expense spared by the adoption of certain simple modes of procedure.

§ 1. *Tools.*—The true amateur, as a rule, has not a large assortment of tools. Little by little he gets together, or constructs, those which are absolutely necessary for his purpose; but he seldom aspires to the complete paraphernalia of a workshop. Still, there are certain tools that are indispensable, of which the following is a list in order of utility:—

1 Large pocket-knife.
1 Fine penknife.
1 Archimedean drill and bits.
Pair of cutting pliers.
Pair of large scissors for metal.
Pair of small scissors.
Several files, large and small.
1 Hammer.
1 Mallet.
Bradawl, gimlet, pincers.
Small bench vice.
Small tenon saw.
Soldering iron.
Spirit lamp.
1 Wheel glass cutter or diamond.
Pair of compasses.
2ft. rule.

I should like to have put a lathe at the head of this list, for that is really the king of tools; but I would not deter the student from making electrical apparatus because he has not a lathe, as most may be made well without one, though better with.

Besides tools, the materials mentioned below will be found useful. They need not be procured all at once, but as occasion demands. If the amateur adopts the plan of keeping up a little stock of his materials and tools, as they are worn out or consumed, and more especially if he remembers that, "Order is Nature's first law," and that there should be "a place for everything, and everything in its place," he will turn out better work, keep his temper, and work better than if he allows himself to degenerate into a slip-shod style of doing things. Let him never say "that'll do" to anything capable of improvement.

§ 2. *Materials.*—The following will be found useful in carrying out the instructions given in the ensuing pages:—

Glass rods from ⅛ to ½in. in diameter.
Ebonite rods from ⅛ to ½in. in diameter.
Glass tubes from ⅛ to ½in. in diameter.
Guttapercha.
Glass bottles, preferably green glass.
Sheets of glass; every piece is useful.
Bottoms of broken wine-glasses as stands, &c.
Tinfoil.
Sheet zinc and sheets of tinned iron.*
Sheet copper.
Sheet brass, and brass rod, ⅛in. diameter.
Solder.
Chloride of zinc.
Rosin.
Needles.
Watch springs.
White hard varnish.
Red lead.
Benzoline.
Burnt umber.
Copper wire of various sizes.†
Prout's elastic glue.
Methylated spirits of wine.

Having these materials at hand, the amateur will find that several operations are required so frequently as to render a certain amount of technical skill absolutely necessary if the work is to look neat and act satisfactorily. Among the first of the amateur's requirements must be placed the power of soldering.

§ 3. *Soldering.*—For small work, an iron, shaped as shown at Fig. 1, will be found extremely useful. The amateur can easily construct this for himself by boring a $\frac{3}{16}$ hole in a copper wedge 2in. long by ½in. thick, and ½in. wide on the base. An iron rod, 15in. long, is straightened out for the handle, and the end of this rod is heated in the fire and hammered up until it can be thrust through the hole in the upper rod; what projects is then hammered down so as to form a kind of boss or rivet head, to prevent the copper bit from moving. The other end of the rod may then be filed or hammered to a point, and driven into a wooden handle. Five inches of broom-handle will answer the purpose, if nothing better can be got at.

FIG. 1.

In order to solder successfully, four things are essential. Firstly, the portions to be soldered must be made scrupulously clean, either by scraping with a piece of sharp knife blade (kept specially for this purpose), or by sandpapering, or by filing, whichever is most convenient. Secondly, the portions to be soldered must be raised nearly to the temperature of the melted solder. For this reason the amateur would surely fail were he to attempt to make a good joint, say, between two sad irons with an ordinary soldering bit, unless he previously heated the irons to nearly the melting point of solder. In ordinary small work, where wires are soldered to wires, sheets to sheets, &c., the heat of the soldering-iron itself is generally sufficient, not only to melt the solder, but also to raise the temperature of the surrounding portions to be joined to the requisite point. Thirdly, the nose of the soldering iron must be perfectly clean, and covered with melted solder, or, as it is technically called "tinned."

To insure this result the soldering iron must be placed in a clear red fire until nearly red-hot (if allowed to get too hot it will not take up the solder at all), then quickly and lightly filed on one face, and *at once* plunged into a rod of soft solder, on which a little powdered rosin has been placed. The heat of the soldering iron will cause the solder to melt, and run into globules. If one of these be allowed to run into the lid of a milk-tin, or other convenient tinned iron receptacle in which a little powdered rosin is also placed, and the *filed* face of the soldering iron rubbed briskly over the melted solder, the surface of the copper bit will be found to have taken a coating of solder as brilliant as a looking-glass. Should this not be the case, the iron must again be heated and filed and rubbed over the solder until a perfect coating has been obtained.

When once the nose of the copper-bit is well "tinned," it is sufficient after each heating (provided it has not been overheated so as to burn off the solder) to rub the iron iron briskly on a piece of old carpet, kept especially for this purpose, just before touching the solder. Fourthly, the surfaces to be united must be kept perfectly clean and unoxidised during the application of the heat necessary for soldering by the application of some substance which prevents the access of air, &c., to the heated surfaces.

These substances are various, and some are more adapted to one metal than to another. Thus rosin is excellent for tinned iron and for copper. Hydrochloric acid (spirits of salt) is perhaps the best for zinc. Chloride of zinc (killed spirits of salt), again, is excellent for iron, for copper, and for brass, where the surfaces can afterwards be well washed.

A lump of sal-ammoniac (chloride of ammonia) is also very useful for removing the oxidation from the copper bit by rubbing it against the lump for a few seconds, after heating.

§ 4. As an example of the mode of proceeding, let us suppose we wish to solder a wire to the copper plate of a Daniell battery. We begin by cleaning the copper plate at the spot to which we wish to attach the wire by rubbing it with a piece of glass or sand paper until the surface is as brilliant as a mirror. In like manner we polish and clean the end of the copper wire. Laying the copper plate flat on the board which we keep expressly for soldering on, we place the copper wire on the desired spot.

We now put the soldering iron in the fire* (it having been previously tinned, as above described), and watch it until it shows by the melting of the solder on the surface that it is hot enough. We then remove it from the fire, give a rub on the sal-ammoniac or piece of carpet, then take up a globule of solder by touching one with the cleaned nose of the bit, and, lastly, having quickly touched the surfaces both of the copper plate and wire with a feather dipped into the chloride of zinc solution, rub the surface of the plate and wire simultaneously with the soldering iron. As soon as the surfaces become sufficiently heated, the solder will be seen to flow over them. The wire must then be pressed into its desired place, the melted solder rubbed well over the point of junction, the iron removed, while the wire is held motionless in its position until a sudden dulling of the surface of the solder shows that it has set and is solid enough to hold the parts together. After soldering with chloride of zinc ("killed spirits," "soldering fluid"), always wash in plenty of water, to prevent rusting.

(*To be continued.*)

## COX-WALKER'S ELECTRIC TELL-TALE, &c.

AT their stand in the Inventions Exhibition, No. 1362, amongst other exhibits, Messrs. Harrison, Cox-Walker, and Co., of Darlington, have an electric tell-tale, a smaller fac-simile of which has been well tested for about three years in the East Riding Asylum, York, and has been recommended in one of the "blue books" of the Commissioners in Lunacy—a recommendation which led to its adoption in several other institutions of a similar character. The instrument shown at the Exhibition is for 30 stations, and consists of a clock driving a long cylinder around which the prepared record paper is fixed. On each side of this cylinder and slightly above it are electro-magnets, the armatures of which carry little brushes with reservoirs of ink. The frames carrying the magnets swing into position over the cylinder, and are separated when it is desired to read the record or remove it. Each magnet communicates with a circuit-maker placed in some part of the building or works, and the watchman is provided with a key which he inserts into the circuit-maker and turns. A current is thus sent to the corresponding magnet, which attracts its armature, and the pencil attached to that makes a mark on the paper cylinder, which is so ruled that the exact time can be read when a given station was visited, when it was left, and the time occupied in going to the next station. The tell-tale itself is kept in a glass case, and is placed where it cannot be tampered with, while the sheets of paper as they are daily removed can be dated and filed for reference if necessary in the future. Watchmen and others whose duty it may be to make the records have an advantage in connection with this electric tell-tale that they are not obliged to be at any given station at a fixed time to record their presence. They can make the circuit at any of the stations, and the time and place are accurately indicated. Another useful appliance is a double electric semaphore for pit shafts, hoists, or other places where it is important that a definite and indisputable signal shall be given from two stations before the machinery is put into motion. This semaphore has two arms, one being worked from one station, and the other from a different station ; but the bell will ring only when both arms have been thrown up. Both arms fall automatically when the engine or cage starts. The mining and railway-signal bells for long distances exhibited deserve attention. One with a dome 12in. in diameter is fitted with a relay, and the bell magnet is actuated by a local battery brought into action by the relay. The extra-current spark is taken by a light contact spring, so that the platinum contact is preserved ; and the tapper is fitted with a spring which slides over the contact-piece, and by the slight friction at each tap effectually cleans the parts.

---

* All rights reserved.

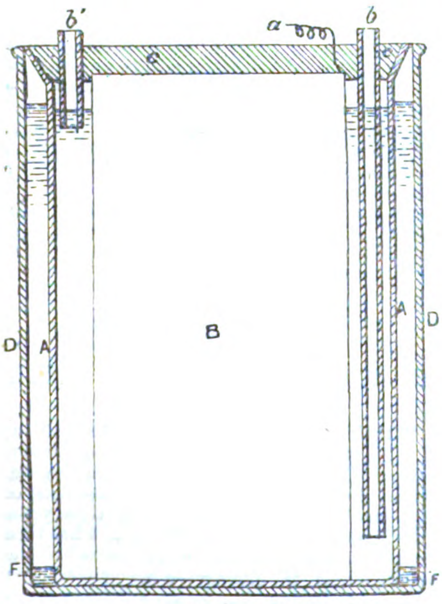
* Clean beef tins, sardine tins, &c., may be worked up very well and economically.

† This had better be procured as required.

* Care must be taken that the fire is emitting no sulphurous smoke, otherwise the iron will surely *not* take up the solder.

## SKRIVANOW'S IMPROVED VOLTAIC CELL.

AN improvement on the Skrivanow cell has been recently patented in this country by Mr. P. G. Skrivanow, of Paris, whose aim has been to devise a cell which will give a powerful current, and yet occupy only a small space. His improved battery is of the class in which two liquids are employed, and is constructed to present a multiplicity and large area of acting surfaces without a corresponding increase of bulk. The battery cell, shown in vertical section in the figure, is provided with flat or narrow vessels, or cells, A of porous material, the walls of the vessels being made as thin as possible, and as near to each other as is practicable to leave sufficient space for the liquid, and thin plates B of platinum or carbon, forming electrodes, are placed one in each of these vessels A, and are connected with the external circuit by wires *a*. The upper parts of the porous vessels are sealed preferably with paraffin wax at *c*, and two tubes *b* $b^1$ (which may be of glass) are passed through this sealing, the tube *b* descending to within a short distance from the bottom of the vessel, and being employed for introducing the liquid into the vessel. The tube $b^1$ is shorter, and is provided for the escape of air and gases from the interior of the vessel. The elements thus constituted occupy very little space laterally, and are arranged side by side as closely as possible in a trough or vessel D, constructed of gutta-percha, ebonite, porcelain, wood, or other suitable material. The other elements are formed of thin plates of zinc E, placed in the trough D, being arranged alternately with the porous vessels A, and elements B. The said plates of zinc can be most conveniently connected together electrically at their lower edges by being placed in contact with mercury F, contained in the bottom of the trough or vessel D, or by any other equivalent connection. This mercury or contact is also connected to the negative pole by a plate *d*, preferably of platinum soldered to a wire *e*, leading to the external circuit. Nitric acid is introduced through the tubes *b* into the porous vessels A, and sulphate of zinc (preferably as pure as possible) is placed in the trough or vessel D. The arrangement as described presents a large surface of the electrodes or plates to the action of the liquids or electrolytes, and the porous vessels A being made as flat or narrow and thin as possible, enable a large number of plates or electrodes to be packed or contained in a small compass.



## LIPPMANN'S APPARATUS FOR ELECTRIC MEASUREMENTS.

THE following description of Lippmann's apparatus for electrical measurements is given by M. Hospitalier in *La Nature* :—

Measurements of the intensity of electric currents is daily becoming an affair of more and more importance. Although there exists a large number of apparatus designed for this purpose, very few of them present all the qualities that are required for their practical employment. Most of these apparatus are based upon purely galvanometric actions. The type of the genus is the well-known apparatus of Marcel Deprez, in which a soft iron needle is placed in the intense magnetic field formed by the two branches of a U-shaped magnet. The current to be measured traverses a bobbin and develops a magnetic field whose lines of force are directed at right angles with those of the magnet. Under the action of these two fields the needle assumes an intermediate position that depends upon the intensity of the magnet's magnetisation and the form of its polar pieces, upon the form and dimensions of the needle, upon the form, dimensions, and number of coils of the bobbins, and upon the intensity of the current. There is, then, *à priori*, no simple relation between the deflections and the corresponding intensities, and it is only by artifices of construction that we succeed in obtaining a perceptible proportionality between these upon a certain fraction of the scale. In reality, each apparatus requires a particular graduation and a determination of a certain number of points, whence are deduced the rest through interpolation. Lippmann's galvanometers, or ampèremeters, present the peculiarity that their indications are indefinitely proportional on the entire length of the scale, and that it is only necessary to know the indication furnished by a given intensity in order to at once deduce therefrom all the rest. The new principles applied by Mr. Lippmann in his apparatus consists in balancing the electro-magnetic action of the current to be measured by a hydrostatic stress which, at every instant, is proportional to the intensity of the current. It suffices to know one in order to at once know the other.

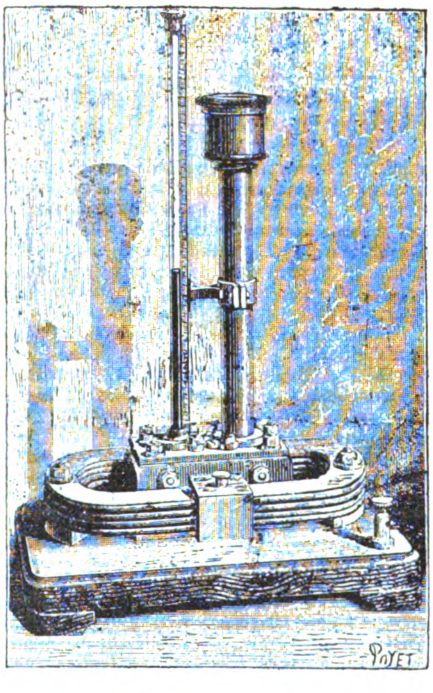


Fig. 1 gives a general view of Mr. Lippmann's ampèremeter, and Figs. 2 and 3 are longitudinal and transverse sections which exhibit its principle and mode of operation. A mercurial pressure gauge, A B C (Fig. 2), is placed between the branches of a permanent magnet in such a way that the two poles are on each side of the horizontal leg of the gauge. Pieces of iron, with ends in the form of truncated cones, serve as armatures to the magnets, and permit of concentrating the field at B, so as to render it as intense as possible at this point. The current to be measured is led to the mercury from the horizontal leg of the gauge, and traverses it vertically. It comes in through the strip of platinum, D, and makes its exit through the second strip, E. That portion of the mercurial column which is traversed by the current represents a movable current element, which, placed in the magnetic field constituted by the magnets, K, tends to move towards the right or the left. The stress exerted upon this current element is proportional to its intensity, and it therefore produces a hydrostatic action, which exhibits itself in a change of level of the mercury, which latter rises in one of the legs of the gauge until the hydrostatic pressure balances the electro-magnetic stress.

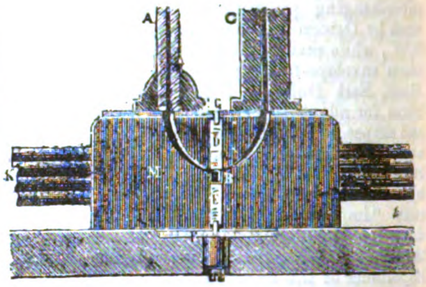
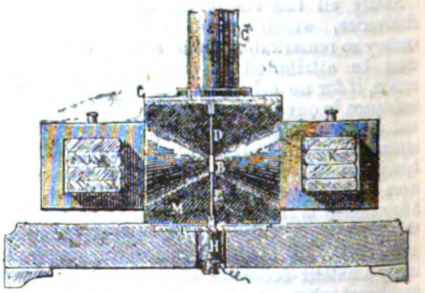




The theory of the apparatus shows that its sensitiveness is proportional to the intensity of the field, and inversely proportional to the thickness of the column of mercury. It is in order to obtain great sensitiveness that the chamber, B, is very thin, and that the field is concentrated at this point by polar appendages of conical form. In order that the reading of differences in level may be dispensed with, there is arranged upon one of the legs a reservoir of wide surface in such a way that the level in this leg shall remain constant, whatever be the change in the other leg, which is of glass of small section. The constant level leg is given a certain height in order that all the readings may be made, whatever be the direction of the current. In practice, it is convenient to so arrange the magnets that a current ascending in the horizontal leg of the gauge shall produce an ascent of the mercury in the glass leg, and a descending current produce a depression of the mercury's level. When still greater sensitiveness is desired, it suffices to incline the glass tube slightly, when a slight change of level will produce a considerable movement in the column of mercury. M. Lippmann's ampèremeter is aperiodic, in that it reaches its position of equilibrium slowly, and stops there without going beyond it. And it is reversible, too—that is to say, if the mercury be set in motion by means of an external mechanical force, and the two strips, D and E, be united by a circuit, the latter will be traversed by a continuous circuit that will last as long as the flow of the mercury does.

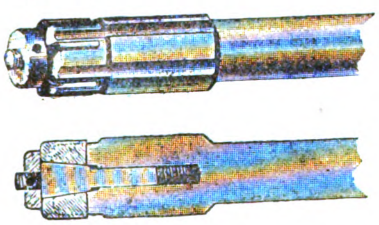
It is a true unipolar machine, that might perhaps some day be applied either as a mechanical generator of electricity, which should give little electro-motive force, but considerable intensity, on account of its feeble internal resistance, or as a standard of constant electro-motive force, in assuring of a constant flow, and a constant magnetic field that the unipolar machine would itself produce. The principle of this apparatus has been applied by its inventor to several other apparatus, and, in particular, to an electro-dynamometer and a wattmeter, which figured at the Exhibition of Electricity at the Paris Observatory last March, in the interesting collection of measures presented by Breguet. In the electro-dynamometer, a bobbin traversed by the current to be measured is substituted for the permanent magnet. Under such circumstances the magnetic field is no longer constant, but is proportional to the intensity. The result is that the changes of level in the mercury are proportional to the square of the intensity.

In the wattmeter a long, very fine-wired, and resistant bobbin is substituted for the coarse wire one, and is placed between those two points of the circuit at which it is desired to measure the expenditure of electric energy, while the mercury is, as usual, placed in the total circuit traversed by the current of intensity, I. The fine wire bobbin, mounted in derived circuit, produces a magnetic field that is at every instant proportional to the difference of potential, E, of the two points where it is fixed. The changes of level in the mercury are consequently proportional at every instant to the product E I; that is to say, proportional at every instant to the number of watts expended in the part of the circuit considered.

Aside from the originality of the principle of M. Lippmann's apparatus, they all present the valuable feature of furnishing indications which are accurately proportional to the extents to be measured, and this obliges us to use them in a large number of cases in which we could not rely upon measuring by points, a method in which so many causes of error intervene to destroy accuracy.

## BROWN'S EXPANDING MACHINE REAMER.

THE accompanying illustrations represent a new expanding machine reamer, for use where the



maintenance of standard or special sizes is essential. It is an American device, and is made by Mr. Pruyne, of Syracuse, New York. The cutters are made of the best tool steel, and are nicely fitted into unequally-spaced radial slots, cut through the end of the reamer, and bed on the conical head of a plug screwed into the head of the reamer. They are held in position more firmly by a nut on the projecting end of the plug. When it is desired to expand the reamer, this nut is backed off and the plug screwed in, forcing the cutters out the desired amount. The tool is not designed as an adjustable reamer in the strictest sense of the word, but as a standard reamer with a compensation for wear. The body is ground slightly under standard size to insure clearance, and the cutters must be expanded and maintained to that size, doing away with the objection to an adjustable reamer, that when adjusted above or below a standard size, in some special case, it is not returned to the original or standard size by the workman.

## STABILITY AND SPEED OF VESSELS.

(*Concluded from p.* 493.)

### A Problem in Mechanics.

TO explain the action of these forces, let Fig. 1 represent the cross section of a yacht in which A, B, C is the immersed portion of the midship section when at rest on an even keel. Let the centre of gravity of the entire vessel be at G, in the section taken. Let the centre of volume of the submerged portion in the inclined position indicated be at H, which point is the centre of buoyancy, and the centre of gravity of the displaced water. It is the point through which in the position assumed the upward thrust or resistance of the water acts. This point, of course, may or may not be in the cross section taken containing G, but it may be there, and it will simplify the discussion without in any way affecting the results to assume such a position of the yacht as would bring G and H into the same midship section.

Now, it is apparent that when the yacht is careened as shown in the figure, its entire weight still acts downward through G, while the resistance opposed by the displaced water acts vertically upward through H.

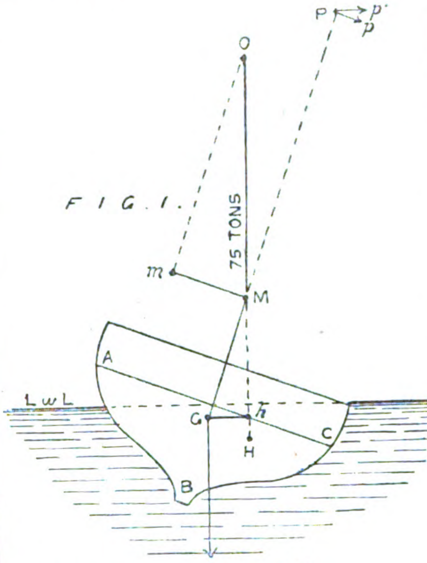


FIG. 1.

$$\begin{aligned} M\,m \times M\,g = {} & P\,p \times P\,G \\ & M\,O \times G\,h \\ & = 187 \text{ tons} \\ & = 375{,}000\text{lb.} \\ \frac{375{,}000}{27} = {} & 13{,}888 = P\,p \\ & = 6{\cdot}1 \text{ tons.} \end{aligned}$$

These two forces produce a tendency to rotation as a result of their combined and simultaneous action, one pulling down through G, the other pushing up at H, and both acting on the rigid form of the boat. The effect of the two, since they are equal in intensity, is to produce a tendency to rotation about a point midway between them, and by which the vessel seeks to regain a position of equilibrium on an even keel, and manifestly requires the action of a third or exterior force to hold it in the inclined or careened position.

From a simple principle of mechanics we know that this tendency in the boat to return to the vertical position is measured by what is known as the "moment of rotation of the couple," which is equal to the product obtained by multiplying either force of the couple by the perpendicular distance between them.

Considering the vessel free in the water, it can be shown that for slight changes of position, such as arise in practice, the vessel will careen by turning about its centre of gravity, G, which will always retain its position with reference to the load-water plane, or plane of flotation, unchanged.

The tendency to return to the vertical from the careened position may therefore be put in a somewhat simpler form for our use, for, in view of the principle first stated, the moment of the couple becomes equal to the product of the force acting upward through H, which is the displacement, or, what is the same thing, the entire weight of the vessel (so many tons or pounds) multiplied by the horizontal distance between G and H; or in other words, the tendency to return is measured by the force acting upward through H, and with *a* lever arm equal to the horizontal distance from G to H, indicated in the figure by the line, G *h*. Now the force acting downward through G may be neglected.

The question of stability consists in determining the value of this force acting with the various lengths of "lever arm" that may arise, and ascertaining for given lengths how great an external careening force in the form of wind acting abeam it is calculated to resist.

The line, G P, through the centre of gravity of the vessel, and which is vertical when the vessel is at rest on an even keel, is called "a line of rest"; it is the line along which the weight of the vessel and the upward thrust of the displaced water act in opposite directions, and hold each other in equilibrium, when the vessel is in that position (vertical) and subject to no external force. The moment the vessel careens, the "centre of buoyancy," H, through which the buoyant effect of the water acts, moves out of this vertical line to the right or left, the two forces no longer oppose each other directly in the same straight line, but their points of application become separated while their directions remain parallel, and a "couple" results. This new vertical through H, along which the buoyant effect acts, is called "a line of support," because it is the line along which the water supports the weight of the vessel partly submerged in it.

As the point, H. is the point at which the buoyant effort of the water acts, it must be the centre of volume (or bulk) of the displaced water; and the position of this point depends evidently upon the shape and configuration of the submerged portion of the vessel, and it is clear that as the vessel whose cross section is given in the figure careens more and more to the right, it submerges more and more of its hull to the right of the line of rest (or plane of symmetry), G P, and takes more and more of its bulk out of the water to the left of that line (or plane). It is, therefore, apparent that the centre of volume of the submerged part, or the point, H, must travel more and more to the right as the vessel careens, and thus increase the distance, G *h*, as the vessel continues to turn over. Now the point, M, in which the line of support, H M, cuts the line of rest, P G, is called the "metacentre" of the vessel. Its position in the vessel is important, for it will be seen from an inspection of the figure that the vessel cannot capsize, but will have a tendency to return to the upright position so long as the metacentre is above the point, G, the centre of gravity.

This results from the fact that the metacentre, M, may be regarded as the point through which the upward thrust of the displaced water (acting first through H) is brought to bear upon the line G P, where the careening force is applied (say at P). In other words, G M may be regarded as the lever arm with which the buoyant effort seeks to right the vessel, acting through M at right angles to G P, and with the intensity M *m*; that component of the "buoyant effort" which acts at right angles to G P and in opposition to the careening force at P, indicated by P *p*. It is, therefore, evident that the higher M, the metacentre, is above G, the greater will be the lever arm, M G, and the greater the advantage with which the buoyant effort seeks to right the vessel. It is for this reason that the height, M, of the metacentre above the load-water plane (or plane of flotation) is considered an important factor in yacht construction.

Let us now suppose the action of a third or external force brought to bear at some point, as P, on the line of rest, and acting in the direction, P *p'* (horizontal), and whose tendency is exerted to careen the boat to the right.

Under its action the boat will turn about the point, G, its centre of gravity, and it is evident, from a consideration of the figure, that this external force, whose intensity is indicated by the length of the line P *p'*, acts with its entire value to careen the boat only when the line of rest, G P, is vertical, for as the vessel careens under the action of this force, its effective component, P *p*, perpendicular to P G, becomes constantly smaller in proportion as the careening angle, P G R, increases; and at the same time, while the actual careening force P *p*, the perpendicular component of P *p'*, is becoming less and less as the vessel careens the point H is going further and further from G; the metacentre M further and further up the line of rest P *b'*, thus increasing the lever arm of the buoyant effort and at the same time increasing its effective component, M *m*, which resists P *p*. It is therefore apparent that an angle will soon be reached at which the buoyant effort, acting upward through H and transmitted to M (and there, we will say, acting at right angles to P G in the direction M *m*), will hold the careening force acting through P in the direction P *p* in equilibrium, and the boat will come to rest in an inclined position of equilibrium, and cease to careen. This position will be readily recognised by those familiar with sailing.

The graphical construction of these forces is simple, and will perhaps add clearness to the demonstration.

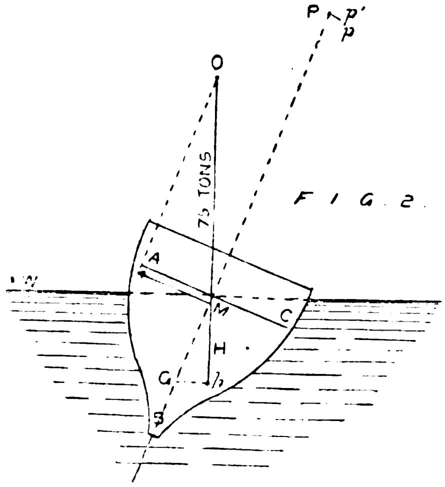
Prolong H M to O, assume a scale of equal parts in which a unit of length shall represent a given number of units of force, say five tons to the ¼in. (or any convenient scale), make M O equal to the upward thrust through H so many tons (the displacement of the vessel expressed in units of length). Resolve M O into its components by means of the parallelogram of forces acting in the direction G P and at right angles to that line. M *m* will be this component; so many tons or pounds acting in the direction M *m* through the point M with the lever arm M G, and urging the boat to the left about the point G.

The force P *p'* acting as P is the force of the wind on the entire sail area, so many pounds per square foot (depending on the velocity of the wind) for so many square feet. This entire force is laid off on P *p'* with the same scale of equal parts indicating so much force to the unit of length. P *p'* is then resolved in like manner into its components acting along G P and at right angles to it. P $p$ is the remaining effective component of P $p'$ that acts at P to turn the boat about G to the right, in opposition to M $m$ acting at M to the left. The greater force has necessarily the shorter lever arm, the lesser force the longer; both have the point G as a centre of action. From the expressed conditions we must therefore have:

$$P p \times P G = M m \times M G \qquad \text{(Eq. 1.)}$$

In a position of equilibrium the two rectangles having M $m$ and M G and P $p$ and P G for sides respectively must be equal in area, which is the geometrical interpretation of the equation of condition.

Having thus briefly determined the new conditions of equilibrium under the action of a single given external careening force, or a number of such forces having a single resultant, we find its moment of rotation or tendency to capsize the boat counteracted and resisted by a moment of rotation in the opposite direction produced by the buoyant effort of the water acting upward through H, and we conclude from the preceding that the careened position of equilibrium will be soonest reached by making the first number of equation 1 small, *i.e.*, the product P $p$ × P G; but P $p$ depends for its value upon the effect of the wind, manifestly beyond our control, while P G represents the distance of the centre of effort of the entire sail area (where the wind acts) above the centre of gravity of the vessel, but the position of this point P is fixed by the shape of the sails. It therefore seems that instead of making the first member of Eq. 1 small, we must seek to make the second member relatively large; we must try to make it so large that, for a given value of P G, P $p$ may have any possible value, without incurring the danger of their product exceeding the product of M $m$ × M G. We have therefore to ascertain how the force acting upward through H may give the greatest possible product of lever arm M G multiplied by the intensity M $m$.



$$\begin{aligned} M n \times M G &= P p \times P G \\ &= M O \times G h = 125 \text{ tons.} \\ &= 250{,}000\text{lb.} \\ \frac{250{,}000}{25} &= 10{,}000\text{lb.} \\ &= 5 \text{ tons.} \end{aligned}$$

It is clear from an inspection of the figure that this product depends, first, upon the upward thrust through H, which must remain constant in intensity, being equal, as we have seen, to the weight of the vessel, and, secondly, upon the lever arm, M G, with which it acts; in other words, the only way in which we can effect the value of the product which constitutes the second member of our equation, to increase it, is to increase the lever arm, M G, or increase the distance of the "metacentre, M," above the centre of gravity, G. But it is evident that this may be accomplished in two ways—viz., we may either lower the position of the point G on the line P G, which means simply to make the centre of gravity of the vessel very low and deep by using a lead keel or much ballast, or we may move the point M higher up by causing the point H to move rapidly to the right of G as the vessel careens, which in turn means to give the vessel a broad and shallow cross section, so that the "centre of buoyancy" in the careened position will be very far to the right of G, thus causing the line of support, H M, to cut the line of rest, P G, at a point high up above G. The latter method amounts virtually to increasing the line G $h$, which is the horizontal distance between the two centres, and it is evident this may be effected either by lowering the position of G on the line P G, or by carrying H to the right. Either way will answer so far as the theory of the matter goes; both are used in practice with good results, as we shall see.

It is clear that by making the cross section of the vessel narrow and deep, and hanging a lead keel on the bottom, we are, in fact, bringing G to its lowest possible point below the load-water plane, and are using the first of these methods. But if, on the other hand, we leave the position of the centre of gravity, G, out of consideration, and make the cross section of the boat, A B C D, broad and shallow, the point H will move rapidly to the right as such a vessel careens, and thus rapidly extends the line G $h$ to the right of G and raises the point M on the line P G, thus increasing the lever arm of the force M $m$.

These two methods of increasing the factor M G in equation 1 give us at once the principles of mechanics that underlie the deep and narrow cutter on the one hand and the broad and shallow sloop on the other. Thus are we brought in theory, by analytical investigation of the forces at work, to the same identical issue that the whittling mechanic has brought our practical knowledge of yachts through years of experiment. The analytical deductions show clearly that we may elect either of these two methods to produce the desired result. Bearing in mind the action of the different forces considered, we may proceed further to investigate the relative advantages the two methods present under given conditions in practice. The first, with low centre of gravity and narrow beam, is the usual model of the English cutter, the latter that of the American sloop. It will be seen that they differ essentially in principle, and, as might well be expected, each has both advantages and faults peculiar to its class.

Fig. 1 is a fair representation of the American sloop in cross section, while Fig. 2 represents the cutter type. In order to make our consideration of these two forms as comformable to practice as possible, the two figures with the necessary construction are draw to scale, and represent the corresponding elements of two boats having the same load-water line length, same displacement, and the same sail area nearly. The principal remaining elements are given below:

| | Sloop. | | Cutter. | |
|---|---|---|---|---|
| Length, L. W. L. ........ | 65 | feet. | 65 | feet. |
| Beam (extreme) ........ | 15 | ,, | 11½ | ,, |
| Draught ................ | 9 | ,, | 12 | ,, |
| Lead on keel .......... | 3 | tons. | 38½ | tons. |
| Lead inside ............ | 33 | ,, | 1½ | ,, |
| Ballast, total .......... | 36 | ,, | 40 | ,, |
| Displacement .......... | 75 | ,, | 75 | ,, |
| Mast (deck to hounds) .. | 41 | feet. | 42 | feet. |
| Main boom ............ | 52 | ,, | 58 | ,, |
| Gaff .................. | 35 | ,, | 39 | ,, |
| Bowsprit outward ...... | 27½ | ,, | 30 | ,, |
| Area lower sails ........ | 3000 | sq. ft. | 3450 | sq. ft. |
| Custom House bulk .... | 44 | tons. | 40 | tons. |

The centre of effort of the sail area in each (lower sails only) would be about twenty-five feet from the deck—*i.e.*, the point P at which the wind acts in both. The displacement of both boats is 75 tons, or 150,000lb.; this is the measure of the upward thrust or buoyant effort of the water in each. Let us suppose them both careened to the same angle as indicated in the figures, and ascertain the corresponding resistances afforded in each to a careening force acting through the point P to the right. The submerged portion in each cross section now becomes $a$ C $b$, but it will be readily seen that in this position the excess of the submerged portion of the boat on the leeward side of the line of rest G P over that to windward is far greater in the sloop (Fig. 1) than in the cutter (Fig. 2), and that the centre of volume of the submerged part (H) in the sloop is necessarily, on this account, much further removed to the right of G than in the cutter.

To offset this, however, the position of the point G in the cutter (the centre of gravity of the entire mass) is considerably lower down on the line of rest P G than in the sloop, owing somewhat to the shape, but chiefly to the lead keel the former carries, and this in a measure compensates for the small movement on the point H (the centre of buoyancy) to the right in the case of the cutter.

As G represents very closely the position of the centre of gravity in each case, so H also represents with little error the corresponding position of the centre of buoyancy in the two types when both are careened to the same angle. It will be observed, however, that the distance, G $h$, is considerably greater in the case of the sloop, and that the position of the metacentre, M, is consequently much higher.

In the careened position chosen we have in each case 75 tons = 150,000lb., the buoyant effort or displacement of both boats, multiplied by the corresponding distance G $h$ = $2\frac{5}{10}$ft. for one and $1\frac{66}{100}$ in the other, which for the sloop gives 150,000 × 2½ = 375,000lb. = 187 tons, and for the cutter 150,000 × 1⅔ = 250,000 = 125 tons, for the measure of the "moments of rotation" due to the upward thrust of the buoyant efforts acting along the lines of support H M, and tending to right the vessels by turning them to the left about the point G in each.

The distance G P in the cutter will be, say, 25ft., and in the sloop 27ft., the cutter having a low and long sail plan, as shown by the dimensions given, and the sloop a higher and shorter one (this, of course, considering the lower sails only, mainsail, and jib). The centre of effort being in each at the point P, and dividing the respective moments of rotation by the distance G P, the "lever arm," with which the careening force acts in the two models, we get for the sloop 375,000 ÷ 27 = 13,888lb. = $6\frac{1}{10}$ tons, and the cutter 250,000 ÷ 25 = 10,000lb. = 5 tons, which represent in each case the resistances that the internal forces are calculated to oppose to a careening force acting at the point P and at right angles to G P.

Let us suppose the sail areas in each case, or means of meeting the careening force at P, equal, or 3,000 square feet for both cutter and sloop, we have as a result 4½ pounds pressure to the square foot of sail exposed in the sloop, and only 3⅓ pounds for the cutter, to careen both to the same angle; but, as these forces are supposed to act perpendicular to the sail areas, the actual force of the wind in each case to accomplish the same result under the conditions given will, of course, be greater.

Making, then, a suitable allowance for the inclination $p$ P $p$, and the inclination of the sail to the beam of the vessel (which are never flat), these pressures would correspond to wind velocities of 30 and 35 miles per hour respectively, being in the ratio of 6 to 7 for cutter and sloop. We therefore see that for a given careening angle the sloop offers considerably more resistance to the wind or driving power than the cutter, or, what is the same thing, in a given amount of wind the cutter will careen more than the sloop, or, in common parlance, the sloop is a "stiffer boat"; other conditions being equal, she will stand up to the wind better; but not only this. It follows also, as a matter of course, that, as the wind force acting at P to drive the boat has its effective component, P $p$, diminished rapidly as the boat careens, the component perpendicular to the sail alone being available for this purpose. It therefore follows that in standing up to the wind the sloop is enabled to use a greater portion of the entire actual force of the wind than the cutter, which careens more for a given amount. The sloop has therefore more driving power for a given spread of canvas, and the cutter must carry more sail to get the same amount of propelling force.

At the same time, and for the same reasons, the cutter will doubtless stand a heavier blow with less danger of disastrous results than will the sloop, which, being stiff, will not yield beyond a given point to the gale, and is liable to lose sail or spars, while the cutter will be hove down to her beam ends, where the careening power of the wind becomes greatly diminished, but she will still be in a position of stable equilibrium, and slowly right herself as the wind ceases. A consideration of the two figures and a similar construction of the forces at work in different positions will make this clear.

For considerations of speed, however, in a wind that both can stand up to under full sail, the mechanics of the problem seem to be decidedly in favour of the sloop, whose broad beam enables her to use and derive more actual driving power from a given velocity of wind. The cutter, being hove down considerably in a moderate wind, loses much of the effective force.

Where, then, it will be asked, does the question of relative speed come in, as every one familiar with yachting knows that the cutter often rivals, and sometimes beats, the sloop in time. The answer is simple, but not of easy demonstration; in fact, it is not analytically demonstrable at all. The cutter often beats the sloop under given conditions, and the reasons for this are so complex as not to be within the bounds of exact mathematical investigation.

In a few words, the answer may be stated in general terms that the cutter, being narrower and sharper, has less resistance to overcome in moving through the water, and so compensates for other defects; but for the mere physicist it is no answer to say that when the cutter beats she does it because she goes faster, and that she goes faster under certain circumstances because she goes easier. We cannot hope to explain the matter on demonstrable grounds. The facts of the case, as yachting statistics show, are that the cutter rarely beats the sloop under like even conditions so near as they can be attained, and the results of practice seem to have fairly maintained the slight difference the theoretical principles show in favour of the sloop. The mechanical principles involved seem to incline decidedly in favour of the sloop, and practice has, in the long run, left but little question of their relative merits under the same conditions as regards speed alone.

Ever since yachts have been sailed the question has always been an open one, and both sides have strong advocates, mainly because the conditions under which the two types have been developed seemed to require the advantages peculiar to each. Wherever the principles that underlie a problem of mechanics point, as in the present instance, to two solutions, the two methods of arriving at like results will always be found adapted to different conditions that are likely to arise in practice, and the experience of years shows this to be exactly the case in the present instance.

Referring to the figures again, we see the sloop, whose chief excellence is due to her breadth of beam and consequent stiffness combined with light draught, is in every essential feature a smooth-water craft; she is evidently designed to skim over the surface of the water rather than to plough through it, while the cutter is just as evidently designed for rough water, and is essentially a sea-going craft.

The sloop has indeed great stability, but she is at the same time a quick, jerky boat; the "metacentre" rises and falls rapidly as the boat careens a little more and then returns to its former position; she rights herself suddenly at the least slackening of the wind, and is comparatively ill adapted to a heavy sea, while the cutter, owing to the slight change the centre of buoyancy undergoes in moving from one careening angle to another, is necessarily a much easier sea-going boat. She goes over on to her beam ends with perfect safety, and returns easily and gradually when the wind slackens. The same kind of reasoning applies again to the sloop, whose windward side, lifted high out of water, is subject to heavy shocks and jars from waves which are likely to impede her progress considerably in a heavy sea, while the cutter, with her straight lines, rides them easily with less change of position, or plunges through them. It would seem, therefore, natural under the circumstances and the principles involved that the cutter should be the preferred yacht with the English, who do their sailing so much at sea, and in the rough and choppy waters of the two Channels, while with us the centreboard type, more or less modified, for contrary reasons should find preference.

The question can be never definitely settled for all cases; each will always possess merits for the particular situations to which it is best adapted.

Viewed, however, in the light of mere racing machines, the question changes somewhat, as the issue then becomes one of speed alone under the same conditions for both, and from this standpoint there seems to be much in favour of the sloop against the cutter.

Speed will be the sole point at issue in the coming international race, and it would seem certainly, from theoretical data at least, that the Americans have every reason to look with confidence for the best results from their own peculiar type of boat, the centreboard sloop.

In the coming race the cutter is expected to make up for other shortcomings by her narrow beam, consequent straight lines, and low resistance to motion through the water. To offset this, however, it should be borne in mind that she is much deeper than the sloop, and that pressures (in the water) increase in proportion to the depth, and as a result of which there is probably but little gained by the narrow beam; while a sloop of moderate beam and light draught, such as the one being built by Mr. Smith to meet the Genesta, will probably be broad enough to skim over the surface of the water with comparatively light draught, and yet be sufficiently narrow to have easy lines and a compatively low resistance to motion through the water.

The mechanics of the problem seem certainly to favour such a boat. The figures 1 and 2 show practically the relative midship actions of Commodore Bennett's boat, designed by Mr. Smith, and Lieutenant Henn's cutter yacht, the Genesta, doubtless the best of her type afloat. We have looked into the mechanics of the question, where we have found that the practical yacht builder has already given us all that theory can show, and all this with a shrewd guess at the best way to overcome the resistance that water opposes to motion. Let us, for conclusion, assume his standpoint, and look at nature.

Nature has given us two types of locomotion in or upon the water, by which we may always pattern without being far out of the way. They are the fish and the duck, and the two types of yacht we have considered are in no small degree exponents of these two types of least resistance; but it will not be claimed by anyone that a yacht should sail under water or nearly so, and the most enthusiastic will prefer as a rule the type that skims over its surface. The swimming fowl has, so to speak, a broad load-water plane with light draught, its immersed section at the forward end being almost a perfect parabola; and the load-water plane of the shallow American sloop is not unlike it in plan, the chief difference being in the point where the propelling power is applied. The cutter resembles in some respects the fish, with its narrow and deep cross section and easy lines, with the propelling power equally out of place. But here the comparison ends, for though designed to offer but little resistance to motion, the elliptical cross section of the fish is doubtless mainly designed to resist severe pressures at great depths.

The question so far as the yachts are concerned will doubtless ever remain one of expediency. What do you want to do? will always be the question. Do you wish to ride out a sea without losing a spar or rag of canvas, or do you wish to hurry at any cost over a bit of easy water on a bright September day?

For the former we prefer the cutter type; but if it is a question of keeping the "cup" merely, and if there is any virtue in mechanics, we prefer the American sloop—moderate beam, light draught.

## THE LEAD BATH.

MELTED lead for heating steel articles to be hardened has become quite common in shop use. There was a time when it was employed only for articles of varying thickness, so that the part to be hardened could be heated, while that to be left annealed need not be greatly warmed; but it has been proved that a more even heat can be obtained on articles of even size, as well as on those of varying dimensions, by the lead bath, and that the heating can also be done quicker than over a charcoal fire. There is another advantage in the lead bath heating, one of great convenience at times, and that is that the article to be heated may be kept an indefinite time in the hot lead without being burned; it will not get beyond the proper heat for hardening. There is an improper use of the lead bath in the attempt to employ it for drawing to temper; the bath will do its absolute will, and as evenly and indiscriminately reduces the hardness as it heated the steel. This uniform drawing is not always desirable; there are tools and other pieces that require careful management and much humouring to bring them to their proper degrees of temper. This cannot be done in the evenly heating lead bath; the proper drawing is either over a clean charcoal fire or in a bath of heated sand. Whenever the last can be used, it is preferable on all accounts. Of course, such drawing must be done to colour, and this is one of the advantages of the lead bath for heating for hardening; the steel does not contract an oxide so thick or so discoloured that the steel itself may not be seen. In heating for hardening in a fire the surface of the steel is burned, so that it contracts a coating that must be removed by direct abrasion before the true surface of the steel can be seen. But in lead heating the lead appears to be a defence against the oxygen of the air, and the steel comes out clean. The writer has made tests that prove that the surface of machine-polished steel coming from the lead bath, and being chilled in pickle or in water, will show every gradation of colour as to temper without being previously scoured or brightened. The lead bath must be of pure lead. It will not do to use the sheet lead of old eaves, gutters, and the pipe of old drains from sinks, eaten half through with atmospheric acids and the worst corrosives of the kitchen; the lead must be chemically pure. Buy lead in pigs from the mines — the Galena brand is reliable — or buy the somewhat higher priced bar lead. Both are as nearly absolutely pure as is possible. Melt in a plumbago crucible or an iron pot. Heat the lead to a cherry red and keep it so. Cover the surface with charcoal dust. Suspend or immerse the articles to be heated in the bath until they are heated through. They need no attention until you are ready to harden them. No pewter, type metal, or junkshop stuff will do for a heating lead bath; the heat cannot be even, and the bath will not be clean. There are exceptions to the objection of drawing in the lead bath. Sometimes there are portions of an article that require softening or annealing while the remainder is left hard. In such a case the portion to be softened may be immersed in the bath and be annealed without affecting the other portions, as would be done by radiant heat.—*Scientific American.*

## PHOTOGRAPHY AND THE SPECTROSCOPE.—II.*

By Capt. Abney.

YOU now see we have a picture of this flat iron produced by the deeper blackening of the heated part, though the whole plate was given but a short exposure to the light from the phosphorescent plate. I will impress this further upon you. I have here a collodio-bromide emulsion plate. But in this case, instead of heating it by a flat iron, we will heat it by immersion in hot water. Of course, a collodion plate is not so sensitive as a gelatine plate. I put it into cold water for a short time to moisten it, and then dip half of it into some nearly boiling water; on withdrawing it, I expose it to this candle, and develop it when it gets cool, which we effect by placing it a short time in cold water. It will be seen that the part immersed in hot water is much blacker than that which was exposed cool. If I heat the plate, and allow it to cool, and then expose, there will be no effect. The plate will develop normally, for the increased amplitude of vibration will have ceased, and the light will have to perform the same work on each part of the plate. Now, in whatever manner increased amplitude is given, when the cause of the increased amplitude is withdrawn the amplitude will cease in the same manner. One of the chief reasons against what we may call the "vibration theory" of the photographic image, namely, that the molecule is unaltered by the action of light, is this—that the increased amplitude would cease with the same rapidity with which it would cease when the hot iron was applied to the back; that is to say, after five or ten minutes the amplitude of the vibrations would come back to the normal extent, a condition which is not fulfilled in the photographic image. I can illustrate this in a very visible manner. I think you can all see this phosphorescent plate. Now, what is the reason of that phosphorescence taking place? It is that the atoms of the molecules which comprise this phosphorescent material are swinging in a certain rhythm, which gives us the sensation of light. Now, if I apply a hot iron to the back of this plate, I think at once you will see that the image of the hot iron is present. Here is the same kind of action taking place in the one case as in the other. Now we come to another point, which is a slightly different one, and that is the energy of radiation. I may say that the energy of radiation is a subject on which I could discourse for a good many hours, but here I can devote but two minutes to it. I must try to make it as clear as I can. I hold in my hand a little instrument which is called a thermopile, which, you see, has a narrow slit, which could be narrowed to any degree of fineness; attached to it is a screw motion, which will make that slit travel along the base of the instrument; beneath that slit are some thermo-electric couples. It is not my business to enter into how they are made, but still we know that, when thermo-electric couples are heated, an electric current is generated sufficiently strong to cause the needle of a galvanometer to deviate; and the amount of energy of radiation which falls upon the face of the pile can be measured by the deviation of the galvanometer needle. In a great many experiments which were made, this thermopile was caused to travel along the spectrum by the screw motion, and at every part of the spectrum, at distances of, say, a quarter of a turn or half a turn of the screw, the amount of deviation which was given to the galvanometer needle was read off. By that means we are able to compare the energy existent at different parts of the spectrum. On measuring the area of the curve in which lie all dark rays, and the area of the curve for the visible rays, it will be found that, roughly speaking, the energy of the latter rays are about half that of the former. But for photographic action we do not have anything like that amount. The red rays for ordinary photographic work are useless; and why that is we shall see by-and-by. We will say that the photographic action stops at the blue, and we find that the total energy of radiation which is used for photographic purposes in the electric light is only about one-hundredth part of the whole energy of radiation. The remaining ninety-nine parts are wasted as far as photography is concerned, except in so far as they heat up the molecules in the same way as the flat iron heated up the molecules on the photographic plates. The other curves show the energy of incandescent lamps. You will see that they have very little of what is called actinic power; that is to say, they have very little blue ray at all compared with the arc light. In the lowest curve we have a lamp at only a yellow heat, the middle curve being that at a white heat, and you will notice the enormous difference there is in the energy between the two. The energy of the middle curve, which measures the total energy of radiation from the incandescent light, is about twelve times that of the visible power. Yet, when you have to measure the photographic part of the spectrum, you will see that it is only about eighty. That is to say, supposing you have a filament of an incandescent lamp which is one-hundredth of an inch wide and half an inch long, then if you take an arc electric light and cut off from the glowing positive pole the same area, the photographic value of the one, area for area, is about eighty times that of the other. I will ask my assistant to put in front of the slit something which I showed you at my last Cantor Lectures, and which I daresay you have forgotten all about. That something is a film of the same silver salt with which I photographed the spectrum at the commencement of the lecture. You see that it cuts off all the violet, and well down into the blue. I want to show you that the colour of the photographic spectrum is perfectly different from that which the human eye can see. I wish to show you a little device by which, perhaps, I shall be able to give you an idea of the integrated colour. A tolerably bright spectrum is on the screen of the camera; I raise the screen so that the spectrum falls on a lens placed a little beyond it: and if we had time, I dare say that we should be able to get a screen placed in the focus of the second lens, so that the recombined colours would form a white patch, without the slightest tinge of colour. We have got a white circle, however, which is sufficient for our purpose, though at one margin there is a very narrow red fringe to it. In the place where the coloured spectrum is in focus I place a horizontal aperture, about ¼in. wide, and by a little arrangement I can, by strips of card, cut off any colour I like from falling on the collecting lens, so that it recombines only the remaining colours. You remember that the photographic spectrum does not extend as far as the green, ordinarily speaking, so now I cut off all rays as far as where the photographic spectrum begins, and you can see the colour of the light, which is really useful for photography. It is a sort of sea-green colour. If I were to take that light, and pass it through a slit and a prism, you would soon find that the whole of that spectrum would be photographically active, because all the light which is not photographically active has been cut off. I will show you one more method of recombining the photographically effective colour disc; that is by taking the ordinary disc, and cutting out the red and orange. We have, then, only the green, the blue, and the violet; and those, when they are combined together, ought to give you pretty nearly the integration of the colours which are ordinarily photographically active. I will ask my assistant to spin it in front of the lantern. I do not know whether you can all see the colour-charts which I hold in my hand, but those who can will see that the colours, when placed in the blue-green light, appear totally different from what they did in the whiter light. The yellows are much deepened, and the reds are blacker. I will ask now to have the spectrum thrown upon the screen once more, and we will again pass this colour-chart through the spectrum. The colours are very pure for pigments. I think that it is the finest colour-chart of the spectrum which I have ever seen. It is one prepared by Professor Piazzi Smyth, and appears in his Madeira spectroscopic observations. Notice that the blue appears perfectly black when the chart is in the red, the red at the left hand being brilliant. Passing it into the yellow, the yellow is vigorous; the blue is black, and the red undimmed. Upon my passing it still further on in the green, you will see that the red is blacker, and the orange is blacker, whilst the yellow still keeps its colour, and the blue begins to get more bright. Passing it still further on into the violet, we see that the yellow is now perfectly black, the red has gone, and the blue begins to shine out. Passing still further, you will see that the blue still shines out, but is less intense, all the other rays appearing black. Upon my passing it again rapidly through, you will now be prepared for the changes that take place. In this lantern, which has been used to form the spectrum, the light passes through a slit. The slit, you see, is perfectly straight, with parallel edges. Now comes the question, "Is it necessary that light, in order to be decomposed into a spectrum, should be passed through a slit of this description, or what shapes may it be allowed to take?" I propose to try to answer this query in an experimental manner a little. First of all, we will see what the effect will be if we use no slit at all. You see that the colours are not pure. I replace the slit, and you will see at once that we now have, not the various colours overlapping, but a tolerably pure spectrum. Now let us take a slit of another shape—a zigzag slit; and here we have another form of spectrum delineation of the rays. Placing a metal in the arc, the bright lines due to the vapour flash, and, it will be seen, take the zigzag form of the slit. There is, then, no particular reason for using a straight slit, except convenience. Then, again, I may take a ring slit, and to test its value we will put a little silver in the arc to show you. I am not simply showing this as a pretty experiment, but I want to show you that such a slit is absolutely useful in photography; the spectrum of silver now on the screen shows rings of different coloured rays. It is a very pretty spectrum. This form of slit is extremely useful in one branch of spectrum analysis. You are perfectly aware that, during a total eclipse, the body of the moon covers the sun; but that there are seen beyond the dark moon certain red protuberances which belong to the sun, and are known as "prominences." It has been the work of astronomers to determine the composition of those protuberances, and also to form a definite idea of the corona of light which surrounds the body of the sun, and can only be properly seen during a total eclipse. The picture on the screen is a representation of the total eclipse of the sun as observed in Egypt in 1882. It is a negative picture, and of course the dark halo which you see around was seen as a bright halo, and the white disc is the black moon. On the left-hand bottom corner you may notice the comet which was discovered during the eclipse, and which received the name of Tewfik, after the Khedive of Egypt. Round the disc of the moon are little prominences. Those prominences are vastly more bright than the corona itself, which is the halo extending some distance round the sun. Thus we have a bright ring of light round the moon surrounded by a feeble light. The former, when viewed by means of a lens in front of which a prism is placed, shows rings of colour composing these prominences, and of course these rings can be photographed.

---

* The substance of the Cantor Lectures delivered before the Society of Arts.

## THE HANDLING AND DEVELOPMENT OF DRY PLATES.*

THE subject will be briefly treated under three heads: the man, the light, and the development.

And first, in regard to the man, though qualified to go through successfully with the various manipulations connected with the production of gelatine negatives: The critical dicta that, "any one can make dry plates, but it takes a genius to develop them," or that "one science only will one genius fit. So vast is art, so narrow is human wit," are rather sweeping to apply to development, which is only a branch of science; but still, the higher the mental training, and the more perfect the command of all the faculties, the greater will be the success of our man. But no great thing is achieved in a rush; there is a great deal of preparation, a succession of events, preceding a crisis, or a great achievement; so that the guiding hand and the governing will, to be successful, must be disciplined by previous habits and modes of action. One must be ready for the decisive moment wherein the fit achieves success, the unfit suffers defeat. In the tide of one's affairs, how can he take it at the flood, if he has neglected his schooling in the methods which guarantee success?

### The Light.

In the attainment of perfect chemical results, the management of the light is of supreme importance. It matters not how perfect the plates, the lens, or the development may be, if the lighting is defective the result will not be a first-class negative; for in such cases, with the best materials, only a map representation can be obtained. In portraiture, should one so light the face as to have crescents in the eyes, with possibly stars in the pupils for high lights, perfect modelling or definition is out of the question, because the same flood of light which has made a caricature of the eyes has utterly obliterated the delicate curves about the most important features of the face. This criticism is made because too many photographers, even to this day, have these defects, and judging from these too many what are considered first-class galleries use the same quantity of light for dry plates that was found absolutely necessary for the wet. This charge lies mainly against those who, having clung to wet plates till they were compelled by the force of circumstances to use the dry, have gone off on a tangent trying to make all sorts of difficult positions without head rests, and to achieve this they flood the subject with so much light as to sacrifice definition to effect. But it is now possible, without risk of the subject moving or of underturning, to model up the subject with light somewhat as a painter or sculptor would under similar conditions. This can readily be accomplished if the light is brought under absolute control by properly curtaining the skylight. For a twelve foot light there should be at least two curtains for the sidelight and two restrictively fastened at the top and bottom of the top light. With such an arrangement the light may be so adjusted as to bring the high lights in the eyes to a mere point, and, if at the proper angle, the whole face will be so lighted as to give good modelling and, with proper timing, good definition. Under such conditions the pupils will not contract nor will the subject frown. But what light you have, have it clear and brilliant, as it is folly to talk of brilliant chemical effects without a brilliant light. Proper or full timing will give all the softness required. Use rapid plates and light boldly for relief and brilliancy. Silver plates demand too much light or too prolonged timing to get the best results as to either definition or expression. In regard to the exposure, the only safe criterion is the relative brilliancy of the images on the ground glass; and one should school himself to judge critically of the brightness and colour of the image, decide that this subject requires so many seconds, more or less. Rely on and cultivate your judgment; there is great demand for it in lighting, posing, &c. If one cannot put confidence in himself, who should?

### The Development.

This shall be confined to my present methods of procedure, stated as concisely as possible. Two kinds of development are used:

### The Ammonia Pyro.

| | | |
|---|---|---|
| Sulphite of soda (crystals) | 6 | ounces. |
| Bromide of ammonium | 1½ | " |
| Bromide of potassium | 2 | " |
| Pyro | 4½ | " |

Dissolve thoroughly, and add sulphuric acid, 240 minims; and liquid ammonia, 6 ounces, and enough water to make 80 ounces solution. Use 8 drachms of this stock solution, and from 8 to 11 ounces water.

### The Soda Pyro Developer.

| | | |
|---|---|---|
| A.—The pyro portion—water | 96 | ounces. |
| Acid | 96 | grains, dissolved |
| Alcohol | 6 | drachms |
| Pyro | 16 | ounces |
| B.—Soda portion—water | 120 | ounces |
| Carbonate of soda | 16 | " |
| Sulphite of soda (granulated) | 16 | " |

Use 1½ to 4 drachms of the pyro solution, 8 of the soda, and 7 ounces water. The ammonia pyro and the pyro portion of the soda developer are kept in 6-ounce bottles, and will keep indefinitely. Ordinarily the developers are mixed as follows: 3 drachms of pyro solution, 8 drachms of soda, and 7 ounces of water; the ammonia pyro 8 drachms, and 8 ounces water. The trays are used in developing the smaller sizes; partly for expedition, and partly because slight modifications may be made quickly in the mode of development. The timing is judged to be absolutely right, but a little short, the soda developer is poured into the tray and the plate placed in it. Should development progress too rapidly, place the negative in it, or the tray into which some ammonia pyro has been poured. Should the timing be considered a little full, start with the ammonia pyro first. If the exposure be first right, the ammonia pyro brings up the image almost as rapidly as in wet-plate development, and the negative has a light straw-colour bloom with excellent printing qualities. Should its exposure be much too short, it gives too much colour and contrast. In such cases the soda developer is far superior. With the two developers combined in various proportions many modifications may be made. There is a peculiar relief or atmosphere effect given to the negative, which is distinguishable from that of either alone. In developing 18 by 22 or 20 by 24 plates, the ordinary method is modified in the following manner: In the 16-ounce bottle is mixed 3 or 4 drachms of the pyro solution, 2 ounces soda solution, and the bottle filled with water. Into another 8-ounce bottle is poured 3 drachms pyro solution, 1 ounce soda solution, and filled with water; into another 8-ounce bottle, 1 ounce ammonia pyro, and the bottle filled with water. The developing tray is partly filled with water and the plate placed in it and allowed to soak for a few moments, or until the water will run off without ridging, when it is quickly poured off, and the developer in the 16-ounce bottle is dashed on, and the tray rocked to secure even development. Should the exposure prove short, this developer weak in pyro will save it; or the exposure proving about right, pour it in 8 ounces of normal soda solution; or if full exposure is indicated, use instead the 8 ounces ammonia pyro solution, which will check rapid development and give intensity without making a slow-printing negative. It has been noticed in the development of large plates, when the developer is in any ways near the right power or strength, the image will come up quite rapidly at first, but will soon check up and proceed quite leisurely, and the mode of procedure prove just right. But if the shadows come up too much before the checking of it begins, without the addition of more developer stronger in pyro, the negative will have to be over-developed to get printing strength; or if the stronger pyro solution be added when really it is not needed, the negative will then have too much contrast, and, if not speedily checked, too much intensity also. It takes an exceedingly quick apprehension to realise in time to correct a mistake made in the commencement of development, and what modifications are necessary to redeem the negative. It is simply impossible in all cases to begin development just right. Ample preparation should be made for all contingencies, as one should not rely too much upon his wit to help him out of a tight box; and yet his mother-wit may be the *ultima thule* in the redemption of an otherwise hopeless situation. The great thing is the ability to comprehend the situation in each particular case, the readiness to make possible modifications, and the grit and alertness to make them in time. It takes a brave man to avoid getting rattled and winding up with a negative too thin, too intense, or with too much contrast.

We will close with an answer to the question "Does rocking the plate during development secure contrast?" That evenness and cleanness are obtained by it is not questioned, so directly to the answer. The molecules of bromide of silver disturbed or changed, by a proper exposure from the highest light to the deepest shadow, are in progressive diminution. All, or nearly all, of the bromide of silver on or near the surface of that portion of the plate which represents the highest light is changed, while but a small amount is a light effected in the deepest shadows. These mechanical agitations of the developer cause a more rapid chemical action, so that before the developer has had time to penetrate the film to any considerable extent the reduction in high lights has been carried to a much further point than it otherwise would had the developer remained quiescent. The start the high light has secured over the shadows is maintained throughout ordinary development; also the shadows requiring all, or nearly all, the changed silver, both in and on the surface of the film, to give proper definition, the high lights have time to darken sufficiently to produce proper contrasts. But there is still another factor contributed to the same result. The greater amount of free bromine thrown off in the high lights, and combining with the quiescent developer lying immediately over the high lights, retards development in the lights, which, in the shadows, the developer being less retarded from this cause, progresses too rapidly to secure contrasts, but by agitation the power of the developer is kept uniform over the surface of the plates, and the high lights retain all other advantage secured in the exposure.

---

* By W. H. Potter, in the *Photographic Times*.

## SCIENTIFIC NEWS.

THE death is announced of the Rev. John Baron, D.D., rector of Upton Scudamore, aged 68 years. Dr. Baron was the author of several works, amongst them "Scudamore Organs; or Practical Hints Respecting Organs for Village Churches."

Dr. Henry William Reichardt, the distinguished botanist, and professor of botany in the University of Vienna, died while in a fit of temporary insanity last week. Dr. Reichardt was an occasional contributor to English periodicals, but the majority of his papers were published in the *Journal* of the Vienna Academy. He was born at Igiau in 1835.

Dr. R. H. Gilbert, the inventor of the elevated railroad system of New York, died recently in his 53rd year. After serving in the war of the Rebellion, Dr. Gilbert devoted all his time to the rapid transit problem. He first got up the pneumatic tube system, but abandoned it finally as impracticable. He then brought out his patent for an elevated railway, and obtained a charter for a road through Sixth Avenue and Second Avenue. The patent was for an arch thrown from one side of the street to the other, upon which a local train and a through train were to run on independent tracks, and which would afford a support also to the telegraph wires. It was some years before the work was begun, but Dr. Gilbert's unremitting efforts in the United States and Europe finally created confidence, and the required money was eventually obtained. The structure in Sixth Avenue was begun, rapidly carried forward, and on May 1, 1878, the first car was run from Trinity Church to Fifty-ninth-street.

Dun Echt Circular No. 96 says that a telegram from Professor Krueger announces the discovery of Tuttle's comet by M. Perrotin, at Nice, the observed place being G.M.T., Aug. 9·6124, R.A., 7h. 23m. 43·1s.; N. Dec., 28° 1′ 24″.

In No. 2,675 of *Astronomische Nachrichten*, Dr. E. Lamb gives an orbit of Barnard's comet which will reckon as Comet II., 1885, the return of Encke's comet reckons as No. I. Dr. Lamb makes the perihelion passage on August 9 at a distance from the sun of 2·5 in terms of the earth's mean distance, which it will be seen differs considerably from other computations.

The Institution of Mechanical Engineers during last week held their summer meeting for the first time in Lincoln, and the Mayor, in welcoming them, said that the city owed much to mechanical engineers, who in the course of 30 years had transformed a quiet cathedral city into the most important centre for the production of agricultural engines and machinery. The address of the president, Mr. J. Head, was read by the secretary, and forms a valuable contribution to the literature dealing with the relative advantages and disadvantages of iron and steel for various classes of constructive work. A number of interesting papers were read, including one of special value, in which Mr. R. C. Neville, of Wellingore, detailed his experiences with a private installation of electric light—viz., 125 incandescent lamps fitted in his own house. The discussion in connection with this paper turned chiefly on the modified form of Richardson's electric regulator. Dunbar and Ruston's steam navvy was also the subject of a paper by Mr. Joseph Ruston, M.P. Several visits were paid to the important works in the city and neighbourhood.

Mr. Arthur Smithells, of Owens College, Manchester, has been elected to the professorship of Chemistry at the Yorkshire College, Leeds, vacant by the retirement of Dr. Thorpe, who becomes Professor of Chemistry at South Kensington.

A lectureship of comparative embryology is to be instituted at Edinburgh University, and the Senatus has appointed Mr. G. Brook, F.L.S., subject to the approval of the University court.

The recently-founded Scottish Geographical Society purpose to form a loan collection of maps, plans, itineraries or guide-books, and views relating to Scotland, for exhibition at the Aberdeen meeting of the British Association next month. The address of the secretary is 80A, Princes-street, Edinburgh.

The International Geological Congress, whose meeting was postponed last year, owing to the epidemic of cholera in Southern Europe, will hold its third meeting at Berlin on September 28, under the honorary presidency of Prof. H. von Dechen.

Two important papers on cholera have been recently published—one from the pen of Professor Burdon Sanderson, based on the lecture he recently delivered before the Royal Institution; the other by Dr. Cameron. Professor Sanderson considers that cholera, like other epidemic diseases, owes its power of spreading to a living and self-multiplying organism, though he hesitates to admit that Koch's comma bacillus is the specific organism. The liability of a locality to attacks of cholera depends on the physical character of the soil, and on certain changes which it undergoes in the course of the seasons; but no combination of soil and season will produce a harvest unless the seed has been sown. Dr. Cameron accepts the bacillary hypothesis, and contends that Dr. Ferran's inoculations have done as much to prevent cholera as vaccination has to prevent smallpox.

At a recent meeting of the San Francisco Microscopical Society, Dr. J. M. Selfridge read a paper on "Bacteria, and their Relation to Health and Disease," in which, after recounting the views of the authorities, he stated his opinion that bacteria are the result, and not the cause, of the decomposition of organic substances. An "exceedingly animated discussion" followed, and it is expected that more papers on the subject will be forthcoming. Professor Hanks presented two slides of gold from quartz collected by him at the mines near Dahlonega, Georgia. The peculiarity of the gold consisted in its crystalline condition, its purity, and its absolute freedom from coating. Slides of this material will be furnished to members interested, and we presume that mineralogists and others can obtain specimens. Mr. A. H. Breckenfeld is the secretary of the San Francisco Microscopical Society.

An expedition under the auspices of the Royal Dublin Society and the Royal Irish Academy, the latter bearing all expenses, left Queenstown lately on a dredging excursion in the Atlantic, 120 miles west of Cape Clear. This is the first deep-sea expedition of the kind from Ireland, and much interest will be felt as to the result of its operations, which altogether occupied five days. A detailed report will be presented to the Royal Irish Academy.

The Sadlers' Company have established four studentships, each of the annual value of £30, and tenable for two years, at the Finsbury Technical College of the City and Guilds of London Institute. The studentships will be competed for at the entrance examination to be held at the college on October 1, and are open to pupils above 14 years of age who are attending or who have attended any public elementary school in the United Kingdom.

M. Chevreul, the oldest chemist in the world, reaches his hundredth birthday on the 31st inst., and the Parisian students intend to have a special celebration of the event.

Chloride of zinc used as a soldering fluid is said to poison the contents of the tins in which food is sealed, and an inventor has patented a solution of lactic acid and glycerol in water as a soldering flux which is said to be perfectly harmless. If any of our readers try it, we shall be glad to hear the results.

The Board of Trade has declined to permit the opening of the Blackpool electric tramway on the ground of faulty construction; but it appears that the blame does not rest with the electrical engineer.

M. Carnot, in the *Bulletin* of the French Society for the Encouragement of National Industry, says that an alloy of 75 copper, 25 manganese has no tendency to form cuprous oxide, which causes the formation of soluble salts, which in turn accelerate the corrosion of copper sheathing on ships. This surface corrosion of copper has always been considered an advantage by those who like to have their vessels as free from barnacles as possible.

The *Etruria* has made the passage from New York to Queenstown in 6 days 9 hours—the quickest on record.

The Municipality of Paris has voted the requisite funds for the erection in the cemetery of Père La Chaise of three cremation ovens, which will together be capable of reducing to ashes twelve bodies per day. The ovens are to be constructed purely by way of experiment, and are to be used only for consuming the bodies of hospital patients who—being owned by nobody—after their decease find their way to the dissecting-room.

## LETTERS TO THE EDITOR.

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* **EDITOR** *of the* **ENGLISH MECHANIC**, *332, Strand, W.C.*

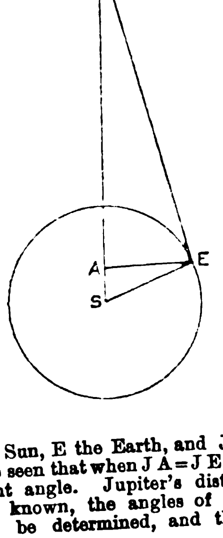
*All Cheques and Post-office Orders to be made payable to* J. PASSMORE EDWARDS.

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original."
*-Montaigne's Essays.*

### THE EQUATION OF LIGHT—A CHEAP TELESCOPE—WHAT IS "CREATION"?—ARE "TWO EYES BETTER THAN ONE"?—AN INSOLUBLE PROBLEM—THE CINCINNATI OBSERVATORY REPORT ON THE COMETS OF 1883—WHAT RENDERS TERRESTRIAL OBJECTS VISIBLE AT NIGHT IN A TELESCOPE—A POCKET FIELD MICROSCOPE—PLACES OF DOUBLE STARS, &c.—AN INSTRUCTIVE FORM OF WEATHER CHART.

[24590.]—THE formula given by "Light" (query 57120, p. 463) is quite correct, if it be desired to find the heliocentric time of a minimum of Algol, but scarcely so as applied to the Eclipses of Jupiter's Satellites: for (see figure)



If S be the Sun, E the Earth, and J Jupiter, it will easily be seen that when J A = J E, E A S is not really a right angle. Jupiter's distance, however, being known, the angles of the triangle J E S must be determined, and then S A by plane trigonometry.

I was as grieved as I was astonished to hear that the well-known 9in. reflector, belonging to the late lamented Prebendary Webb (speculum, tube, Berthon mounting, circles, eyepieces, and all) was sold the other day at Hardwick for £6 10s.!

[The above two paragraphs were for some reason omitted from my letter (24537) on p. 473.]

"H. B. F." (letter 24552, p. 477) must forgive me for saying that his use of language is of a very lax description. When I say that gravitation keeps the earth in its orbit, I simply predicate something of a phenomenon. When he attempts to account for certain facts in evolution by ascribing them to "creation," he lugs in a *final cause*, of which he can know less than nothing. "What is the secret of the appearance of so-and-so?" "Creation." "What is the cause or operative agent in Creation?" "The Creator." "Well, and how came He into existence?" and so on, *ad infinitum*. This is not Science, whatever your correspondent may think.

I rather fail to see how Mr. Kennan's contention in letter 24561 (p. 480) invalidates Mr. Nelson's statement in his previous communication (24511). Surely Mr. K. does not mean to contend that a man looking through a monocular telescope sees more when his unoccupied eye is open! If he uses his unoccupied eye, the view of his observatory dome, &c., which he will get with it will scarcely tend to improve the vision of the one looking through the telescope. I invariably observe with both eyes open; but by long practice I have brought myself to see nothing with the one not in use at the telescope. It is much more comfortable to observe in this way; but that is all.

"R." (query 57122, p. 485) must, one would fancy, see at once that his own data are insufficient for the trigonometrical solution of his problem, because the position of C is not given. If he were to move the foot of his 50ft. ladder 43ft. or so out from the wall, the top of it would touch his wall AB some 25 or 26ft. up; but if he brought it within 17 or 18ft. of B, then would the top of the latter touch AB more than 45ft. up, the ladder in each case resting upon the edge of his porch E.

The Cincinnati Observatory has just issued a volume of "Observations of the Comets of 1883," which will be found of very considerable interest to all students of the strange and erratic type of celestial visitants of which it treats. It embodies the results of the observations of Comets I. and II., 1883, made there by Mr. H. C. Wilson, while acting, *pro illâ vice*, as Astronomer at Cincinnati. The observations for the determination of the places of the comets on successive nights call for no special mention; but those of their physical structure and aspect are well worth studying. Any of my brother readers who may have made careful sketches of the Pons-Brooks Comet during the end of 1883 and the beginning of 1884, who will compare them with the numerous and admirable lithographic reproductions of Mr. Wilson's drawings which illustrate his text, will be struck with their wonderful fidelity. This is very notable in small matters of detail. "It is confidently hoped," says Mr. Potter, in the concluding clause of his preface, "that the present publication will prove a welcome addition to our knowledge of these wonderful bodies, and materially aid in the solution of the problem concerning their physical constitution." Readers of the volume which that preface introduces will admit that the hope thus expressed has been justified.

I, and many others, have to thank Mr. Sadler for his reproduction in letter 24564 (p. 497) of Professor Holden's curious record of his experiments on the light-grasping power of a large object-glass at night when directed to a terrestrial object. But I think that most people who have devoted any attention to the subject will agree with Mr. Holden in the words of his peroration that, "So far as I know, there is no satisfactory explanation of the action of the ordinary night-glass, nor of the similar effect when large apertures are used." For, irrespectively altogether of the enormously greater amount of light concentrated by a large object-glass in comparison with that which falls upon the unassisted pupil, I am certain that mere *magnification* acts in some way in rendering things visible after they have ceased to reflect sufficient light to be fairly discerned with the naked eye. To give a simple illustration: My thermometers hang in a frame attached to the external north wall of my observatory. Now I sometimes go out when the twilight has so deepened that I cannot see a division on their scales; but by the use of a little pocket lens I am enabled to read them without difficulty. This appears to me to be a subject deserving discussion.

The water microscope described by Mr. Hippisley in letter 24586 (p. 502) was invented by Stephen Gray, at least as early as 1696 (*Phil. Trans.* No. 221, p. 280). Prior to this Hooke, in his *Micrographia* (published in 1667), thus describes his method of making globule lenses, which any one can manufacture for himself, and which have the advantage of being permanent. "If," says Hooke (loc.cit.) "you take a piece of clear Venice glass, and, in a lamp, draw it out into fine threads, and then hold the ends of these threads in the flame until they melt; they will run into a small round globule or drop, which will hang to the end of the thread. Having made a number of these, they are all to be stuck upon the end of a stick with a little sealing-wax, with the threads standing uppermost; these ends are to be ground off first on a whetstone, and then polished on a metal plate with tripoli. The lenses thus finished, if placed against a small hole made in a thin piece of metal, and fixed there with wax, will both magnify and make some objects more distinct than any of the great microscopes can do." A lens of this sort—or several of varying powers—might well be fixed in Mr. Hippisley's V-shaped metal strip, and carried in the pocket for instant use whenever required. For a permanent fluid lens see Mr. Beck's remarks reported on p. 299.

Mr. Ruthven appeals to me personally in query 57186 (p. 507) to give him the accurate places of certain stars; but several I quite fail to identify, and writing away as hard as ever I can to save Friday night's post, assuredly cannot wade through many volumes to do so. Notably is this the case with his three B.A.C. stars; for, as far as I know, the B.A.C. numbers are never given in Webb at all. Two only of his objects can I find easily. The first is T. Coronæ, of which the Mean Right Ascension and Declination on Jan. 1, 1885, were 15h. 54m. 42s., and 26° 14′ 54″ north respectively, and Σ Neb. 6 (Tauri Poniatovii) of which the mean place at the same date was 18h. 0m. 32s. and 6° 49′ 29″ North. The co-ordinates of objects given in "Celestial Objects for Common Telescopes" to the nearest minute, both of time and arc, are amply sufficiently accurate, though, for finding them with any moderate power. Perhaps Mr. R.'s telescope is not powerful enough to divide the stars and so furnish means of identifying them.

That well-known amateur and occasional contributor to these columns, Mr. J. Rand Capron, F.R.A.S., of Guildown, Guildford, has just issued, for private circulation, a most ingenious and instructive chart, which exhibits at a glance the whole of the atmospheric and other meteorological conditions for every day in the year 1884. The days of the year from the abscissæ, and the heights of the barometers and thermometers, depth of rain, sun hours, wind direction and force, &c., &c., the ordinates, by the aid of which curves are laid down representing the sequent variations in the meteorological states of the Guildford climate during the past year. Of course one has often seen barometric curves, and those of temperature and the like described in this way; but it is the combination of the whole of the instrumental indications in one chart (or rather two, for it is in halves) which seems to me to be such a useful feature. The copies that I have seen are apparently photographic facsimiles of the original.

**A Fellow of the Royal Astronomical Society.**

## NEW (?) DOUBLE STAR IN CORONÆ.

[24591.]—I undertook the other evening to look at the new double star discovered by Mr. Gaudibert (letter 24439, p. 410). I think there must be an error in the place given, and that Mr. Gaudibert has been examining some known pair which he has failed to identify for that reason. There is not only no double there, but no star of the magnitude described. The brightest in the immediate vicinity is but little, if any, brighter than eighth magnitude. The only pair of any consequence near is Σ1964, but that differs entirely from the one described, and has a different R.A. and decl.

Chicago, July 28. **S. W. Burnham.**

## 36 OPHIUCHI.

[24592.]—While the matter of 36 Ophiuchi is before your readers, I would like to ask whether the variability of either of the components has been definitely settled upon as yet. I find this star was observed by me on June 22, 1883, with my 4in. equatoreal, by Cooke, p. 120, and the following notes were made:—

10h. 12m. Clear and beautiful. A double in field, magnitudes nearly equal; about 5½, distance 5″. Counting the preceding star as A, position about 40°.

At the time I was under the impression that 31 Scorpii was under observation, the telescope having been set for that object; but the instrument, having been only recently remounted, was not in very accurate adjustment, and as this double was noticed at once it was taken to be the star sought after. After making the notes I turned to Webb, out of curiosity, to see how the observations compared; but was much surprised to find such a difference in magnitudes. A more careful observation was then made, and the following additional notes entered:—

If this is really No. 31 the magnitudes and position are certainly different from Webb. The companion is nothing like an 11th mag. star; it is fully equal to the other, and difficult to tell which is the brighter. By a more careful estimate I make the possible angle about 30°, counting the preceding star as A. There is a distant 6½ or 7 magnitude star, n.p. about 3′, pos. about 315°.

Afterwards I looked into the matter more fully, and was convinced that the star really observed was 36 Ophiuchi; but still the magnitudes differed from Webb much more than any other observation made on the same night. Whilst the absolute brightness might not have been exactly 5½, yet I am satisfied that if either of the stars had differed from the other by half a magnitude, or even less, the difference would have been so perceptible that I would not have been under the necessity of designating the star from which the positive angle had been estimated as the *preceding* one.

Both the "Handbook" and Webb speak of one or other of the stars being suspected of variability; but I cannot find it in "Gore's Catalogue," nor in any other catalogue that I possess. The positive angles and distances above were estimated, not measured. **W. H. Numsen.**

Baltimore, U.S.A., July 31.

## DAYLIGHT OCCULTATION OF ALDEBARAN.

[24593.]—It is difficult to understand the meaning of the first paragraph of Mr. Pearson's letter of August 1, when taken in connection with my previous communication on the same subject. It appears that he is confusing the prediction of the circumstances of an occultation with the times obtained by actual observation, which, as given by me, are those when the immersion and emersion took place as recorded by a sidereal chronometer, previously rated by transits for local sidereal time.

Of course, as Mr. Pearson says, the times of immersion and emersion will vary very perceptibly at places in different geographical positions, and it is this very difference in time from Greenwich, obtained by observation, which is so valuable to the traveller in enabling him to compute his longitude.

Though I am at all times willing to receive advice from experienced astronomers, I must say that I think it would have been well if Mr. Pearson had made himself thoroughly acquainted with his subject before assuming to himself the rôle of mentor. **C. E. Peek, M.A., F.R.A.S.**

Rousdon Observatory, Devon, Aug. 7.

## ASTRONOMICAL.

[24594.]—In reply to Mr. J. W. Ruthven (query 57186, p. 507) I give the places of the objects named by him for epoch 1880·0, so that they may be comparable with those given in "Celestial Objects." The five years' procession will make so little difference that there need be no difficulty in identification:

(1) T Coronæ. 15h. 54m. 29s.: + 26° 15′ 36″. Authority: Gore's "Cat. of Known Var. Stars."

(2) Σ. 6 N. Taur. P. 18h. 6m. 16s.: + 6° 49′ 18″. Authority: H.'s "Gen. Cat. of Nebulæ."

(3) B.A.C. 6624 Lyræ. 19h. 14m. 57s.: + 40° 8·4′. Authority: Gore's "Cat. of Suspected Var. Stars."

(4) H. 5112 Sagittarii. 19h. 16m. 29s.: − 18° 14′. Authority: Vol. XL., R.A.S. "Memoirs."

(5) Bu. 142 Aquilæ. 19h. 21m. 30s.: − 12° 23′. Authority: Bu.'s "Third Cat. of New Double Stars."

(6) H. 1470 Cygni. 19h. 59m. 19s.: + 37° 59′. Authority: Vol. XL., R.A.S. "Memoirs."

(7) B.A.C. 7001 Cygni. 20h. 14m. 35s. + 38° 36·8′. Authority: Gore's "Cat. of Suspected Var. Stars."

(8) B.A.C. 7219 Cygni. 20h. 43m. 13s. + 45° 8′. Authority: Gore's "Cat. of Suspected Var. Stars."

(9) B. 658 Cassiopeiæ. 23h. 55m. 9s.: + 59° 41′ 12″. Authority: "Gore's Cat. of Known Var. Stars."

### Notes.

(1) D.M. + 26° 2765, 9·5 mag. Schmidt and Schönfeld, probable period 94 days.

(2) Planetary nebulæ: Small, but very bright, bore 400 well—like star out of focus. Fr., June 10, 1885.

(3) Lal. 36503 (6½m.): 7m. Harding: Pale orange, 7½m. Fr., May 10, 1885.

(4) Pretty 8m. triplet, like letter V, and all three white: 12 not seen. Fr., June 13, 1885.

(5) Lal. 36712. White: Exquisite pair, and not difficult. Fr., June 17, 1885.

(6) Lal. 38428. Pale orange, vivid blue, very beautiful. Fr., Jan. 6, 1885.

(7) There is an error of 10° in the decl. of this star, as given in Gore's catalogue. It was wrongly identified by me in 1877, the ruddy star being really B.A.C. 7008 (20h. 15m. 54s.: + 39° 1′ 32″), which is a little *n. f.* B.A.C. 7001. Both these stars are called 6 mag. in the B.A.C., and also by Groombridge, but they are certainly much smaller.

(8) About 40′ *s p.* 55 Cygni. Dull orange, 7-7½m., Fr. January 7, 1885. Gore 7m., May 21, 1883; below 7m., August 17, 1883.

(9) This is the variable U Cassiopeiæ. The estimates of mag. vary from 6 to 9: period unknown: It has a blue *comes*, similar to U Cygni.

May I now remind Mr. Ruthven that, in the last edition of "Celestial Objects," some 1,500 new objects were added to the sidereal portion, and most of these were taken from Struve. In his great work, the "Mensuræ Micrometricæ," containing above 3,000 double stars, the right ascensions are only given to tenths of a minute of time, and the declinations to single minutes of arc. The places of the brighter double stars might, of course, be found in various meridian catalogues; but, even then, it would look peculiar, to say the least of it, if part of the objects were given to seconds of R.A. and decl., whilst the remainder were only to the nearest minute of time and arc. Would not the compositor who set up the index of positions shower untold blessings on somebody's devoted head?

Surely, though, Mr. R. cannot be serious when he says, referring to objects in my lamented friend's work, that he cannot find them from the descriptions! I can emphatically assure him that I have never heard anyone else utter such a complaint. The nearest minute of arc is certainly sufficient in decl. for most people, including myself; and, as to the R A., the seconds would be perfectly useless without an accurate sidereal clock and transit instrument, or, in lieu of the latter, a time ball signal from the telegraph office. Such refinements are not within the reach of most amateurs, for whose benefit "Celestial Objects" was meant. I may tell Mr. R., further, that during the past nine or ten months I have examined over 2,000 sidereal objects, mostly from Webb, and the number of failures in identification is very, very small indeed.

**W. S. Franks.**

### STAR DISCS.

[24595.]—In letter 24538 I expressed the opinion (in opposition to Mr. Franks) that although high powers reduced the intrinsic brilliancy of star discs, the total quantity of light reaching the eye was the same as with lower powers. Further thought has modified my opinion, and I now conclude that any power that raises a disc reduces both the intrinsic brilliancy and the total amount of light. I will endeavour to state why I think so, for the purpose of benefiting by the criticism of Mr. Franks and others.

A star disc is not uniformly brilliant, but is brightest at the centre and fades gradually to the edges. Any cause that reduces the intrinsic brilliancy of disc, therefore, reduces the apparent size of that disc, because a portion of the circumference becomes too faint to impress the retina. Thus haze reduces star discs, and thus they are smaller with an unsilvered than a silvered mirror with equal magnifying power, and thus, also, a small star has a smaller disc than a large star. The theoretical disc is the same for all magnitudes: but the human eye requires a certain intensity of light to be visible at all, and with small stars this intensity only exists in the centre portions of the disc, and the outer annulus fades from view. The light is there, however, if the eye were sensitive enough to perceive it. Now, when we use a high power and enlarge a star disc, the intrinsic brilliancy of the whole disc is reduced, and a portion of the outer zone becomes too faint to impress the retina. The greater the enlargement the wider the zone which will fade. Now, this light in outer zone is entirely lost to us, and thus the total quantity of light impressing the retina is reduced. I hope not to be misunderstood: the same total quantity of light is present as before with a high power as with a low one; but the intensity of the marginal part of disc is so much reduced as to be no longer powerful enough to affect the human retina.

It follows from this that a very sensitive eye sees larger discs to small stars than a less sensitive one; that a high power reduces both intrinsic brilliancy and total light; that a high power gives smaller star discs than a lower power proportionately to the power, i.e., doubling the power does not quite double the diameter of disc; and therefore a high power will divide what a lower one cannot. How far the darkening of the sky which goes on side by side with increase of power tends to compensate for this loss of light depends very much upon the actual darkness of the sky at the time. It evidently does compensate to some extent.

Will Mr. Franks pardon me for asking how it is I am sneered at as wrong in saying the very things he says Mr. Dodge is right in.

**Edwin Holmes.**

### TELESCOPE POWERS.

[24596.]—In reference to this question, I may be allowed to remark that in No. 191 of the *Astronomische Nachrichten* there is a description of Mars, together with 24 sketches of the markings as drawn by Messrs. Beer and Mädler, at the opposition of 1830. The instrument employed was a 3in. o.g. by Fraunhofer of 45in. focus. The observers state that with a power below 185, but little detail could be made out, and that usually a single lens, magnifying upwards of 300 was employed with effect, owing to the excellent quality of their instrument. Occasionally a power of 400 was used; and on one night, when definition was specially fine, a power of 550 was brought into requisition. From this it appears that in certain instances at least 100 to the inch has been most successfully utilised.

With regard to the controversy on star discs, it does not need much optical knowledge to see that Messrs. Holmes and Dodge are correct in their deductions. Mr. Franks might have acknowledged his error in better form than he has done in letter 24565, p. 497.

**W. C. Rogers.**

August 7.

### CHEAP TELESCOPE STAND.

[24597.]—It has been remarked of my telescope stand, that the name of gimlet and string is so unphilosophical-instrument-like, as to be objectionable. My object has been to describe to our readers a cheap and efficient stand that can be made by anyone who can obtain the necessary tubing; but there is no necessity for either gimlet or string, or wooden arms to be used, as the necessary motion may be easily given to the telescope by screws, as in the usual altazimuth stand, thus, a fast and loose arm of wood or metal, carrying a screw, must be placed on the top of the upright socket in which the spindle turns, and another fast and loose arm carrying the nut of the screw must be placed on the upright spindle. These, when fast, will draw the telescope in altazimuth, and when loose will allow the telescope to be turned in any direction, so that the observer will always have the head of the screen handily placed for his use. A similar arrangement placed on the end of the sleeve, and on the end of the crosspiece, near the eyepiece of the telescope, will draw it to altazimuth. Thus all gimlets and string will be done away with, and the stand may be made as optical-instrument-like as desired.

The refracting telescope should have a diagonal reflector or prism at the eye end, so that the eyepiece may be always in the centre of motion, and the observer always facing the centre of the stand. With these alterations I believe the objection will be done away with. The telescope should be balanced without tendency to move in any way.

**Philip Vallance.**

### THE CASSEGRAIN.

[24598.]—In reply to "A. S. L." (letter 24456), it is very easy to find A B or A D when the foci of the mirrors and their separation are known. Thus, referring to Fig. 2, page 380, B D is the known separation, B C the given focus of the great mirror; hence (B D – B C) = C D = $u$, which is thus given, and by the formula—

$$\frac{1}{v} = \frac{1}{AD} = \frac{1}{f} - \frac{1}{u}\cdot$$

from which A D is readily found.

Two parabolic mirrors, placed at the sum of their focal distances apart, would certainly receive and reflect parallel rays without aberration; but would they, in this condition, be of any service as a telescopic arrangement?

**Orderic Vital.**

### NEW OPTICAL GLASS.

[24599.]—It will doubtless interest your practical optical readers to know that I have just received from the eminent glass makers, MM. Feil Père et Mantois, 30, Rue Lebrun, Paris, a specimen of what, I presume, is a new kind of optical flint glass. It is very heavy, and has a very pale yellow, or rather a very pale amber, tint. The specimen is cut from a plate ⅜in. thick, and is polished on one edge, is clear and transparent and free from any specks or air-bubbles. The label on it says "Flint, extra dense, No. 1738," and the density number is either "4 . 7" or "4 . F." I cannot make out what the latter (if correct) means, but 4·7 is more likely to be the true reading.

It is probable that this glass will be of much service to those engaged in spectroscopic and microscopic work; as, from its density, it must have a high refractive and dispersive power. I have no other particulars respecting this flint; but if any practical reader has received and worked any of it, I hope he will tell us what are its chief characteristics.

**Orderic Vital.**

### PYROLOGY—MANUFACTURE OF ALUMINIUM—CALCIUM.

[24600.]—Col. Ross is quite right in supposing that chemists desire him to examine the aqueous solution of his boric-acid bead for lime, though scarcely by the simple addition of oxalic acid to the liquid. An examination for lime by accepted methods, properly conducted, would be the way to prove his case to chemists, whom, Col. Ross complains, have an "animus" against him. I repeat that no one doubts the accuracy, so far as the small amounts of material permit, of Col. Ross's observation that he obtains a ball of four times the weight of the lime he uses, and that he does that repeatedly; but the complex molecular formula ($5CaO, 12B_2O_3$) corresponding to the experimental observation suggests to chemists that the composition of the ball requires rigid verification. This verification Col. Ross seems not to see the necessity for; but until it is performed chemists will be apt to consider his case "not proven."

Col. Ross conducts the operation in question in a small loop made at the end of a platinum wire. I suggested a platinum crucible as a suitable substitute for the platinum wire, and one which would allow of reasonably large quantities of materials being used. Col. Ross replies that "these reactions cannot be produced in that," that is, in a platinum crucible, though he does not state why a change in the form of the apparatus should alter the chemical reactions. However, if he prefers the "aluminium open furnace," by all means let him use it, and work on such a quantity of material as will satisfy chemists.

It is quite clear that if a balance be used which indicates $\frac{1}{10}$ of a milligramme, and that five milligrammes of lime be taken for an assay, the amount of lime used cannot be known within 2 per cent. On the other hand, if Col. Ross employed 5,000 milligrammes of lime, he would know the amount taken to within 0·002 per cent., and, assuming no error to arise from faulty manipulation or defects in the process, the accuracy of the determination would be correspondingly increased. Chemists ordinarily employ such amounts of material as can be readily manipulated, washed, &c., while allowing of sufficient accuracy in weighing. There is no balance in existence which would render the use of five milligrammes preferable to five grammes, on the score of diminished friction on the fulcrum.

The reference of Col. Ross to the delicacy of spectrum analysis is wholly beside the point. Spectrum analysis is a qualitative test, whereas the wet methods of chemical analysis aim at quantitative accuracy. Both are invaluable in their own way, as is the system of anhydrous analysis which Col. Ross has done so much to advance. But until Col. Ross can, with the blowpipe, determine accurately the lime present in a complex mineral, such as iron ore, his attempts to ridicule the only methods by which such a desideratum can be effected are, to say the least, out of place.

I am sorry I have trodden on the corns of "P. E. W." in my criticisms (p. 434) of his reply to query 56949 on the "Manufacture of Aluminium." But as his answer began with the words, "The following is Webster's process for the manufacture of aluminium," I thought it only right to state the details given did not refer to the preparation of the metal. This seemed the more necessary as a similar description of the preparation of alumina appears periodically in one journal or another, and is liable to mislead those who are unaware that Webster's process still necessitates the use of sodium as a reducing agent. According to "P. E. W." the product costs only about £100 per ton, instead of £1,000." Readers should understand that by the "product" must be meant alumina and not aluminium, the metal not having been appreciably cheapened by Webster's improvements in the preparation of the oxide. Certainly, from the reply of "P. E. W.," it might be supposed that the *metal* had been reduced in cost to one-tenth, especially as he immediately proceeds to describe the tensile strength and other properties of the metal.

This question of the cheap reduction of aluminium is highly interesting, and chemists are prepared at any moment to hear that the problem has been solved. Various patents have been taken out from time to time, in which a number of methods, more or less improbable and unscientific, are described. But what are we to say of the correspondent writing under the initials "F. W. G., Wolverhampton," who, on page 438, states that he obtained aluminium "in a simple and inexpensive way," and then calmly asks "if any person can inform him of the present price of aluminium." Now, if "F. W. G." and "P. E. W." will only put their heads together, the one producing pure and cheap alumina, and the other reducing it to aluminium in his simple and inexpensive way, there is no doubt that the metal will be much more largely used, and the proportion to be found in Webster's alloys will be greatly increased. As Mr. Grey reminds us, "E. G." wrote some time since that he had succeeded in reducing alumina by means of sugar, and *still* the metal is expensive.

"F. W. G.," who, on page 481, gives his name more fully, has not only reduced aluminium simply and inexpensively, but has also obtained calcium from lime by the same process. His description of calcium as a beautiful white metal which will not odidise is a most interesting and novel statement, as calcium has hitherto been obtained (as a chemical curiosity) as a yellow metal, oxidising with facility in moist air, and violently decomposing water. But is it not a pity that Mr. F. W. Gerhard should have kept this information to himself, when, by publishing it in some scientific journal and sending specimens of the metal (say, of a few pounds in weight) to the Chemical and Royal Societies, he would have made himself the scientific lion of the season? He has another chance in the British Association, which will meet at Aberdeen next month. If circumstances prevent him from personally attending and exhibiting his calcium and calcium alloys, I shall be very proud and happy to do it for him, and will take care that he receives full credit for his interesting and valuable discovery. There is no occasion for him to make known the process by which he achieved success, and by which he will, no doubt, acquire riches as well as fame. But why, oh why, did Mr. Gerhard first announce his discovery under mere initials, and in a reply to a question on another subject? Here is a discovery that some of us would have given our ears to have made, and the modest Mr. Gerhard appears to think it of "no consequence." I hope it is not another disappointment for us, like the manufacture of diamonds, the production of quinine, and the decomposition of chlorine.

Sheffield. **Alfred H. Allen.**

### CAN ALUMINIUM BE EXTRACTED CHEAPLY?

[24601.]—I AM afraid that letter 24585, page 501, does not throw much light upon the above question, which I have copied therefrom. The difficulty lies, not in the production of alumina, but in the extraction of the metal from its oxide after the latter is obtained; even were alumina got free of cost, it would, I believe, not very materially lessen the price of aluminium, for the cost of reducing the chloride of sodium is much greater than the cost of the two preceding processes—i.e., the preparation of alumina from bauxite, and conversion of it into the double chloride of aluminium and sodium. The great reducing agent in metallurgical work is C, or CO, and unfortunately the reduction of alumina by either of these bodies is absolutely impossible, according to the principles of the conservation of energy. I pointed this out some time ago, in reply to a correspondent, "A. E. S.," who said he had reduced $Al_2O_3$ by means of sugar; his reply was not altogether respectful to the conservation of energy; but I have not seen cheap aluminium yet. Mr. Allen is well able to hold his own in his controversy with Colonel Ross as to the borate of lime beads, and I do not intend to interfere; but I would like to say that I entirely agree with the Sheffield gentleman that so far the Colonel has not proved anything as to his beads.

**Wm. John Grey, F.C.S.,**
Newcastle-on-Tyne. Analytical Chemist.

### GRAY'S WATER MICROSCOPES.

[24602.]—UNDER the heading "A Pocket Field Microscope" (24586), a form of microscope is described for utilising lenses composed of drops of water.

Permit me to remark that the microscope in question is an inferior form of the "Water Microscope" I invented some 200 years ago, and which I communicated to the Royal Society near that date.

The inferiority consists in the practically impossible condition that with a magnifying power of 100 diameters the hand will be steady enough to focus by merely pressing together two blades of bent metal connected as a V. Such an arrangement is worthless. My plan provided a thumbscrew for adjusting the focus.

Nearly every textbook of the microscope in English, French, or German, published since that date, refers to my water microscopes.

In the ENGLISH MECHANIC of June 5, p. 299, my water microscopes were described with commendation—a commendation that was gratifying to me in spite of my years.

**The Ghost of Stephen Gray.**

### FLOWER-POTS.

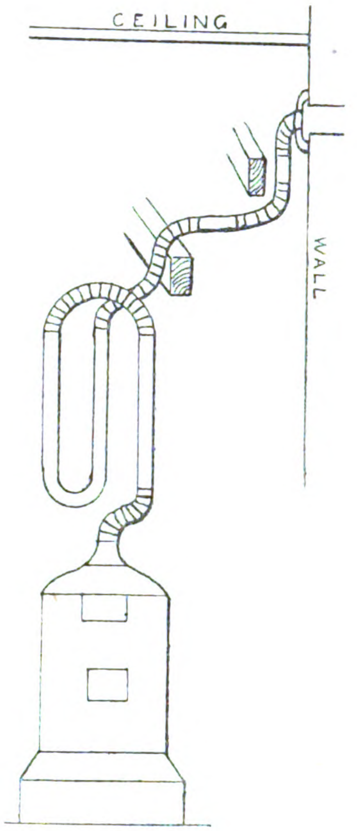
[24603.]—IN reply to "Conservator," letter 24553, four years ago I had a lean-to greenhouse 18ft. by 7ft. erected; it faces the east. When I selected plants for it at the nursery, I asked if glazed pots would be suitable for growing the flowers in. I was told they were not suitable, and that if I wished to have fine growing flowers, I must have the usual unglazed pots. Although I had never seen the glazed pots used, I was sceptical of the universal opinion expressed by the florist, so resolved to have a trial of the glazed pots. I bought about 70 them assorted, 5in., 6in., and 7in., and had the flowers put into them in the usual way. About a year after this a gardener happened to call, and I showed him my greenhouse, and he was surprised at the healthy green appearance of the plants; in fact, they were far healthier-looking than his own. I have never failed to grow the usual greenhouse plants in them; quite the contrary, they grow well and keep an appearance to be seen in very few greenhouses as far as healthy look is concerned. There is one drawback, however, not with the pots, but the exposure of the house (east). It tends to draw the flowers too much.

I do not know anything about the scientific views on the subject wished by "Conservator"; but from practical experience I may say all the difference I can find is that the glazed pots require much less water, and probably a little better attention to prevent overwatering. That is all I can make out, and I have had four years' trial of them. They always look nice on the shelves, and never get green. I believe if some potter was taking it up and bringing out something unique, pretty, and cheap, he would have a large sale for them.

**M. C. J.**

### A CURIOUS STOVE.

[24604.]—IN an old house on the hills near to Zugg, in Switzerland, I found a bedroom warmed by a stove of which the pipe was convoluted in the strange fashion indicated in the inclosed rough sketch, and the pipe was without support, running clear of, and over the lower, and under the upper, of the beams which are indicated. The segments seemed to fit and "bite" by merely twisting them together.



The bends of the pipe were all made in the manner of what we know as the lobster-back cowl, used upon our chimneys. A workman took this apparatus down, and put it up again in less than two hours, while I was there, and no solder nor rivet was used in doing so. Can any reader kindly tell me if a similar arrangement of 3in. 3½in., and 4in. stove pipe is known in England? Personal inquiry of the attendants at the stove departments of both the Healtheries and the Inventions has failed. **Wm. Lane Sear.**

### DAY OF THE MONTH CLOCKS.

[24605.]—I THINK letter 24559 on this subject, with a mysterious French signature, is right; but I have no means here of looking further into the construction of such clocks. Perhaps the writer can give a drawing and description of "the Ithaca construction," which he mentions.

He is wrong, however, in saying that I attributed to Americans the conversion of what certainly used to be written "bunkum," and to mean bluster, into "buncombe," meaning (he says) flowery language for the captivation of a place of that name. I attributed it to Englishmen who are familiar with the name of the Duncombe family, though probably Americans are not. "Bunkum" is a word that somehow suggests its own meaning, which "buncombe" certainly does not in England.

**Edm. Beckett.**
Batch Wood, St. Alban's, Aug. 6,

### COLLIERY EXPLOSIONS.

[24606.]—IN your issue of the 10th of July I notice a letter (24447) from Col. Shakespeare, in which certain suggestions are made under the belief that if carried out they would tend to prevent such occurrences in the future. The desire of your correspondent to benefit the thousands who are interested, and in many cases unable to help themselves, deserves some attention from those who, by experience, are well versed in this important question. As a mining engineer, it will not be difficult for me to show that Col. Shakespear's suggestions are practically of little value for the purpose intended; although from the lack of particulars as to the exact method of carrying out the ideas of your correspondent, I shall only be able to deal with what is really stated. It is quite true that a fall of the barometer to the extent of ½in. reduces the atmospheric pressure 35lb. on the square foot; but the further statement that the action of a furnace or fan reduces the pressure another 35lb. is scarcely applicable to ordinarily managed mines. Col. Shakespeare says a ton of hewn coal is capable of giving off 10,350 cubic feet of carburetted hydrogen. This, under some circumstances, may be so, but in the mine I question whether anything to prove this statement has ever occurred. Your correspondent further states that a blower is known to be under pressure of 30 atmospheres, which being more than 400lb. per square inch, I would ask What use would the maintenance of the ordinary atmospheric pressure of 14lb. be to such an enormous pressure as stated above? And further, Col. Shakespear must know that a face of coal is constantly generating gas which, if kept back by a greater pressure, would in a very short time in itself overcome that increased pressure, and gas would flow as freely from the coal, and in such quantities, as from time to time were generated, just as if no increased pressure had been supplied; whilst on the slightest reduction of the artificially increased atmospheric pressure, the pent-up gas in the seam would be liberated in greater and more dangerous quantities than under ordinary circumstances could occur. To attempt to prevent the natural escape of firedamp is always dangerous; escapes both large and small will always take place, and the only way to prevent or minimise colliery explosions is by enforcing a good uniform discipline which will provide for these occurrences by never underrating or treating too lightly the risks which those having had experience in fiery mines know sadly too much of. **G. Worlands.**

Aug. 3.

### MAGNIFYING POWER OF REFLECTORS.

[24607.]—WILL you allow me, as an old subscriber, to say a word about high magnification of telescopes. W. P. Dodge (letter 24545) writes as if a 12in. mirror will bear 600; and again, he says his 6½in. raises a disc with 300 and 600. Does this apply to bright stars? I have an 8½in. mirror by one of our first makers, but I cannot obtain a clear disc with 200. I have a friend with an 8½in. by the same maker and he cannot do it. I have had several letters from him in which he complains that Arcturus is nothing except with a very low power. He has been staying with me for a short time, that we might compare notes together. My 8½in. performs exactly as his own. With 53 on Arcturus I get a clear and beautiful disc. Raised to 130, the disc is surrounded with rays like the small diagrams that represent first-magnitude stars on maps. With 200 it is a smudge, like a nebula with intensely bright points. A 5in. achromatic by Grubb will show distinctly a disc and diffraction rings when using the higher powers. But with the reflector neither disc nor rings are visible. May I ask if any other observers have been thus troubled when looking at first-magnitude stars. I had the same annoyance a few years since with a 6½in. mirror, and I know others with the same experience.

The question arises, Are mirrors a failure on bright stars? Can anyone tell us how the giant mirrors perform? Are they used only on minute stars? **T. H. Browne.**

### WATER-WASTE PREVENTERS.

[24608.]—"MONTMARTRE" (letter 26522) has found a common defect in water-waste preventers. I have found those in the market so trumpery, that I have special patterns made to supply what I consider a great want—namely, a good, strong, useful water-waste preventer. I should expect to find "Montmartre's" trouble lay in the pulling of chain and lifting the lever so high, and ball with it, that it cuts the rubber through before coming to the stop. Care should be taken in fitting that the stop should stop the pull, not the rubber and seating of ball-cock, which is usually the case. **E. Knight.**

### SAFETY BICYCLES.

[24609.]—THE opinion of the cyclist portion of your correspondents on the above subject would be very interesting and instructive to others besides myself. The geared bicycles have been in the market about two years now, so that there has been time to test the virtues of the various patterns. Before I rode one of these machines, I had big expectations of the speed I could be able to fly over the country; but actual experience has, up to the present, shown those expectations to be hardly fulfilled.

I ride a "Kelsey," 36in. wheel, geared to 54in.

I find it a great strain on the wrists to steer, and cannot get up a speed on level road above 9 miles per hour without undue exertion; then, not being of a suicidal tendency, I have had to dismount at every patch of fresh-metalled road, and if I fall at all it is over the handles, which, with these safeties, is supposed to be impossible under ordinary circumstances. I have to walk up hills which with a tricycle (Greyhound) I have ridden up with comparative ease. Any roughness or inequality in the road is painfully forced on my attention by being jolted almost out of the saddle, and I could almost plant a tree in the dust deposited on my trousers after a five-mile ride. There is no doubt that these geared bicycles make splendid track machines; but a 36in. wheel is too small to roll over the impediments in a rough road. The difficulty of driving may be that it is geared too high. Am I alone in these experiences? I should very much like to know. (P)

## THE OTTO BICYCLE.

[24610.]—In answering "A South Australian Bicyclist" I do not propose to say anything about the merits of this machine, as they are now pretty generally recognised, but shall give the result of the last year's experience as to the most desirable size, &c.

I used to speak in favour of the high 56in. wheels as being on the whole preferable to smaller wheels, though for mere pace on a good road the smaller size, geared up, was found best. For all-round work most riders preferred the large wheels.

Now that the best riders of the Otto have adopted the elastic spokes, there is a change. A 50in. or a 52in. elastic wheel gives far more than all the comfort of the ordinary 56in. wheel, while it has in other respects all the advantage of a light, small wheel; and so each rider who makes the change from 56in. straight spokes to 52in. elastic spokes finds an increase in his average speed of from one to two miles an hour.

I have now ridden my elastic wheels over 2,800 miles, which is enough to show that the spokes retain their form. As to the strength of these wheels, I have treated them more severely than I should have dared with the old rigid wheels.

I still use rubber-lined bands; but flax-lined bands are now supplied, and give, I believe, satisfaction. I find the rubber-lined bands behave perfectly in the hottest and dustiest weather, and in the wet and snow of winter; but some riders found them give trouble, and so the flax-lined bands have become general. It would be quite unnecessary for "A South Australian Bicyclist" to have more than one, or at most two, pair of spare bands. **C. V. Boys.**

[24611.]—In reply to "A South Australian Bicyclist" (letter 24571), I have much pleasure in saying that my enthusiasm for the Otto, and delight at that method of conveyance, are unabated.

The machine wants learning, and is well worth it. For my own part, after a year's experience, I am learning it yet, in the sense of the illustration given in your pages a few months ago by a skilful rider. He explained, with reference to an inquiry as to simultaneous stopping and turning, that proficiency on the Otto is akin to proficiency on the piano; and where one performer can only manage straightforward tunes and simple passages, another can emulate the variations of Mr. C. Hallé.

Unfortunately the Otto is not so widely known as it deserves to be. It is strange that the makers do not send an itinerant representative from town to town, who could introduce the machine to the cyclists of each locality. Perhaps South Australia is rather too distant for missionary enterprise of this character: but your correspondent would find the published "Hints on Riding" amply sufficient for his guidance. **Antares.**

## ON THE CONSTRUCTION OF A WHEATSTONE'S BRIDGE.

[24612.]—A perfect Wheatstone's bridge is a piece of apparatus which is very expensive to buy, and in its usual form not very easy to make. Below I give the necessary description of and directions for constructing a form of bridge which has given very good results in my hands.

The first step is to make a box to contain the coils, the bottom and sides of which may be made of deal, stained black and well varnished or French polished. The top, however, which is to hold the necessary apparatus for manipulating the coils, must be of hard wood, such as oak or mahogany, well seasoned, and varnished on top; the whole, when complete, to be similar to Fig. 1.

The most useful set of coils to use are, for the variable arm: 1, 2, 3, 4, 10, 20, 30, 40, 100, 200, 300, and 400 ohms; and for the others, 10 and 100 each. With this set any resistance between ·1 and 4,000 ohms may be accurately measured. We have now to make these coils. For this purpose we shall require a differential galvanometer and a 1-ohm coil. (I shall be glad to send anyone desirous of constructing a bridge a 1-ohm coil.) By means of the coil and galvanometer, another 1-ohm must be taken, and with the two coils coupled together a 2-ohm must be measured, then from the 1 and 2 ohms a 3-ohm is obtained, and on on. It is obvious that by this means coils of any value may be taken. They are made of German-silver wire, No. 30, for the small coils, and No. 38 or 40 B.W.G. for the larger ones. Each coil is next wound on a core of paraffined tissue paper, each layer of wire when completed being dipped in melted paraffin, when the whole of the wire is wound on except the two ends, which are to be left free. It is placed inside a small wooden tube (which may be obtained from any wood turned for a small sum); the coils now have the appearance of Fig. 2, and will be ready for mounting in the box.

FIG. 1.

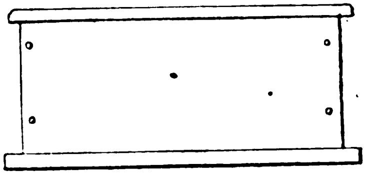


FIG. 2.

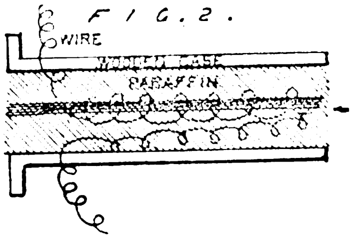

The box-lid, however, still requires the necessary apparatus for throwing the coils in and out of circuit. For this purpose cut out of sheet brass (about the thickness of a postcard) a number of pieces equal to the number of coils used—2, similar to Fig. 3; also 4 pieces as Figs. 4, and 2 of Fig. 5.

FIG. 3.

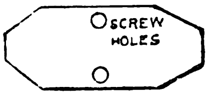

FIG. 4.

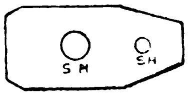

Fig. 6 will indicate the respective positions of the different shapes. To the middle point of one side of each of these brasses, solder a thick copper wire, about 3in. long; next, bore holes in the wooden top in such place that the brasses may be arranged as in Fig. 6, whilst the wires project through to the other side. Procure 18 binding screws, as Fig. 7, and screw them up tightly at *a*, so that they will not come unscrewed.

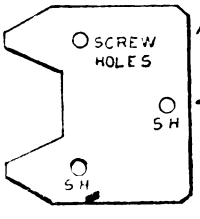

FIG. 5.

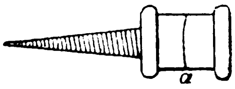

FIG. 7.

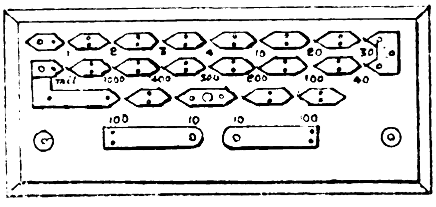
FIG. 6.



Between every two brasses on the box-lid, drill a hole, and place therein a binding screw, so that the shank shall not touch either of them; Fig. 8 will explain itself.

When the binding-screw is screwed fully down, the flange makes contact between the two brasses, and throws the coil beneath it out of circuit, and *vice-versâ*. The coils may now be placed in position, which is done by means of glue and screws, the ends of the coils being soldered to the copper wires projecting from the brasses (as seen in Fig. 8). The connections are now to be made by soldering thick copper wires underneath the lid of box. Connect A to K, H to L, M to C, B to E, F to $G^1$, $G^2$ to D (Fig. 9).

FIG. 8.

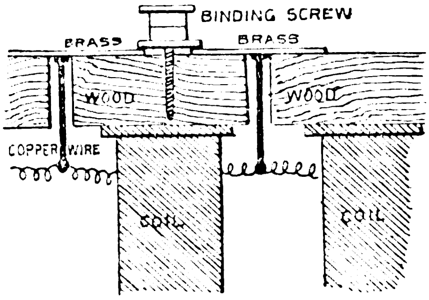


FIG. 9

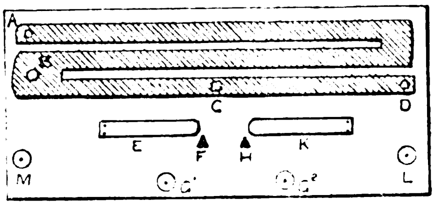

The galvanometer is connected up to $G^1$ and $G^2$. The battery terminals to M and L, whilst the resistance to be measured is placed between A and D. E and K are contact springs, F and H being the buttons underneath upon which they strike to make contact. **Fred Loundes.**

## SIGNAL RETURNS.

[24613.]—I am rather astonished that "Coral," in last week's number (letter 24576), should ask for an explanation of these returns, because they are as clear as they can be.

A junction between "passenger lines" means exactly what it states. Junctions between a passenger line and a goods line also is perfectly plain. "Any siding" means, of course, what it says, *any* siding, passenger or goods. "Safety-points" refer to "Safety points required to prevent trains running out on main line," not to runaway catch points. A "loop line" has two junctions, one at each end; an ordinary double line junction is one junction. The Return *re* Signals gives all that is wanted, so I don't see why "Coral" wishes for more. **Signal Post.**

## FAILURES OF BRAKES.

[24614.]—Would "Midland" or other reader be so good as to explain the cause of that long "72 minutes delay" mentioned last week? Was it the ball-valve sticking, or was it dirt in the leak hole? The leak hole brake did not cause such delays as the above, and the change seems a doubtful improvement.

On the 25th July, 1885, there was a series of delays to a special of volunteers returning from Portsmouth to Derby. The train was made up of L. and S.W. carriages with the ball valve brake. The hose pipe opened and admitted air, and the brake went on and caused delays as the vacuum brake would not come off, and at Bedford they had to take a carriage out of the train and move the passengers.

There was another vacuum failure on the 6th inst. A hose pipe on the 11 noon Manchester to St. Pancras broke and destroyed the brake. The strange thing was that when the vacuum automatic brake failed it did not stop the train. Perhaps "Meteor" or some of "Ours" would say where the automatic action went to? **Loco.**

## THE PENISTONE ACCIDENT.

[24615.]—In reply to your correspondent "Traveller," p. 500, last week, I regard the failure of justice in the action brought by Mrs. Woodhead against the Manchester, Sheffield, and Lincolnshire Railway Company as a very serious matter, both for the widow, the travelling public, and the railway servants. The company employed Smith's vacuum brake, which is well known, and admitted to be inefficient and useless in case of accident; it has persistently disregarded the conditions of the Board of Trade laid down as long ago as August, 1877. It was conclusively proved in evidence that the absence of a quickly-acting automatic brake was the cause of the fearful loss of life. It therefore follows that the company neglected its duty within the meaning of Lord Campbell's Act of 1846. I was in court throughout the hearing of the plaintiff's case, and after the evidence given by Major Marindin and other witnesses, I am perfectly at a loss to understand upon what grounds any jury could return a verdict in favour of the company.

Attention may here be directed to a comparison of the Penistone and Downton accidents; in both instances the trains ran off the line, down the embankment, and persons were killed in consequence of there being no efficient brakes.

In the former case the jury awarded no damages, and appeared to consider there was no "neglect." In the latter instance a jury concluded that there was serious neglect, and very properly gave fair damages accordingly.

The result of the Penistone case may be regarded in a serious light not only with reference to this accident itself, but as a precedent to the future. In point of fact, it simply means that companies can run their trains as they choose, may kill passengers at pleasure, and cannot be made to pay for the results of their own "neglect."

**Clement E. Stretton, C.E.**

Leicester, August 8th.

### THE PENISTONE ACCIDENT—WOODHEAD v. M.S. & L. RAILWAY COMPANY.

[24616.]—"Traveller" (in his letter 24577, page 500) asks for the opinion of railway correspondents on the above, and as to what negligence is. From his remarks offered, he is evidently one of those who "Damnant quod non intelligunt."

In the first place, his statement as to "persons being killed in consequence of neglect of 'company' to provide proper brakes" is entirely incorrect, as a slight review of the facts will show.

The accident was caused primarily by the breaking through of the web of the crank-axle. This caused the connecting-rod to break, which plunged into the ground, and tore up the check rail and the line generally, the tender leaving the metals. The next coach to the engine, having no rail to run upon, naturally continued in a straight line, and as the rails here took a curve the couplings (regulation pattern and strength) broke, and the train was precipitated down an embankment, the engine keeping to the rails.

The question now resolves itself into numerous points, the principal, however, being as to whether the company had employed sufficient care in providing and examining the crank-axle, and whether they had in use an efficient brake, or whether, under the circumstances, a brake would have been of any avail at all.

I may here explain that negligence is "want of attention in exercising due care, skill, and foresight in everything that concerns the safety of passengers."

Let us now examine the facts elicited at the trial. It was proved to the satisfaction of the Judge and a more than usually competent jury (a number of them being engineers) that the "big end" had been taken off only a fortnight previously, and a careful examination made, and no flaw detected (the spot where the flaw occurred was covered by the big end, and therefore it could not have been seen in the usual daily examination); that it was not the custom or practice of *any* railway company to take the big end off more than once a month (the engineer of the Great Western stated that on that line it was only taken off once in two or three months). That the flaw was an internal one, which grew outwardly, and most probably was not visible until the very moment the accident occurred. So much for the crank axle.

With regard to the brake, the plaintiff's own witness, Major Marindin, stated that, in his opinion, no brake in the world could have prevented the train from running over the embankment. This being so, the probability of any other brake than the one used lessening the mortality is merely conjecture, and I endorse the very general opinion that an automatic brake might, by prematurely locking the wheels, have caused the carriages to tumble topsy-turvy, instead of running down, and thus made the result even more deplorable than it was.

A small point, I may mention, was raised as to the position of a horse box in the train, it being the first carriage after the engine; but although Major Marindin said the proper place for it was at the end of the train, still, in his opinion, he said that would not have in any way avoided the accident or decreased its results.

The company, therefore, having provided the best crank axle procurable (the cost of a locomotive crank axle, "Traveller" may be surprised to learn, is usually about £125), and examined it at intervals, which, according to all railway engineers, exhibited sufficient due care, skill, and forethought, and the brake not in any way, according to the plaintiff's principal witness, affecting the accident, why, I should like to ask, should the company be liable?

I am sure that with the above circumstances before him "Traveller" will have no occasion to again ask, "Justice! where art thou?"

**Vera pro Gratiis.**

Manchester, 10th August.

---

[24617.]—I am a strong advocate for automatic brakes; but I cannot arrive at the conclusion which your correspondent "Traveller" does in last week's issue, that the verdict in the Penistone case was wrong, and that "24 persons [were] killed and 62 injured through neglect to have a proper brake." I think the verdict was quite right, and further believe that no automatic brake in this case would have avoided the loss of life. Automatic brakes are of the utmost use in many cases; but there are many cases where they will not prevent a calamity, and I quite think, having heard the whole case, that the Penistone disaster was one. It was generally admitted that the train was running about 50 miles per hour down an incline of 1 in 124, and on a 40-chain radius. The axle of the engine broke west of the signal-box, and by some extraordinary means tore up the check rail opposite the signal-box, which was found imbedded in the bottom of the tender. This rail injured the vacuum appliances under the tender, and no doubt the hose coupling was then broken. The signal-box is 102 yards from where the left rail was broken up, and the carriages ran off at a tangent down the embankment. An automatic brake takes about two seconds before it comes into full operation. Fifty miles an hour is practically 25 yards a second, so assuming that the train had been fitted with an automatic brake, and that the hose pipe was broken when the rail was torn up at the signal box, the train would have run 50 yards of the 102 before it was full on. Now the question is, Would any brake have pulled the train up in the remaining 52 yards, or, at any rate, have slackened the speed to any considerable extent, and so have averted the loss of life? I do not think it would, and rather think the silence of some of your esteemed contributors on railway matters know it would not. In Captain Galton's trials with an automatic brake on the L. and T. Railway, a similar train to this on a like gradient, was reduced from 45 to 37 miles in 102 yards, and in some experiments on the Midland made some time ago, a similar train to the Penistone train, on the level, was reduced in speed in 102 yards from 50 miles an hour to 44½, and, in another case, to 44. If, therefore, the Midland train travelling at 50 miles an hour on the level could only be reduced to 44 miles in 102 yards, how could the Penistone train, going at 50 miles an hour on a falling gradient, though on a 40-chain radius, be reduced much below 44 miles an hour? The first carriage, in which all the loss of life took place, must have gone over the embankment while the speed was very great, and in the 102 yards available, I do not think any known brake would have prevented it. The question is an all-important one, and I think, and hope, the day is not far distant when automatic brakes will be in general use; but, as an old subscriber, and feeling that the verdict, under the circumstances, was right, I cannot let "Traveller's" letter go unanswered.

Manchester, Aug. 10. **W. G.**

### MIDLAND ENGINES.

[24618.]—"Kappa" says (p. 476) that the new M.R. engines "are, or will be, amongst the finest in the kingdom."

Would he explain his reason for thinking so, and is he aware of the number of failures and breakdowns with these engines? No. 1675 alone has failed, and had to give up the Scotch expresses on many occasions, and only so lately as the 6th inst. the 10 a.m. Nottingham express from London had to make a special stop to put off engine 1674, hot and broken down. With all these failures on record, I can't agree with "Kappa"; but quite agree with those who have said the 800 class are the finest on the Midland. **Express.**

### HYDRAULIC RAMS.

[24619.]—As information respecting rams seems to be wanted, it may not be out of place to give particulars of two or three which are at work under what I consider extra low falls.

One has a fall of 3ft. 9in. from head to tail; water has a rise to cistern on top of house of about 100ft. This ram delivers about 1,000 gallons in 24 hours, and has a 4in. drive pipe.

No. 2 ram has a fall of 2ft. 8in., except when the water is stopped back for watering meadows; then it works under water with less fall. This ram, a 2½in., delivers, with the 2ft. 8in. fall, between 900 and 1,000 gallons daily to a height of 36ft. When the water was first let into this machine, the valve would not rise, but let the water continually run to waste through it. I had another valve made; you would suppose a lighter one, but I had a heavier one made, with less waterway through it, and it has answered well since.

The third ram I was sent for last week to repair, and once before soon after it was fixed. This ram has a 1¼ drive pipe, and was put in some two and a half years back by a London firm; it has a fall of about 3ft., and a rise to cistern of about 30ft. This ram is fixed in such a way that it is a wonder it works at all. When I left it, it would only rise the water to the ground level at house about 20ft., it would not lift to the cistern about 10ft. higher. It is fixed about ⅜in. out of level, in a pit close to dam, with 12ft. of horizontal drive pipe laid 1ft. 6in. under water, with a bend and elbow before entering ram. If this ram were properly fixed, with sufficient drive pipe, I am satisfied it would do double what it has done. **E. Knight.**

### SULPHATE OF SODA IN DANIELL'S BATTERY.

[24620.]—It has been suggested to me that mention of the following fact, in which I have very likely been anticipated, but which I described in the *School Guardian* of last Saturday, might not be without interest for the readers of the English Mechanic.

I have been in the habit of using Daniell's cell for the electric bell, dispensing with the porous-pot and the dilute acid, and leaving the zinc as well as the copper in immediate contact with the copper sulphate. I may well be asked how I prevented the deposition of copper upon the zinc rod through local action where the circuit was broken. I suppose that the difficulty would have arisen earlier had I not filled up the cell with sawdust and wrapped the zinc in paper or cloth. With this arrangement, however (which I had adopted for entirely different reasons), the gradual deposition of zinc sulphate upon the rod protected it, to a great extent, from the polarisation, which could not be entirely prevented. Curiously enough, even the moist cloth or brown paper seemed to act as a conducting plate, and received a considerable deposit of copper when I omitted the sawdust.

Considering, however, that the dilute sulphuric acid which, in the usual arrangement of Daniell's cell, is in contact with the zinc, serves the purpose of preventing permanent polarisation through the deposit of copper, and that this is the only purpose which it does serve, it occurred to me that I would recur to the porous pot and the two-fluid system; but would substitute a strong solution of sulphate of soda for sulphuric acid. I at once found, as I expected, that whether I used sulphate of soda or acid (the latter was diluted in the proportion of 1 to 12 by measure—say, 1 to 8 by weight), the needle of the tangent galvanometer assumed and retained exactly the same position; but that whilst the acid corroded the zinc, and produced a large development of hydrogen bubbles (owing, perhaps, in part to imperfect amalgamation), the neutral sulphate was perfectly harmless, and might be left in contact with the zinc, after the circuit was broken, as long as I pleased. Of course, the principle is the same as that of the Leclanché cell, in which the sal-ammoniac is perfectly passive until the circuit is completed.

It is quite clear that the sulphuric acid ordinarily used in Daniell's cell can furnish no energy to the combination, because, as fast as it is decomposed by the zinc, it is recomposed at the expense of the sulphate of copper. It simply transmits, so to speak, the molecules of $SO_3$ from the outer cell to the zinc, and so far as it does more than this it is mischievous. **Abner E. Brown.**

Wadenhoe, Oundle, Aug. 10.

### HIGH CHIMNEYS.

[24621.]—In your impression for July 31st you say "the highest chimney in England is said to be Messrs. Muspratt's chemical works," &c. This chimney does not exist, it was blown down with gunpowder about nine years ago.

The highest existing chimney-shaft in England now is that of Messrs. Dobson and Barlow, Kay-street Machine Works, Bolton, Lancashire; it is 367ft. 6in. high from ground line, and measures 14ft. on each side of octagon at base, and is 44ft. girth at top. In its construction there were used 800,000 bricks and 120 tons of stonework, and cost £3,000.

I wish correspondents would give references as to where they get the information from which they are answering questions: it would add much to the value of their contributions.

My authority for the foregoing correction is "Bancroft on Tall Chimney Construction," pages 40–41, new edition.

**James Walters.**

20, Traffic-street, Derby.

### A NEW FIRE-ALARM.

[24622.]—In the English Mechanic of Aug. 7 you illustrate what is called a "New Fire-Alarm," said to be invented by a Mr. Pritchett. Will you kindly allow me to state that this is a mistake? It is exactly the same as one invented by me in the year 1866, an improved form of which I patented in 1870. For this instrument I obtained the highest and, in fact, the only award given for an electric thermometer at the International Exhibition, South Kensington, in the year 1871. (See Official Catalogue.) This was not only a fire-alarm, but also intended for gardeners to record in their dwellings the temperature of their plant houses; hence it was specially noticed in the horticultural journals at that time—see *The Gardeners' Chronicle* of Nov. 5, 1870, and *Gardener's Magazine* of Nov. 26, 1870, where a full description, with illustration, will be found. It was also noticed in most of the scientific papers at that period as well.

A very fine account of it appeared in a German paper, *Der Bazar*, Sept. 11. Unlike the description you give, they carefully excluded my name in connection with it. They gave even an exact copy of the engravings which appeared in the English papers, except that they removed the words "Rothnie's patent," which was on all English copies.

**Geo. Rothnie.**

## RIFLE SHOOTING.

[24623.]—I CANNOT quite agree with "Invicta," letter 24587, p. 502, as to the utility of the various contrivances at present in vogue for obtaining rifle practice (?) without rifle ranges; for it must be remembered that it is only one part of shooting to be able to hold a rifle steadily and pull without jerk. Certainly it is a very important part, but even after it has been mastered there remains very much to be learnt. The absence of recoil in the said contrivances is against their usefulness as a means of education in shooting, for it is quite possible that a man would pull steadily with them who would prove the very reverse of steady when subjected to the recoil of the Martini-Henry in actual practice.

It must be admitted, on the other hand, that their use in Volunteer corps would probably do something to get rid of the present system of class-firing, in which a recruit goes to the range, loads a rifle, points it in the general direction of a target, pulls the trigger, and *opens his eyes* to see what has happened. And when a man has got through this performance a certain number of times (60), *even though he never hit the target* at all, he is an "efficient" Volunteer. The contrivances for converting Martini-Henry rifles into pop-guns do not enable a man to learn anything as to allowance for wind, or as to change of elevation on account of variation in light; and until these are mastered a man cannot shoot. Many a novice wonders why he is missing the target when he is aiming placidly straight at the bull's-eye, while a 6ft. wind is blowing, and the light changing for every shot. I well remember some years ago asking a comrade who had just got up, after finishing with four bulls, where he had been aiming. He replied that he had not aimed twice at the same spot. I thought then he was unwilling to help me, but I know now he was speaking the truth. It is much to be regretted that shooting is so little taken to even amongst the Volunteers themselves. Perhaps one reason is that it is too quiet to suit the average young man, who wants something more energetic as an outdoor amusement than lying down and holding his breath while he aims at a mark nearly half a mile away. The fact that a rifle meeting is not so interesting a spectacle as compared with a cricket match or bicycle meet is doubtless another reason. There is usually not much for visitors to see, and an outsider scarcely knows, or has means of knowing, whether he is watching a pair of crack marksmen contending for the bronze medal of their county, or a couple of novices who have to do all they know to avoid missing outright. On the other hand, the amusement is entirely free from cruelty in any form, and a man may listen to the sharp splash of the bullet on the target at 200 yards, or the faint tap which is heard at the long ranges, with a pleasure unalloyed by the knowledge that a living thing is quivering under the blow. Again, accidents are *very* rare, and when an accident does happen it is almost invariably to a marker, and not to a competitor. Last, but by no means least, the science of rifle shooting has not been prostituted to betting; a friendly wager between comrades is frequent enough, but that nuisance of the nineteenth century—the professional betting man—has no scope for his nefarious practices at Wimbledon, Altcar, or Morpeth.

**Wm. John Grey, F.C.S.,**
Sergt. 5th Durham,
Hon. Sec. Derwent Rifle Club.

Newcastle-on-Tyne.

[24624.]—IN the interest of all true lovers of good shooting, I hasten to dissuade readers of the "E. M." from following "Invicta's" vicious advice. The abortive attempt which has been made to convert the regulation rifle into a small bore will ruin the prospects of our embryo crack shots, if they persist in practising with this wretched arrangement. Now that firing at moving objects has become an important part of the army rifle drill, it is more than ever necessary to accustom ourselves exactly to the weight of the weapon we use; and the man who cannot distinguish a difference of half a pound in the rifle is not safe to half a yard on the target. No. 1 bulleted caps cannot by any stretch of imagination be considered practice for the Henri-Martini cartridge; and as for the absurd close-quarter paper targets, they are, in my opinion, simply ridiculous.

**Bacchus.**

## BI.'S AND TRI.'S—SPRINGS—CLUTCH GEAR—BALL BEARINGS.

[24625.]—IF "South Australian" (24571, p. 498) were in England, he would see that the two things most remarkable about riders of the Otto are their scarcity and their apparent caution. Though the machine has been out for some years, they are still so rare that they are stared at as they pass. Many tricycles that have not been out half the time, or near it, are much more numerous, and I have rarely seen an Ottoist bowling along at high speed as tricyclists do. There are tricycles that will carry 14 stone over all roads, weighing no more than 60lb. to 65lb.; one of these would suit him better. Rough roads are the last place for an Otto, from all I have heard of them. For rough roads, the main thing is a very soft spring, with 2in. or 3in. vertical play—this one can have on a tricycle—and there are some new, low-built, safety bicycles, with steering wheel running *in front*, driven by chain gear like a tricycle, on which one can enjoy the advantage of a tricycle spring; but on an ordinary bicycle, unless one rides a wheel much under his size, there is not room for a proper, high-play spring.

On the subject of springs I have some strong ideas; but as they are founded on positive experience and experiment, I am not afraid to insist on them. I may summarise them by saying that the springs usually supplied to riders by the makers are simply preposterous. Most of them are not worthy of the name of spring at all. Either they take a set and give way in course of time, so that the saddle falls out of position and tilts out of the horizontal; or if they are capable of holding up, it is simply by virtue of having no elasticity at all worth speaking of. But even suppose one has an Arab spring (and I think this is too well known for me to be thought guilty of advertising by assuming it the best), what happens then? The springs are stamped, each one with the weight they are thought suitable to carry, and happy (comparatively) is the man who gets one with his own weight stamped on it. But numbers of makers and agents (they have told me themselves) are in the habit of recommending their customers a spring marked two or even three stone heavier, and I have been told by riders that they could not get on without such extra-strength Arab springs; otherwise they got "bumped" down on the spring-carrier over rough roads. Well, I will explain the cause in a moment, but let me first give my experience. My weight varies from 13 stone to 13½, and I always ride a 10-stone Arab. It is perfection, and mind there is no mistake in the mark, for I have had four or five different ones on different machines, all 10 stone, nor has one ever broken or taken a set. My brother, who is 12 or 12½ stone, by my advice changed a 12 or 13-stone spring for a 10 stone, and is so pleased with the result that he thinks of changing for a 9 stone. With such a spring, and the saddle properly placed, one can ride all day without the least soreness, and roads that were a misery to ride on become comfortable. When roads are very good the spring is of little importance to speed, but when they are rough it is everything. No one without trying, as I have often done, can imagine the difference in speed that such a spring makes over rough or even ordinary roads. It is marvellous simply, and more important than any other single point about the machine.

Now, why is it some cannot ride even their proper weight Arabs without bumping? The difference is in the placing of the saddle. An Arab spring, firstly, should be placed so that the looped end of the spring points backwards. Some place it reversed, but the inventor recommends this position, and I have found it best. Then the saddle must be placed so that it rises and falls with the rider horizontally, or always parallel to itself, not more in front or at back, but always keeping horizontal from its lowest to its highest position. The position varies somewhat for different riders, and can only be found by shifting it till you feel it rises and falls parallel as you jump up and down sitting on it. Half an inch backwards or forwards from this position will cause it go all down, either back or front and bump as complained of, but when so placed you may safely ride a spring 25 per cent. below your weight, as I do, and thoroughly enjoy it. You will find, moreover, that the saddle seems to fit no matter how you sit on it; that a saddle which formerly cut you will now be perfect comfort in many cases, and that you may go for miles without bearing on your handles without finding any tendency to slip off the saddle, either backwards or forwards.

A great deal of this is not new; but I wish to insist on the huge importance of riding the softest spring, and with the highest play you possibly can. You should be able to make your saddle dance again with a blow of your fist, you should be able to bend it about in all directions with one hand on it, and it ought to settle down most perceptibly when you get on to it, and over rough ground it should dance like a "baby-jumper." To do this it must have a good high play; some springs have not an inch of play in them, they should have, I should think, about three. Bicycle riders do not know what a real spring is—they have no room for it.

I wish "D. H. G." would continue his advocacy of the free pedal; what a rest and comfort it is in a 50-mile run over undulating country, and what a pity people are oppressed with the idea that one ever practically needs to back-pedal when he has a decent brake. The use of it can be learnt in an afternoon.

I have ridden my machine (not intentionally) with the ball bearings full of sand. No harm was done, and very little heaviness was noticed. How about plain ditto with sand in them. How often do the plain-bearing people clean up?

I should very much like some opinions of the B. S. A. Safety Bicycle (Birmingham Small Arms Company) from any who have tried it.

**Norman.**

## MICROSCOPICAL—TWO EYES ARE BETTER THAN ONE—MONAD.

[24626.]—I CAN see no possible advantage in going to the expense of a right-angled prism, as in the commonest microscopes I find the mirrors quite good enough. One mirror I have gave me four or five images of the flame, which would, of course, be fatal to good definition. This, however, was corrected by turning the mirror round in its cell until a point was found where all the images overlapped. Another mirror I have is a concave, of about 10ft. focus. I find no difference for ordinary work. Any concavity in a plane mirror is bad, and ought to be avoided, because it shortens the focus of the condenser, which will be quite short enough, if it has any angle in it, without any further shortening.

I cannot say I can mention any definite object or object-glass in which I could perceive any difference with mirror or lamp direct. If anyone is doing very special work, and fancies some error due to mirror, then turn it aside, and use the lamp flame direct. I cannot see any advantage of a prism, which cannot possibly be so good as nothing at all. One special advantage in using the lamp flame direct is that one is not so liable to get the light out of centre. When a mirror or prism is used, a slight touch, or shake of the table even, is apt to throw it out of centre.

I regret that I know of no advantage in keeping both eyes open when using a terrestrial telescope. It would be a great saving to the eyes if you could do so. The following is the rule both for the microscope and telescope. You can use both eyes only when the stronger light is in the instrument; when the weaker light is in the instrument, then you must shut the unused eye. Microscope by diffused daylight.—The light in the instrument is the weaker: you must shut the other eye. By artificial light in a dark room, you can keep both eyes open. One hour of steady hard work with the microscope by diffused daylight will tire you more than a whole day's work in a dark room by lamp light.

With the terrestrial telescope, as 999 in 1,000 have smaller emergent pencils than ·11in., the light in them is less than the light in the unused eye, therefore the unused eye must be closed.

Sailors, as a class, know nothing about telescopes. In the merchant service they are never used, and seldom by the men in the Navy; it is only when the latter become shore loafers—i.e., coastguardsmen, that they have much telescope work to do. The instruments they are then supplied with are hardly worthy of the name of telescope.

Monad is rather an indefinite term; some monads' flagella should be easily seen with ½in., others, again, would be difficult objects with much higher powers. Perhaps the following may help E. B. Fennessy. The flagella of Volvox globator should be easily seen by a ⅓in. on dark ground by artificial light when they are in water.

**Edward M. Nelson.**

Shetland, August 3rd.

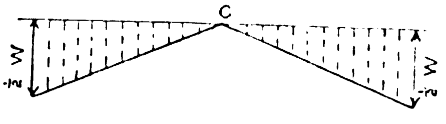
**Astronomical Instruments.**—An illustrated catalogue of Astronomical Instruments, Observatories, &c., manufactured by Howard Grubb, Dublin, has been issued, and will be found useful by astronomers and others, as it contains, besides a number of engravings of instruments and buildings, an explanatory diagram of Grubb's new ghost micrometer. W. Watson and Sons, High Holborn, are the London agents for Mr. Grubb.

# REPLIES TO QUERIES.

*⁂ In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[56676.]—**Free Reeds.**—I feel it my duty to reply to the remarks made by "G. L. B.," p. 503, in case anyone may be misled by his false ideas. 1st. The two queries (from which this discussion has emanated) were written by the same identical author, a gentleman who is anxious to know how to tune reeds simply for his own personal benefit. I do not hesitate to tell the truth, and inform interested readers that "G. L. B.'s" reply on p. 457 is "wide of the mark," and not my reply. I am justified in keeping to my previous statements, and to expose false ideas, even if they emanate from "an old member of the trade." 2nd. "G. L. B.," p. 503, quotes the prices charged for reeds as those of one London agent. To prove that reeds vary in price, irrespective of quality, I quote those charged by a well-known London firm. Esteve's, 4ft., 8ft., or 16ft. set, 18s.; best extra broad, 22s.; Turban's reeds, 17s. per set; extra broad, 21s. I could quote prices from numerous other lists; but what I have now quoted will enable "G. L. B." and those interested to draw some conclusion as to why I retain the "unalterable opinion" referred to by "G. L. B." on p. 503. 3rd. As "G. L. B." forms a false idea as to what I mean by "theoretical humbug," I will explain my true meaning on that point. In speaking of "theoretical humbug," I refer to replies which consist chiefly of suggestions regarding the subject of reed-voicing and tuning. Both reed-voicing and tuning can only be acquired by constant practice and experience in the art. To simply tell a querist, or explain to him the mere operation, is not sufficient in such a case, for that is really theory without practice, and as such is of little or no value. Hence the consistency of my previous remark, that we want more "practical information" and less "theoretical humbug." Theory is all very well in its place, but in many instances, theory alone is better omitted, because it does not always benefit the querist practically. 4th. By "misconception," I simply refer to false and mistaken ideas combined with rash conclusions, which are, from time to time, drawn from certain statements. I did not use either of the above terms in reference to any of the recent remarks made by "G. L. B." 5th. Personally, I do not object to be styled an "amateur," particularly when we come to consider that a real "professional" does not, in a general way, give advice or instruction gratis, either through private correspondence, or through the agency of a mechanical paper.—G. Fryer.

[56679.]—**Supported Beam.**—For the sake of the original querist, in a uniformly-loaded beam the shearing at the centre C is nothing, and increases to half the value of the load at the points of support. The intercept at any point between the horizontal and the sloping lines is proportional to the shearing at that point. When the load is at the centre the shearing at every point in the beam is half the value of the load. Will Prof. Goodeve give the meaning or intention of the original question in the number of May 22nd?—J. S. C.



[56937.]—**Tons Measurement.**—This is simply builders' or dock measurement. Builder's is taken from the dimensions.—J. M. T.

[56945.]—**Clarionetta, Oboetta, or Bassoonetta.**—Will this querist kindly say where he finds any mention of these instruments? Being personally ignorant of them, I hesitate to express an opinion; but if they are of the free reed type he may safely assume that they have not exactly the same tone as the instruments they are intended to represent. As I am professionally interested in learning all I can of the modern automatic instruments (so-called), I shall be glad of the information where these examples can be seen.—Gray's Inn.

[56948.]—**Gas-Producing Apparatus.**—To "Invicta."—My engine draws in the charge at every revolution, which is fired at about one-third of out-stroke without compression. "Z. Y. X.," in replying to this query, warns me that gasoline gas is more dangerous than common gas unless the generator has a good safety chamber attached; but I presume the generator you have described is perfectly safe, for I do not want to run the risk of an explosion. You will find my address in the proper column, and I shall be obliged if you call the manufacturer's attention to it. Many thanks for the information you have given me.—Gaseous.

[56950.]—**Hat Lining.**—The best thing "Saffron" can do is to have a new lining of unstained leather. I should take the hat to the dealer, and have something to say to him.—Essar.

[56950.]—**Lead Burning.**—In reply to "Finem Respice," we cannot see how, in your column of Replies to Queries, we are getting a gratuitous advertisement. We do not think it advisable to publish a copy of the specification of our "patent apparatus." What does it matter whether it is patented or not, so long as it does the work represented? If "T. R." will apply to the Patent Office he will be able to read, and also to obtain, a copy of our specification and number of patent, &c. We do not consider it necessary to have an attendant at our exhibit at the Inventions. Mr. Briggs is always there from 4 p.m. on Saturdays to answer all inquiries.—Briggs and Co.

[56950.]—**Lead Burning.**—For the information of "Finem Respice," and others interested, I may mention that application for a patent for "Apparatus for use in Soldering" was made by Thomas Briggs, on 1st October, 1884. The complete specification, bearing No. 13,026, of the said year, was accepted on 31st July, 1885. The complete specification will be published in a few days, most likely, and any notice of opposition to it may be given, on the prescribed form, within two months of the latter date. I agree with "Finem Respice" in thinking that Messrs. Briggs and Co., in exhibiting their apparatus at the Inventions Exhibition, might have indulged the public with some details as to its construction or mode of working—the more so, since, by application to the Comptroller on "Form O," this may be done without prejudice to the inventor.—H. B. F.

[56950.]—**Lead Burning.**—I am sorry to find that Messrs. Briggs and Co. are annoyed at my last letter, wherein I spoke of their lead burning on the merits of the actual work itself, which was true in substance and in fact. When people put specimens of lead burning into exhibitions, it is taken for granted that they do not exhibit the worst which they can do, and if these specimens are the best, they are certainly very inferior to ordinary lead burning. So far as their patent goes, I am a disinterested person, for I certainly would not use it in the present age, nor do I think that any one would, after they had tested the merits of gas-generating machines. If Briggs and Co. will take the trouble to make an appointment to meet me at my workshop, I will show them a machine constructed upon the same principle as theirs, and which was made and used at some buildings at South Kensington in the year 1880, but which was discarded by reason of its irregular action and unsuitability for lead-burning purposes; but as "Finem Respice" requires to know something more about this wonderful machine, I will, for his information, give him a few practical particulars. In the first place, the machine is cylindrical, ranging from 6 to 12in. diameter, about from 9in. to 18in. high. Inside the machine, or at any other convenient situation, is fixed an air-pump. In the bottom of the machine is fixed from 3 to 6in. of ordinary cotton waste, or other absorbing material, such as tow or the like, this material being saturated with methylated spirits, benzoline, petroleum, turpentine, or such like inflammable matter. From the before-mentioned air-pump we take a pipe to force air to the under side and through the before-mentioned saturated inflammable material, which air becomes charged with hydrocarbon gas, which is collected in the top part of the before-mentioned cylinder, which hydrocarbon gas is conveyed to one of Cotton and Johnson's or other blowpipe in the usual manner. I may add that, instead of using a pump direct, the air is much best if pumped from a water column bellows, such as is shown at Fig. 66, "Standard Practical Plumbing," which will allow the blast to work more steadily than is possible without such regulating apparatus. I have tried to overcome this irregularity by using Sugg's and other gas regulators, but prefer the water column.—P. J. Davies.

[56953.]—**Boracic Acid.**—Better leave boracic acid out of your jam. Boil your jam properly, and it won't ferment.—Housewife.

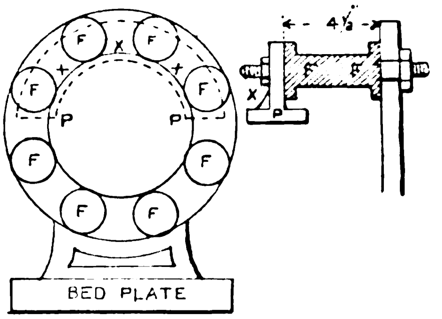
[56956.]—**Steam.**—This is simply copied from an examination paper, and can be readily answered by reference to the tables in the pocket books, or by looking up back numbers.—Essar.

[56957.]—**Ball Bearings.**—I can quite understand "R. R. N.," p. 481, preferring ball bearings because I fear sure he has never ridden a bicycle with plain bearings made broad enough and fitted properly. I have seen a great number of bicycles with plain bearings, and not one of the bearings was as broad as they should be—viz., about two and a half times the diameter of the shaft. If ball bearings are so exceedingly good and easy to work as some of your correspondents wish to show, how is it our railway engineers don't apply the ball bearings to railway carriages and so save a consumption of fuel; and, further, why is it our road carriage builders are not using the ball bearings and so save horseflesh? As an engineer, my advice to all bicycle riders is to abandon the ball bearings, and to have bicycles with plain bearings, made broad enough, with the patent needle lubricator.—Chas. Hosken.

[56962.]—**Legal Telephone Query.**—If the royalty has been paid, and the payer has to keep his telephones in order himself, I don't see how any action would lie against those who did the repairs.—Limb o' th' Law.

[56964.]—**Steam Blowing-Engine.**—A steam blowing-engine is simply an engine working a pump that pumps air. The pump cylinder has valves which open inwards and admit air which is driven out by the motion of the piston. An engine that condenses the steam has only about 3lb. back pressure (or less), instead of 15lb. See any textbook.—Essar.

[57049.]—**Gramme Dynamo.**—To Mr. Bottone.—In compliance with your request, I submit sketch of my dynamo. The circular supporting frame is of malleable iron, to which the field magnets F are bolted at one of their ends; they also are of malleable iron, and were described on page 442, and a preceding number (1057). I have only shown the upper pole piece, and that in dotted line, to be better understood, and to further explain my meaning, I have separately sketched a field-magnet, F F, bolted to one of the semicircular pole pieces. Having spent much time and expense in fitting up so far, I am anxious to have the correct size of armature and consequent width of embracing pole pieces; also to know the number of cogs on the ring, and the width of the sections between them. References to sketch: F, flanges of field magnets; F F, body of field-magnets where wire goes on, and $1\frac{3}{8}$in. diameter; X are feathers for strengthening pole pieces.—Subscriber from No. 1.



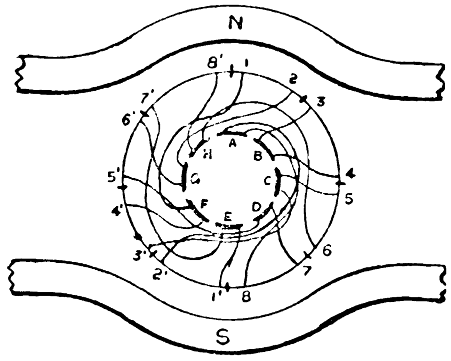
[57055.]—**Electric Bells in Series.**—To "M. S. E."—I understand that you require the bells to be in series, and that they are to ring independent of each other. I think we are as far off the problem as ever we were. The description of Jolin's double-wound bell, given by Mr. F. B., p. 483, July 31, does not give the required object—independent working (he does not state that it does. I merely wish to call your attention to the fact.) The double winding in that particular case simply obviates the contact pillar, common to the generality of bells. While, against it, I have the following ideas:—That if the iron cores are not exceptionally pure (ditto armature) the preponderating current will cause it to "stick" in a certain degree. If the wires are not the same resistance, ditto, ditto. If they are not practically differential, ditto, ditto. The lessening of the resistance is immaterial in a house bell, but two stations, A, B, five miles or more apart, would find it is not so convenient or reliable as a single-wound bell of double the resistance. Perhaps it is not generally known that no machinery is required for double winding beyond the usual "throw" and one's hands. The main object is that the two wires are not allowed to separate in running on the bobbin. I have wound dozens of differential galvanometers, so speak from practical experience.—Experimenter.

[57057.]—**Transmission of Power by Belts.**—To "S. S. N."—Thanks for your offer to correspond. I here find another difficulty—namely, in finding the tension of the belts.—N. E. Crosthwaig, The Lodge, Baggnalston, Ireland.

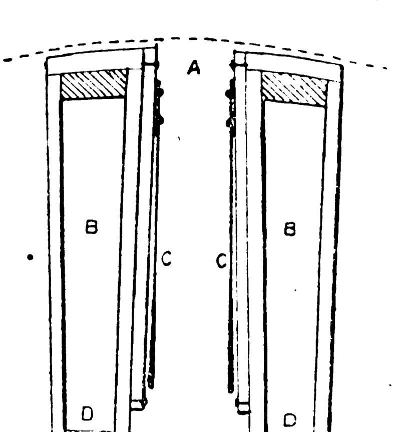
[57059.]—**Power.**—I beg to call "Nester's" attention to what is evidently a mistake, or misprint, in his answer to this query. Leaving out of the question the work done by the man in carrying his own body upstairs, as well as the work done in moving it, and the weight the horizontal distance measured on the plan of stair—viz., 22 cos. 60° feet, we have the useful work as $\sqrt{\frac{3}{4}} \times 110 \times 22$ ft.-lb. This also should be the work done when the weight is lifted by means of the pulleys, leaving out, of course, the weight and friction of pulleys. The answers given, however, differ to the extent of about 550ft.-lb.—David Stephen.

[57064.]—**Bisulphite of Soda.**—In his directions for preparing this substance Percy W. Stanley makes a strange blunder. Sulphurous-acid gas should, of course, be passed through the solution of sodium carbonate, not sulphuretted hydrogen.—J. T. M.

[57072.]—**Siemens - Alteneck Armature.**—To Mr. Bottone.—A laminated armature would not do for this. The principal distinctive feature in this armature consists in the length of the core, as compared to its diameter, and in the mode of winding. Longitudinal coils of wire completely envelop an iron cylindrical core, all the sections being wound at equal angular distances from each other around the surface of the core, and parallel to planes passing through its axis, longitudinally there being as many planes as there are sections to be wound. The sections of wire wound upon the core consist each one of two separate coils, having naturally two extremities; so that there are twice as many ends as there are coils. These ends are brought out two by two to a number of copper sectors, insulated from one another, which together build up a cylindrical commutator, much resembling that of the Gramme machine, and rigidly attached to the armature spindle; the currents are collected in a similar manner by conducting brushes pressing against the commutator as it revolves. The annexed diagram shows, as far as it is possible in a sketch, how the ends of the coils are connected to the sectors of the commutator. In this diagram the two ends of the same coil are figured respectively 1 and 1′, 2 and 2′, &c. To avoid confusion the armature is supposed to be built of eight coils only, though the more are used the steadier the dynamo is in action. If these connections be traced, it will be seen that all the coils are united into one continuous circuit, the commutator sections being traversed in succession.—S. Bottone.



[57079.]—**Windway.**—As a supplement to the replies on p. 484, I send a sketch which will explain one plan how to arrange two sets of reeds to be actuated on the suction principle, with paper bands or strips. In this case I have chosen the system without levers as the most simple for explanation. In sketch, A shows the opening or pallet aperture through which the wind enters, and over which the perforated paper (shown by the dotted line) passes. B B are the reed channels or tubes similar to those of the harmonium pan. The reeds C C are allowed to slide in or out, but differ from those of the American organ as regards position, as the reeds in this case must be situated outside instead of inside the tubes. The air is drawn downwards through the apertures D D in lower end of tubes, as shown by the arrows. The American organ cavity boards are not in any way suitable for automatic reed organs except they are constructed on the barrel system, as suggested by a correspondent on p. 484. I am afraid that "A. B. C." requires too much in a small compass. I may suggest that he can have three, or even four, rows of reeds in a very trifle more space than that occupied by two sets of reeds, if he intends to use the A. O. cavity boards on the barrel organ system. This would not be a very portable affair, it is true. I have now in preparation my promised instructions how to make an automatic reed organ to contain thirty-seven reeds or three chromatic octaves, which I hope will prove interesting to many of "ours."—G. Fryer.



[57080.]—**Siphon.** — In reading the valuable replies to my query I am very much struck with the uniformity of opinion. Having held the same idea, I took steps to provide for this air escape by fixing on a small valve at the summit. The valve was placed inside a large-sized air-vessel (same as used on force pumps), having a small stop-cock on top. By this arrangement I anticipated that the air which escaped out of the siphon would have room to expand in the vessel, and would not hinder the working of the valve for some considerable time, meanwhile acting as a sort of spring weight thereon, and when there were signs of sluggish flow the stop-cock could be opened for a little so as to reduce the pressure again. I also tried the effect of leaving the stop-cock open and covering, or trapping the valve with water poured through the tap. Unfortunately, I had good reason to doubt the tightness of the main pipe, and the valve failing to mend matters confirmed my suspicions. A small nozzle $\frac{3}{16}$in. was let into the main at the neck of the ball-cock, to try, by continuous flow, to make the siphon clear itself. Possibly, if this aperture was made larger, it would do so, but the water cannot be spared. As I wish again to try a valve on the pipe before condemning for leakage, I would be glad of drawing and description of a suitable valve. "Invicta" appears to have mastered the difficulty before; will he kindly come to the rescue? There is already a suction pump fixed up at a point below level of tank bottom, and within 150 yards of the ball-cock, which draws the water in five minutes. Would "R. R. N." and others kindly note that the slip was mine—not the printer's?—Surveyor.

[57083.]—**Freemasonry.**—I do not think "Z." was far from the mark when he spoke of "Freemasonry as a mere benefit society." As such it is entitled to all respect, and if it is now looked upon only as the fossil remains of what it once was—viz., an institution to which we are indebted for the most wonderful works of art the world ever produced, it ought still to command a certain amount of interest and respect. Sinnett, in his "Occult World" traces it up to a very early age; but he says that though it has copied the old formula, its *raison d'être* has expired here with the expiration from Freemasons of the occult philosophy on which their forms and ceremonies are shaped to a larger extent than they generally conceive.—Z. A.

[57083.]—**Freemasonry.**—In reply to "Z," there is no advantage in becoming a Freemason in the sense of a friendly society. There are two schools, one for boys and one for girls, splendidly maintained, and which are probably not equalled by any similar institutions. There are, however, usually more candidates than vacancies, so that a considerable amount of influence is generally required to be successful. There is also a charity for the aged, conducted in a similar manner. Any person having from £10 to £15 to spare, and without feeling its loss, and who would not object to pay from £2 to £3, or more, annual subscription, would, if he joined a good lodge, have the advantage of being introduced to a society of considerable respectability and often of influence, which would be of considerable service to him in the event of being compelled to reside in another town to which he is a stranger. Any Freemason meeting with misfortune would, in all probability, be assisted if he applied for assistance; but he would be entitled to nothing by right. But any person becoming a Freemason, and advertising himself as such for the purposes of trade, either by wearing scarf-pins, or using the sign in circulars or invoices, &c., would most certainly be ignored by all those Freemasons whose good opinion is worth having. Such a practice, although it is frequently resorted to by publicans and others, is thoroughly contrary to the principles of Freemasonry.—Hiram.

[57086.]—**Colliery Warnings.**—After reading Mr. Murray's reply to this question, I suppose "Ralph" will, for obvious reasons, respectfully decline to believe in the accuracy of the so-called colliery warnings.—Bacchus.

[57121.]—**Mountain Snow.**—"Nester," page 485, only gives a statement of facts, and not an explanation; but perhaps the following will help "Ignorant" over his difficulty:—The rays of the sun consist, in addition to the luminous rays, of invisible heat rays, which last, in passing through the atmosphere, are absorbed by the aqueous vapour present in it, so that only the small heating power of the luminous rays is able to be used to melt snow. Now, on striking the snow, these luminous rays are reflected back unaltered, and, therefore, their heat is not used to melt the snow; but on striking the earth these luminous rays are reflected upwards, principally as invisible heat rays, and since the aqueous vapour in the atmosphere absorbs these considerably, the farther a place is from the general level of the ground the less warmth is it able to get, and therefore on the tops of high mountains the summer sun is insufficient to melt the winter snow, so that it accumulates.—W. Scudamore.

[57122.]—**Problem.**—Let $\angle CAB = \angle CEF = x$. Then—

$$\frac{1}{\cos. x} + \frac{2}{\sin. x} = 5$$

$$\frac{\sin. x}{5 \sin. x - 2} = \sqrt{1 - \sin.^2 x}$$

$$25 \sin.^4 x - 20 \sin.^3 x - 20 \sin.^2 x + 20 \sin. x - 4 = 0.$$

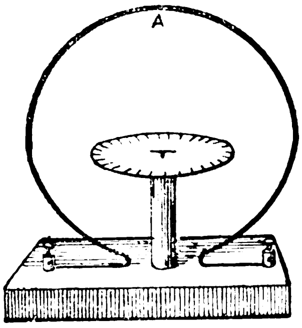
$$\text{or, } \sin.^4 x - \cdot 8 \sin.^3 x - \cdot 8 \sin.^2 x + \cdot 8 \sin. x - 4 = 0.$$

Which gives sin. $x = \cdot 52$, and $\cdot 94$ nearly; and B C = 50 . sin. $x$ = 26ft., and 47ft. nearly. The ladder may evidently assume two positions, both fulfilling the terms of the problem. I do not see how the biquadratic equation is to be avoided.—W. A. S.

[57124.]—**Lifting Bar.**—To "J. S. C."—If your view of this matter is correct, it would appear that the querist could exert himself greatly without doing any work; and by sequence it is reasonable to assume, by the same line of argument, that a man's muscular energies might be altogether exhausted in this manner, without ever being brought into motion. Would "J. S. C." be prepared to support his theory to this extent.—Bacchus.

[57124.]—**Lifting Bar.**—If you seize the bar near the end to lift it, you certainly do no more work than you do when you lift it by the centre, for the simple reason the bar will take up a vertical position, the centre of gravity falling to the lowest point; but if you wish to hold it in an inclined or horizontal position during the process of lifting, then you are quite wrong in supposing no more work is done. A pillar supporting a heavy weight does no work; but if I were to assert, as some do, that a man standing with a weight on his back does no work, I should be contradicting my own experience. In this case, the hand is the fulcrum of the lever, the reaction of the elbow is the power that balances the weight of the bar and keeps it in the inclined position. It is this reaction that causes the extra work over and above that done in lifting the bar, though it no more moves than does the man who stands with a weight on his back: it does work in the true mechanical sense of the term.—David Stephen.

[57126.]—**Obach's Galvanometer.**—In the ordinary tangent galvanometer, of which the annexed is a rude sketch, the ring A, which conducts the current is a fixture. In Obach's modification the ring can be inclined from the vertical; when, if the ring be inclined at an angle $\theta$, and $\delta$ be the deflection, then the current is equal to tangent $\delta$ secant $\theta$.—S. Bottone.



[57127.]—**Lactic Acid in Milk.**—Milk containing this acid in any quantity strongly reddens blue litmus paper. The amount can be determined only by chemical means.—J. T. M.

[57127.]—**Lactic Acid in Whey or Milk.**—In order to determine the amount of lactic acid in milk you must titrate the sample with a solution of soda or potash of known strength, and from the amount of alkali required for neutralisation the quantity of acid can easily be calculated.—A. Price.

[57128.]—**Storage Battery.**—I beg to thank "Bunsen" for his offer with respect to the above; but not being an adept at algebraical equations, I cannot give him the E.M.F. of lamp and battery, but will give him full particulars, which I think will answer the same purpose. The lamp is one of Swan's 5 c.p. incandescent globes, fitted on small lamp stand, and kept in position with spiral spring, and is connected directly on to the battery by about a yard of wire from each terminal. The battery consists of 8 carbons and 5 zinc plates, the carbons being 8in. by 3in., and the zincs 4in. by 3in., and the charge a single fluid, bichromate of potash solution. For convenience it is wished for the storage battery to be circular, 3in. in diameter. How many plates will it require this size, or how would it answer for one plate 4in. deep, coiled into a spiral 3in. in diameter? Thanking any of our readers in anticipation for their opinion on this subject.—WERDNA.

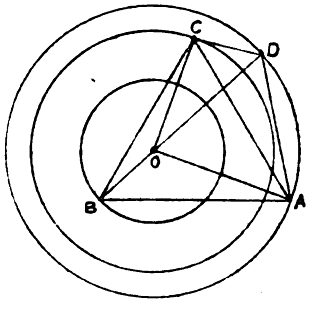
[57130.]—**Pump.**—I could tell you of a plan which would not necessitate pumping at all, and would deliver the water in a continuous stream without any labour. If you will advertise your address, so that I may have full particulars as to what quantity of delivery, &c., you wish for, I could then communicate with you, or anyone else, on the subject.—P. W. R.

[57130.]—**Pump.**—Since the height which the water has to be raised (about 30ft.) is nearly the length of a column of water equal to the pressure of the atmosphere (averaging about 34ft.), and the water has to run through 450 yards of piping, most probably a force pump at the bottom of the field would be required, although possibly a common suction pump at the top of the field would do the work.—W. SCUDAMORE.

[57134.]—**Easton's Syrup.**—This a solution of quinine, strychnine, ferrous phosphate, and sugar in diluted phosphoric acid. It is a powerful tonic, but should not be taken without medical advice. —J. T. M.

[57135.]—**Varnishing Fancy Woods.**—My brother recommends "T. J. A." to brush his box over with a thin coating of glue; this will act as size always does, by filling the pores and preventing the varnish sinking in.—H. O'B.

[57147.]—**Geometrical Science Examination.**—From a point O as centre, and the three given distances as radii, describe three circles as in diagram. Draw any radius O A to the outer circle.



From A as centre and radius A O, describe an arc cutting the outer circle in D. From D as centre and radius O B describe a circle cutting the middle circle in C. Join A C, and make the angle O A B equal to C A D, and let A B cut the inner circle in B. Join B C, then A B C is the required equilateral triangle. Because A D = A O, and A O = O D, therefore the triangle A O D is equilateral; and in the triangles A O B, C A D, we have A D = A O, and D C = O B, and the angle O A B equal to the angle C A D; therefore the triangles are equal, and A C = A B, and therefore the angle A B C = A C B. But from the construction the angle B A C = the angle O A D; and therefore = 60°, therefore each of the angles A B C, A C B = 60°; and hence the triangle A B C is equilateral, and the distances from the angles to the point O are equal to the given distances respectively.—J. E. GORE.

[57154.]—**Horse Taming or Breaking.**—"The man of kindness to the beast is kind," and the beast fully appreciates his master's kindness. Try it! Be your own pony tamer; you will feel proud all your life long in being so, and may save your five guineas. Put away the whip, never let the pony see or hear the crack of one! Make a pet of him, as you would a little child; stroke his nose, scratch his ears, rub his skin with your hand; feed him with a "tit-bit" every time you go near him—a lump of sugar, a crust of bread, a carrot, an apple—all the while speaking to him in a soft voice and with coaxing words, all of which he will understand fully as well as yourself; never lose your temper with him, and then you will never excite his. Men (and women) have done this; so may you. But be very patient. The years of hard usage have to be obliterated from the animal's memory, and this will require months to effect—possibly the year round; but I again say, Be very patient and invariably kind and good tempered, and you will be amply repaid in the future obedience and friendship of the pony, and please to let "Ours" have the result of your efforts. I think our indulgent and judicious Editor will insert your letter. The horse tamers do wonderful things, I well know, one of which is to *tame* the ostlers, &c., who are engaged in the stable, and if *you*, "M. H. J.," use the whip as you describe, you require *a taming* also!—H. O'B.

[57156.]—**Gauging Railway Waggon Axles.**—I think if a pair of waggon wheels are found 1¼in. out of gauge, it is something "to speak of," and would say the cause of the waggons leaving the rails was not far to seek if the wheels were this far out of gauge. There should be no sign of strain in a waggon axle when under load. If vehicles were running with wheels anything like 1¼in. out of gauge, there would be no end to accidents such as the one which led to the inquiry "T. J. S." writes about. There would be more broken axles, and everyone knows that many of the most serious of railway accidents have occurred from the breaking of an axle. If deflection does take place, it must continue while the wheels are rotating, because the load which causes it at rest is still upon the axle while it is revolving. It would depend entirely upon the diameter of the wheels to determine how much the axle is bent when the wheels are a certain amount out of gauge. That is if the wheels were (as I expect they have been) gauged between the tires.—TOPIC.

[57158.]—**Bird Taming.**—The best way to tame your birds is by kindness and familiarity with your company, tempting them to come to you by litttle treats in food, &c., petting and coaxing them in all ways, and getting them to have no fear of your voice and figure. This is easily done. It of course requires a little time; but by patience and perseverance you can get a bird to do almost any little trick, and when he gets into it he will enjoy the fun as much as you. Of course the birds most easily tamed are those of your own breeding. There is no wonder the Italians would not tell you their method, for you and all right-minded persons would quickly withhold any sympathy with them. Their process is cruelty; the bird is kept in darkness, in a cage barely large enough for him to stand in, without food or water, except such as his owner gives him on his going through some little performance. Hundreds of birds are sacrificed in their training process by these vile rascals, and few comparatively attain to such proficiency as to be exhibited before a crowd of gaping fools, who are satisfied to see the antics of the poor little creatures, and do not think nor care about the cruelties they have survived in learning them. If you want your birds to be tame with you, give them light, air, freedom to exercise, good food and water, and plenty of your company, and you'll succeed, or the fault will be yours; but don't attempt the means used by those Italian scoundrels as you value your self-respect and the affection of your little captives. —MARCUS.

[57159.]—**Watch Query.**—Although "Caribbean" says that his watch is in good order, I very much doubt it, as if he cannot put on a hair spring he is less likely to know whether the rest is in good order. The principal part of the verge is the escapement; if this is not in order, it is useless to put on a hair spring until made perfect. I advise him to study the papers that appeared some time back for reference to above, and if he likes I will tell him what I may know to help him.—P. W. R.

[57162.]—**The Micro. O.G.**—To "ROB. CRUS." —I feel sure that "J. T." will find brass, iron, glass, or zinc, almost anything in fact, better than lead for grinding lens surfaces. It would be better also to get the mastery of emery alone, and eschew rottenstone, &c., in the grinding, for it really is not hard enough to grind glass, being only silica itself. The polishing of all lenses down to ¼in. focus may be done best on pitch with rouge, and will never succeed on lead. For shorter-focus lenses the materials used are of a harder nature, because the tiny lens penetrates the rotating polisher. Up to ⅛in. focus, polish on pitch hardened with resin "to taste"; up to $\frac{1}{16}$in. or $\frac{1}{20}$in. focus, polish in good sealing-wax. A bit of *pure tin* may be used for lenses up to $\frac{1}{30}$in. focus. After that you must find out for yourself what to use. The words "when cemented" mean when united by means of Canada balsam. I never permanently fix my lenses in their cells for many reasons, but principally because amateur work is always more or less experimental, and I find it very convenient at times to be able to make experimental changes in an o.g., such as could not be done if the lenses were fixed. The other lenses required to complete the microscope are two plano-convexes for an eyepiece. The field lens should fill up the body tube as much as the necessary fittings will allow, and as the tube is 1¼in. diam. the field lens may be 1⅛in. diam.; and if made of 4in. solar focus, it might have a ⅝in. eyeglass mounted at a distance of ⅝in. from it, which would make an ocular equal to a 2in. lens—that is, having a power of five diameters or times. I believe that an ocular of twice the above power might be made with a field glass as large as the above. I will endeavour to send another letter for our next issue on the mounting of the various kinds of lenses used in the microscope; but if any more queries are addressed to me, I am afraid they will have to stand over for about three weeks, as I am away from home for about that time, and "our" paper does not follow me. The assertion above that the field lens should fill up the body tube only applies to low-power oculars, for the higher powers it means, make the lenses as large as possible for the sake of the field; but do not misunderstand the word "possible."—ROB-CRUS.

[57163.]—**Employment in the Arsenal.**—It may interest the querist to know that employment at this place is so much sought after, that for every opening there are a hundred applicants.—BACCHUS.

[57163.]—**Employment at Woolwich Arsenal.**—Apply at the office any morning at nine o'clock. A letter of recommendation would be of service. I only write of the Royal Laboratory, as I know nothing of the mode of entry to the other departments.—SENSITIVE FUSE.

[57164.]—**Trigonometrical.**—The complement of the greater angle of depression is equal in this case to the lesser angle of depression. Calling this angle $a$, the height of the vertical column is

$$\frac{108 - \sqrt{\frac{4\,(108 \tan. a)^2}{3}}}{2} = 72\text{ft.}$$

—BACCHUS.

[57164.]—**Trigonometrical.**—Let A B be the top and bottom of tower respectively. From A make the angle B A C = 30°, C being on the ground, through C draw the vertical C E, meeting the horizontal through A in E, then make E A D 30° cutting C E.

$$AE = \frac{1}{\sqrt{3}} \times 108 = \frac{\sqrt{3}}{3} \times 108 = \sqrt{3} \times 36$$

$$ED = \frac{1}{\sqrt{3}} \times AE, \text{ i.e., } \frac{1}{\sqrt{3}} \times \frac{\sqrt{3}}{1} \times \frac{36}{1} = 36$$

$$CD = CE - ED = 108 - 36 = 72\text{ft.}$$

—E. E. P.

[57164.]—**Trigonometrical.**—Let A B = height of tower, C D that of column; join A C, A D; then from the given angles of depression we have L A C D = 120°, L A D C = L D A C = 30°. Now from the fact that the sides of a △ are proportional to the series of the opposite angles, we have

$$\frac{108}{AD} = \frac{\sin. 60^\circ}{\sin. 90^\circ}$$

$$\therefore AD = \frac{108 \sin. 90^\circ}{\sin. 60^\circ}$$

Again, in the △ A D C,

$$\frac{AD}{DC} = \frac{\sin. 120^\circ}{\sin. 30^\circ}.$$ Substitute value for A D.

$$\frac{108}{DC \sin. 60^\circ} = \frac{\sin. 120^\circ}{\sin. 30^\circ}.$$

$$DC = \frac{108 \sin. 30^\circ}{\sin. 60^\circ \sin. 60^\circ}$$

$$= \frac{108 \times \frac{1}{2}}{\frac{\sqrt{3}}{2} \times \frac{\sqrt{3}}{2}} = \frac{54}{\frac{3}{4}} = 72\text{ft.}$$

It is interesting to note that (Bk. I. vi.) the distance of top of column from top of tower is also 72ft.—DAVID STEPHEN.

[57171.]—**Hardening Punches.**—I think, with you, that the difficulty is in the shape of the punch. A taper punch will, of course, jam. Is it not possible to punch the shoes hot? or to drill the holes first, and then punch out what is left to make them square; there would not be quite so much metal to take out, and you could use a straight punch, or even relieve it a little at the back. I suppose the holes are square. There is really only one way to harden and temper the punches, and I don't expect you want that information.—OS.

[57173.]—**Easing Force Pump.**—Perhaps the packing is too tight, or the pump handle too short. —OS.

[57173.]—**Easing Force Pump.**—"Rector" does not say what class of pump he has. If, as I presume, an ordinary brass 3in. pump, fixed on plank, and bolted to wall, with 30 vertical feet, 1½in. suction pipe, it is clear it is now doing more than it was ever intended for, and in cases of this sort I should recommend a deep well pump, with vertical suction—say, 20ft. However, his best plan to adopt will be to apply a fly-wheel to the pump motion, which will certainly have a beneficial result.—W. H. WILDIG, Grosvenor-road, Chester.

[57177.]—**Soldering.**—Dip the nose and tin it over. Take care not to overheat it afterwards.—BACCHUS.

[57177.]—**Soldering.**—Perhaps you have a bad piece of copper in the iron; if so, it is very troublesome. I would advise not using it any longer. Of course you file the copper clean, smooth it off with an old file, take off corners, tin on a piece of sal-ammoniac. You must not get your iron to so high a heat as black.—R. PARKS.

[57177.]—**Soldering.**—Heat the copper bit and file it clean; then tin it properly with solder and soldering fluid, and don't let it get too hot (that is the great secret), or the solder will get burnt on to the copper and leave hard spots. Use a clear coke fire. Make a little round stove out of a piece of sheet iron, and take care that the bit is placed in such a position that it cannot burn. Keep your eye on it, and judge the heat by holding it up to your face occasionally.—Os.

[57177.]—**Soldering.**—If "New Beginner" will only keep his soldering-iron properly "tinned," and use properly-made solder, he will have no difficulty in keeping the solder on the iron. To tin on iron, heat it to the usual heat, and file the soldering surface well. Have some powdered rosin ready, put it on a piece of tin or a flag of stone; melt a small piece of solder over it, and rub the filed portion of the iron backwards and forwards through the melted mass until the iron is tinned. Any further information will be gladly given.—Greta.

[57177.]—**Soldering.**—I am afraid "New Beginner" fails to place his copper bit in order before he commences to solder; he must face it, before attempting to solder, by filing end perfectly clean while slightly hot, and rubbing same, say, on a piece of tin, using at the same time either rosin or spirits of salts killed, with a little fine solder, taking care in future not to burn away the face by getting the iron too hot. By attending to this he will, with a little practice, get on all right with his soldering.—W. H. Wildig, Grosvenor-street, Chester.

[57177.]—**Soldering.**—In reply to querist, Is he soldering with rosin or spirits of salts? If the former he must clean his bolt end very carefully with the file while hot, but not too hot, as the copper oxidises too quickly, then rub the copper along with some rosin and solder on a firebrick. If he uses "spirits" the bolt tins more easily; when moderately clean the copper only requires its point to be dipped into the "spirits," tinning readily on the solder. We used to use sal-ammoniac in Germany to clean and tin our bolts with; but I don't think it was better than our usual way here.—A Tinker.

[57177.]—**Soldering.**—It is not clear to me, as you sign yourself "New Beginner," whether you are trying to do the work with a plumber's wrought iron, or with what you should have, which is a "copper bit." As I am well used to soldering the various metals used in experimenting by me, it may be of some use to others as well as yourself to know my modus operandi. First, then, procure, say, 2d. worth of hydrochloric acid or spirits of salts, as it is usually termed; put some of this into, say, an empty jam-jar, also some pieces of zinc, pure if you can get it, but the sheet will do at a pinch. Do this in the open air, or, at least, on the kitchen hob, as the fumes are deleterious. When it has ceased to effervesce add an equal quantity of water to what remains in the jar, and it is ready for use. I use an arrangement of Bunsen burner of my own design, which keeps the bit at a uniform temperature all day, so that it does not require to be re-faced once in a month. To face the bit heat sufficiently to feel pretty hot when held near the cheek, file up with a smooth file which has never come into fellowship with paraffin oil (which is the enemy of solder and lead, but the friend of him who wants to clean his hands after the day's work). Have a strip of tin in the bottle with the soldering fluid, and put a drop or two upon the solder, and then apply the copper bit with clean face and sides. If your tin sheet is new, and you don't want to use the fluid, have some sal-ammoniac and powdered rosin damped, in a little box, and tin the bit with this (by dipping its nose in it), and then use powdered rosin alone on the new sheet tin. Run your solder into long light strips by melting in a ladle, and pouring on to a slate set at an incline, and by practice you ought to be able to hold bit in one hand and solder in the other, and so go ahead quickly. Mem.—Rinse the work well after using the acid.—A., Liverpool.

[57181.]—**Heating Greenhouse.**—"Thermo" cannot do better for success in his horticultural efforts than the "hot-water pipe again," of which numerous cheap and ingenious apparatus are advertised in *Gardening*, and elsewhere. The chief merit of the hot-water apparatus is the moist heat it gives off, which is a great deal more beneficial than the peculiar dry heat of the stoves. The fire, the source of endless dust and rubbish, on the floor of the greenhouse and the leaves of the plants, is outside, which enables the house to be kept in a respectable state of neatness. The presence of a fire in a greenhouse, apart from the question of neatness, is in the highest degree injurious to the well-being of the plants, causing the leaves to wither, and the advent of a respectable flower, except on some accommodating plant, an event of somewhat rare occurrence. The hot-water pipes are under the staging; whereas the stove is usually in the middle of the greenhouse, is a source of continual annoyance, besides taking up valuable space. Another consideration in frosty weather is when the fire goes out, which will rarely happen after some experience in banking-up at night; in the one case the hot water takes some time to cool, and consequently the fall of the temperature is not so rapid as when a stove goes out. Again, should the stove smoke, there is an exceedingly disagreeable odour, and a thick layer of soot over every leaf, flower, shelf, and in fact anywhere it can possibly be found. This takes an incredibly long time to get rid of thoroughly, and would be enough in itself to cause an inexperienced amateur to give up in disgust. Beyond the initial expense, I do not think that there is any real difference in the cost for a small greenhouse between the two methods of heating.—Amateur.

[57182.] — **G.N. Locomotives.** — Cylinders, 18in. by 28in., diameter of driving wheels, 8ft.; diameter of trailing and bogie wheels, 3ft. 6in. Wheel base: From centre of bogie pin to driving wheel, 10ft. 9in.; from driving wheel to trailing wheel, 8ft. 8in.; extreme wheel base, 22ft. 11in. They are not the largest, for most of the G.W.R. b.g. singles are 8ft., and I believe a new b.g. engine is building with 9ft. wheels.—Angus MacMuir.

[57182.]—**G. N. Locomotives.**—The cylinders of these engines are 18in. by 28in., bogie wheels 3ft. 10in. diameter, trailing wheels 4ft., driving wheels 8ft., extreme wheel-base 22ft. 11in., length of connecting rods 6ft. 10in. Their weight in steam is 39 tons, 16 of which are on the drivers. The largest wheel in this country is that of old 173—"Cornwall"—on the L. and N. W. Railway, built in 1847, and the only one of her class, which is 8ft. 6in. in diameter.—W. B. P.

[57182.]—**G.N.R. Engines.**—The chief dimensions of the G.N.R. single drivers are these:—Cylinders, 18¼in. by 28in.; wheels, leading bogie, 3ft. 11in.; driving, 8ft. 1in. (with tire); trailing, 4ft. 1in.; tubes in boiler (brass), 217; diam., 1¼in.; total wheel base, 22ft. 6in.; rigid, 8ft. 9in.; centre of trailing axle to bogie pin, 19ft. 5in.; connecting rod length, centre to centre, 6ft. 10in.; heating surface (tubes), 1,043; firebox, 122—total, 1,165; grate area, 18in.; weight, leading bogie wheel, 7tons; trailing, 8tons; driving, 16tons; trailing, 9tons 10cwt.; total weight in working order, 49tons. These engines have not quite got the biggest wheels; the L.N.W.R. have an 8ft. 6in. loco. called the Cornwall, running on the Liverpool portion of their line. It is not a success, and was only made for an experiment. No more have been made. The G.W.R. broad gauge have the same size of wheel as the G.N.R. I do not know the length of the boiler, but will do my best to find out.—A. A. C., Chiselhurst, Kent.

[57182.]—**G.N. Locomotives.**—If by "single drivers" "V. J. B." means the bogie single engines, the following are some of the leading dimensions thereof:—Diameter of wheels: bogie, 3ft. 11in.; drivers, 8ft. 1in.; trailers, 4ft. 1in. Wheelbase: Bogie, 6ft. 6in. (the bogie-pin being 3ft. 6in. behind the leading axle, and 3ft. before the trailer); bogie-pin to driving axle, 10ft. 9in.; driving axle to trailing, 8ft. 8in.; total wheelbase, 22ft. 11in. Boiler: Length of barrel, 11ft. 5in.; height of centre line above rails, 7ft. 1in.; minimum internal diameter, 3ft. 9½in.; maximum internal diameter, 4ft. 0½in.; plates, ½in.; 217 tubes, 1⅝in. diameter, 11ft. 8in. long. Outside casing to firebox: Length, 6ft. 2in.; width at bottom, 3ft. 11½in.; width at centre line of boiler, 4ft. 1½in. Firebox: Length at top, 5ft. 4½in.; at bottom, 5ft. 5in.; width at bottom, 3ft. 3in.; height at front, 5ft. 10½in., at back, 5ft. 4½in. Grate area, 17·6 sq. ft. Heating surface: Tubes, 1,043, firebox, 122; total of 1,165 sq. ft. Boiler pressure, 140lb. Smokebox: Length inside, 2ft. 8¾in.; radius of top inside, 2ft. 4½in. Diameter of blast-pipe, 4⅝in. Length of connecting-rod, 6ft. 10in.; eccentric rods, 5ft. 10in.; throw of ditto, 3¼in.; expansion links (curved), 1ft. 4in. long. Length over buffer beams, 28ft. 1in.; distance apart of frames, 4ft. 0¼in.; thickness of ditto, 1⅛in.; width of footplate, 7ft. 5in.; height of ditto from rails, 4ft. 2in. Weight of engine No. 1 in working order, 38 tons 9 cwt.; tender, 26 tons 10 cwt., carrying 2,700 gallons of water and 3½ tons of coal. Average consumption of coal, 26lb. per mile. In conclusion, I might add that the cylinders, being 18in. by 28in., give a tractive force of 91½lb. per lb. of steam pressure.—St. Aubyn's.

[57183.]—**Planing Machine.**—The smallest planers all take from 8in. to 10in. in height. Consequently you should find no special difficulty in that respect. To talk of 4in. being the maximum in the case of your machine seems ridiculous. But firm fixing is always essential, and I should say your angle plates are undoubtedly too small to hold work 10in. in depth. You had better have another pair 6in. or 7in. deep. A deep angle plate firmly bolted to the table will hold work as deep as the planer will take. When the nature of the work will permit, it is often held firmly by screw bolts passing from flanges or through holes at or near the top down to the grooves; either with deep angle plates having broad feet, or with long screw bolts, deep work can be held securely.—J. H.

[57184.]—**Headstock.**—To "Cui Bono."—An unsteady arrangement, I should imagine. Before I could say what alteration the pattern would require, I should want to know how it moulds at present.—J. H.

[57187.]—**Repairing Marble Ornament.**—The usual way to separate marble put together with plaster of Paris, is to carefully drive a small chisel into the joint. This should be done by a person used to the job, for although a simple matter, an unskilled man would be more likely to break the article than open the joint. The gloss spoken of by "W. E." is the polish. The article will have to be repolished.—W. Potter.

[57189.]—**Income-Tax.**—The tax is levied on individuals, not on partnerships or firms. Let each partner send in a separate return, and no mistake can be made.—Os.

[57190.]—**L. B. and S. C. Railway Engines.**—No. 214, "Gladstone": Cylinders 18¼in. by 26in., cast in one piece; leaders and drivers, coupled, 6ft. 6in.; trailers 4ft. 6in., grate area 20·6 sq. feet, tubes, 331 in number, 10ft. 8¼in. long, 1½in. diameter; heating surface of tubes 1,873 sq. ft., of firebox 112½ sq. ft., wheel-base 15ft. 7in., weight in steam 38 tons 14 cwt. No. 605, G.E.R.: Cylinders, 18in. by 24in., bogie and trailing wheels 4ft., drivers 7ft. 6in., grate area 17·1 sq. ft., tubes, 203 in number, 11ft. 8in. long, 1⅝in. diameter, heating surface of tubes, 1,097 sq. ft., of firebox 111 sq. ft., wheel-base 23ft. 1in., weight in steam 42¾ tons. "Lord of the Isles," G.W.R., broad gauge, as originally built 35 years ago: Cylinders 18in. by 24in., carrying wheels 4ft. 6in., drivers 8ft., grate area 21 sq. ft., tubes, 305 in number, 2in. diameter, heating surface of tubes 1,799 sq. ft., of firebox 153 sq. ft., weight in steam 35 tons.—W. B. P.

[57190.] — **L. B. and S. C. R. Engines.** — "Piston Rod" will find full particulars of Mr. Stroudley's front-coupled express "Gladstone" in a number of the "E.M." issued about a year since, while the bogie single engines designed by the late Mr. Massey Bromley for the G. E. R. were described in these pages but a very short time since. However, I believe that the third on the list, the G.W.R. broad-gauge express, has not been mentioned for some considerable time, so the chief dimensions are at "Piston Rod's" service:—Total weight, 41tons 8cwt., distributed as follows—four leading wheels, 15 tons 18cwt.; drivers, 16tons; and trailers, 9tons 10cwt. Cylinders, 18in. diameter, 24in. stroke. Boiler: length, 11ft. 3in.; inside diameter, 4ft. 6in. Height of centre from rail, 7ft. 7in.; 305 tubes, diameter, 2in.; length, 11ft. 3in. (?). Heating surface: firebox, 153; tubes, 1,799; total, 1,952 sq. ft. The grate area is 21 sq. ft., and the boiler pressure 140lb. to the sq. in. Diameter of driving wheels, 8ft., carrying ditto, 4ft. 6in; wheel base, 4ft. 10½in. by 6ft. 4in. by 7ft. 5in. from leading to trailing axles, giving a total of 18ft. 7½in. Length of framing, 24ft. 8½in. The tender weighs 15 tons 10cwt., and carries 2,700 gallons of water. These engines have been almost entirely rebuilt; but I fancy that no material change has been made in the dimensions.—St. Aubyn's.

[57190.]—**L.B. and S.C. Engines.**—I inclose a table of the dimensions of the "Gladstone":—Cylinders, 18¼in. by 26in.; driving wheels, 6ft. 6in.; leading, 6ft. 6in.; trailing, 4ft. 6in.; total wheel base, 15ft. 7in.; total length (engine and tender), 51ft. 10in.; firegrate area, 1,500 sq. ft.; No. of tubes, 331; total weight (engine and tender), 66tons 1cwt.; total gallons in tank, 2,250. The "Gladstone" (No. 214, 1882, Brighton Works), is an express loco on L.B.S.C.R. It has a great many peculiarities. The chief one is the use of such large wheels coupled in front for express passenger traffic. It was thought by many well-known loco superintendents to be dangerous; but there is no reason why it should be so. The chief opinions against it were that large wheels were more likely to mount the rails than small ones. Mr. Stroudley has used as large wheels for some time. In 1877 he designed some engines, cylinders 17¼in. by 26in., 4ft. coupled in front, 6ft. 6in. wheels. These engines are very neat, and capable of doing heavy work at moderate speeds (on a bad road). In proof of what I have mentioned, Mr. Stroudley has never had a single accident as regards the coupling of large wheels in front (such as mounting the rails, &c.) The weight of these locos in working order is 36 tons. Another peculiarity is the boiler, which has great heating surface in proportion to its size. The tubes are not only small, but very closely set; they are 331 in number, 1½in. in diam., and 10ft. 8½in. long. They are made of steel. To work this boiler properly great precautions have to be taken as regards the feed water. It is very well known that when water is heated it throws down lime-salts, &c. Mr. Stroudley has for many years heated the feed water by turning a portion of the exhaust steam into the tank, and does so in this loco. The line from London to Brighton is heavy (compared with 60 miles out on the G.W.R., L.N.W.R., M.R.) The chief gradient which appears is 1 in 264 and 1 in 100 for 2½ miles per New Cross. The trains on the L.B.S.C.R. have been getting heavier and heavier every year, and now the City express from Brighton to London Bridge, leaving at 8.45 a.m., weighs 350 tons (engine and tender included). To convey this in one hour and five minutes is difficult work, on account of the gradients. To feed the boiler, as the feed is heated, pumps, and not injectors, are used. The pumps Mr. Stroudley uses are of peculiar construction: they have three inlet and three outlet valves, and an air chamber placed close over the outlet valves. Two small valves are provided on the suction pipe, which take in air at every stroke, and so soften the working of the pumps and keep the air-vessels supplied. When the water in the tender gets very low and very hot, these valves do not work, and a small cock is provided on the Westinghouse main pipe, by which the driver can allow air to escape into the pump, thus keeping it perfectly quiet, as when the water is colder, engines fitted with pumps alone are liable to get into trouble if they have to stop for any length of time with a heavy fire on, and no means existing of getting water into the boiler; so Mr. Stroudley has placed an auxiliary feed-pump under the Westinghouse pump, and has provided a valve by which air is allowed to circulate in the air-pump without being forced into the receiver. The Westinghouse engine being then put in motion, it will feed the boiler at a rate sufficient to preserve it from all risk while the engine is standing still. The arrangement of the reversing gear is very ingenious. The reversing wheel and screw can be worked by hand; but the compressed air from the Westinghouse reservoir is employed to do the heavy work. A small cylinder, 4½in. diam., is fitted with a piston and rod attached to the nut of the reversing screw, and a small cock allows air from the Westinghouse main reservoir to pass in behind the piston. This forces the engine into back gear, and the screw has merely to be used to regulate the movement. By allowing the air to escape, the weight of the valve motion puts it into forward gear. There are no balance weights. There are many other features on this engine which are common to many of Mr. Stroudley's engines—viz., the electric bell in communication with the guard, the duplicate gauge glasses, the two pressure-gauge glasses, with two hands each (one gauge for the steam), one of its hands tells the boiler, and the other the steam-chest pressure; the other gauge is for the Westinghouse brake (one of its hands tells the reservoir, and the other the train-pipe pressure), and speed indicator. Mr. Stroudley places the outside cranks in a line with the inside ones (and not opposite, as they usually are). The piston rod and crosshead are in one forging of steel. The motion plate is of cast steel, and the guides for the valve rods are cast with it. The tender has inside bearings to match the engine. They are oiled from the top of the coping, access to which is obtained by walking along the foot-plate. Thus all risk of men leaning over to oil the boxes, and being knocked off by bridges, &c., is done away with. I must now apologise for filling up so much of your space, but trust this may be of use to your readers. The Granville, Northcote, and Salisbury are of the same dimensions, &c., as the Gladstone, and two more are being made.—A. A. C.

(Martin's screw-cutting tables.)—R. N.

[57195.]—**Iron Rusting.**—Try white lead and tallow applied hot. This is easily removed.—Os.

[57195.]—**Iron Rusting.**—Linseed oil is sometimes used; but Buck and Hickman, the tool makers, employ a special transparent preparation, which would answer the requirements of the querist.—Bacchus.

[57204.]—**Sea-Water Aquarium.**—1. Sea-anemones are about the easiest things to keep. The common sort, *Actinia mesembryanthemum*, lives best. The "Plumose" (*S. dianthus*) are lovely creatures and live very happily; so do the "Daisies" (*Sagartia bellis*). Almost any sort except the "Dahlia Warttet," which requires more water than it is possible to allow it. For fishes the blennies and gobies are decidedly best; eels live very well (I have had one for two years), but are seldom seen, so don't do much good. For plants you ought only to have two sorts if you want to get on well; one is the "Sea lettuce" (*Ulva latissima*), and the other *Enteromorpha*. 2. You *can* keep the water for five years without changing; but in order to do so you must have very few animals in proportion to the volume of water, and keep the aquarium in a very dark place. I prefer myself to keep it in a place where one can *see* the creatures, and change the water pretty often. You needn't have real sea-water; but you can use Southall's aquarium sea-salt, which answers just as well. 3. There is not the slightest occasion for any zinc top, unless you want to prevent fishes from jumping out. 4. Any place will do to keep it in. I should recommend your dining-room window, or if you prefer it the hall; *not* in a conservatory. Now for useful hints. You must not let the sun shine on it too much; in the winter it does not matter, but in summer it must be covered up. Don't leave any scraps of meat (with which the creatures ought to be fed) in the water, or they will ruin the whole business. If the water looks muddy sometimes, syringe it with a glass syringe till it becomes clear. The anemones enjoy this process, and open wide generally while it is carried on. All the skins (which the anemones have a habit of casting) must be taken out as soon as discovered with a small net. More advice if you get into difficulties.—R. A. R. Bennett, Walton Manor Lodge, Oxford.

[57206.]—**Legal.**—If you did absolutely buy the ground, you can compel him to complete the sale; or if the value has increased, you can sue him for the difference by way of damages. The only question is, Did he stipulate for any particular sort of house? If he did not, of course, you can do as you like. Tender him the remainder of the money and take possession of the ground. If it has increased in value, of course, he will be glad to get it back, as he can get more money from someone else.—Os.

## UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

**The Whitworth Scholarships, 1885.**—The following is the list of successful candidates for the Whitworth Scholarships this year:—Thomas Clarkson, 20, engineer, Manchester, £200; Hugh O. Bennie, 20, engineer, Glasgow, £150; Robert H. Unsworth, 20, engineer, Pendleton, near Manchester, £150; Harold M. Martin, 21, engineer, Gateshead, £150; William T. Calderwood, 25, mechanical draughtsman, Glasgow, £150; John Richards, 22, blacksmith, Cardiff, £150; Ernest R. Dolby, 23, engineer, Leeds, £150; James Rorison, 21, engine fitter, Paisley, £150; Arthur J. Moulton, 20, engineer apprentice, Preston, £150; William McNeill, 22, mechanic, Birmingham, £100; George W. Moreton, 24, fitter, Crewe, £100; Stephen E. Mallinson, 24, assistant analyst, London, £100; Henry C. Jenkins, 23, engineer and millwright, London, £100; Robert Smith, 24, engineer, Glasgow, £100; Thomas W. Nash, 21, engineer, London, £100; Henry F. W. Burstall, 19, engineer apprentice, London, £100; Arthur J. Stopher, 22, mechanical engineer, Nottingham, £100; Sidney H. Wells, 19, marine engineer apprentice, London, £100; George Milnes, 24, fitter, Charlton, Kent, £100; Henry Begbey, 22, engineer, Old Charlton, Kent, £100; John Goodman, 23, engineer, Brighton, £100; Mark H. Crummie, 21, mechanical engineer, Hull, £100; Oliver Marsh, 22, fitter and turner, Crewe, £100; Thomas Galbraith, 23, pattern maker, Manchester, £100; Joseph H. Bowles, 23, engine fitter, Stratford, £100.—Calderwood and Richards were bracketed equal.

**New Fire-Alarm.**—With reference to Mr. Pritchett's electric fire-alarm, illustrated on page 495, we are informed that Messrs. J. T. Mayfield and Co., of 41, Queen Victoria-street, E.C., are the sole makers, and will be glad to show the instrument in action at any time at their show-rooms, 35a, Queen Victoria-street.

## QUERIES.

[57207.]—**Electric Lamp.**—I have got one of Swan's incandescent lamps. How am I to tell the number of c.p., as it is not marked?—it cost 5s. about three years ago.—Plumber.

[57208.]—**Speaking Tubes.**—Can any reader of this paper who has had experience in fixing long-distance speaking tubes, say if there is any difficulty in communicating through 300ft. of 1½in. lead pipe? I might say I shall have about six corners to turn.—J. B.

[57209.]—**Case-hardened Iron.**—Will any fellow-reader kindly let me know how I can case-harden iron studs in an ordinary smith's fire? What are the compounds, and how used?—Busby.

[57210.]—**Tar.**—To Mr. Allen and Others.—Stockholm tar, which is obtainable from trees, is of a brown colour; coal tar, which is of vegetable origin, is intensely black; this change in colour is effected by nature. What is the process? I wish, by copying nature, to turn Stockholm tar black, if this be possible.—Dandie Dinmont.

[57211.]—**Steam Launch.**—I want to build two of the above, suitable for single-cylinder engines, cylinders 5in. diameter, 6in. stroke; boiler, 4ft. 8in. long, by 2ft. 9in. diameter; fitted with 52 1¾in. tubes. Can any of "ours" give me the name of any work that would give me idea of best mould and size for such engine and boiler?—Carpenter.

[57212.]—**Co-ordinate Geometry.**—Would any of your readers be kind enough to inform me when the sectorial angle and radius vector are considered positive, and when negative? Also if the rectangular co-ordinates of A be 4, 4; of B 3, − 8, of C − 2, − 7, find the sines, cosines, and tangents of angle between the lines joining A and B, A and C.—E. S. L.

[57213.]—**Hydrostatics.**—I should be grateful if any reader of the "E. M." would give me the working necessary to solve the following:—If the surface of a detached sheet of ice, whose sp. gr. is 92, floats ½in. out of water; find the thickness of the ice?—Private Student.

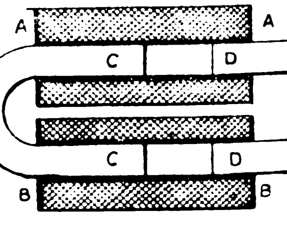
[57214.]—**Electric Bell.**—Will some kind reader of this valuable work inform me how much, and what size wire I should require for two iron cores, 3-16in. diameter, 1in. long, to work a 2in. gong, and oblige.—A Constant Reader.

[57215.]—**A Pottery Furnace for Experimental Work.**—Can any reader of the "E.M." give drawings and working details of a small furnace, suited for experiments on glazing and enamels, the total height being about 6ft. Such a furnace would be of value to many readers.—B. L. Pearson.

[57216.]—**Wheatstone Bridge.**—Will any one kindly give me a sketch of the connections in Messrs. Elliott Bros. new platinum rheostat, and say whether the 1-20ohms are added together, when the plugs are out as in the units?—H. S. H.

[57217.]—**Taxidermy.**—Can any reader of the "E.M." help me out of a difficulty? In preserving fresh-water fish, I fail to keep their colour; roach and bream for instance, turn dark, thereby losing their beauty! I use size made from parchment cuttings, applied hot.—Young Beginner.

[57218.]—**Electro-Magnetic Problem.**—Will any of your readers kindly work out the following problem, and show how it is done? A and B are two coils 24 centimètres long, each having 4,000 turns of covered copper wire, 1mm. diameter, amounting to 1,000 mètres. A horseshoe magnet of round soft iron, 36mm. diameter C, is fixed with its poles halfway into the two coils; a similar horseshoe magnet D is free to move into the other ends of the coils. What is the current in volts and ampères required to magnetise C to saturation (intensity of magnetic field 45)? Also what is the force in grammes exerted on each pole of the free magnet, when the distances between the poles of the two magnets are respectively 12, 9, 6, 3, 0, centimètres? Also is the current affected by the position of the free magnet when at rest?—Asterisk.



[57219.]—**Screw Cutting.**—Will any of my fellow-readers let me know if a screw chaser can be made from an ordinary tap, and how it is done, and if they can give me a table of the different wheels to put on the mandrel and the stud to produce the different number of threads per inch on a leading screw of four threads per inch?—Busby.

[57220.]—**Batteries.**—I am about to place a series of six gravity batteries in my laboratory. Will some correspondent describe the best method, also the correct method of attaching wires, &c.? I am getting the cells from London, and wish to know how to set them up for operation?—Western Youth.

[57221.]—**To Mr. Bottone.**—Please give me brief drawings of the ironwork of a Gramme dynamo, to light about 100 candle-power, also the amount of wire and sizes of same?—W. P. W.

[57222.]—**Lecture Illustration.**—I want to illustrate my lessons, given to a class of about 50 students, by means of the lantern and slides. The slides are photos taken from prints. I want information (1) Do mechanical subjects show up well on the screen? (2) What apparatus would be suitable, *i.e.*, for taking the photographs, and for projecting on screen? Would Lancaster's quarter-plate Instantograph be good enough for taking the photos?—KIPPO.

[57223.]—**Gas-Engine.**—To "INVICTA."—I made a gas-engine, 3¼in. bore, 6in. stroke, 2in. compressing chamber, explosion every second stroke, I ignite it with a red-hot pipe. I had many very good explosions, and had it running for three minutes, but cannot get it to run properly. Please will you state if it is really too little to make it work properly, and which is the smallest compressing engine working?—G. J.

[57224.]—**Prevention of Noise.**—The Scotch system of building houses in flats may have its advantages, but it has also its disadvantages, as I have found to my cost. I have just purchased a lathe and I also amuse myself with joiner work; but I am afraid I will have to stop these amusements, as the family beneath have sent up word that the noise is too great to be borne. I shall feel truly thankful if some of your correspondents can put me in the way to prevent the noise from travelling downwards.—SPES.

[57225.]—**Copper Bend.**—To "GLATTON."—It was not a band I inquired about, but a bend made in two halves, with seams at the side, say for a 4in. pipe. If "Glatton" can give me any hints how to make one I shall feel obliged? I thank him for the definite reply he has given me recently to my other query.—PLATE WORKER.

[57226.]—**5ft. Reflector.**—In a telescope whose 4½in. speculum is of 60in. focus, how far from the speculum must the 1in. plane mirror be placed? In a small book I have, the position of plane is given as "half the diameter of the tube from the principal focus," thus bringing the focus exactly in the opening in the side. Would not this be too near the small mirror to allow the use of negative eyepieces or a Barlow lens?—A. B. C.

[57227.]—**Cleaning Sextant.**—Would any fellow reader kindly say how I can clean or remove green scale or verdigris on sextant? It has not been in use for a year or two, and seems difficult to remove unless by dipping in acid, and that, of course removes the black varnish or skin. The green, of course, is the result of salt water. —BILL.

[57228.]—**Tinman's Piecework Prices.**—Can any reader inform me if there are any such published, or if I could obtain a list, either for London or Birmingham?—PLATE WORKER.

[57229.]—**Gold and the Mint.**—I am given to understand that the Mint Authorities are purchasers of gold. Do they buy it if of low quality, and would there be much risk in sending them a parcel from the country? To whom should such parcel be addressed? Do they charge for melting and assaying?—WESTERN.

[57230.]—**Cardew's Voltmeter.**—I wish to test E.M.F. of a Siemens D$^3$ (6,000c.) upright machine with above. Will some reader of "Ours" kindly say if entire current from dynamo should be passed through voltmeter, or should it be connected in a shunt circuit, and how? The voltmeter, with extra resistance, reads to 150 volts. The dynamo shows a current of about 34 ampères when tested with a Siemens dynamometer.—DON'T KNOW.

[57231.]—**A Six-Footed Pig.**—A friend of mine has a pig with six feet, the two extra ones branching off from the fetlock of the fore leg; they are fully developed. When the pig is killed I want to keep those feet, and I shall feel obliged if some correspondent will kindly tell me how I can preserve them?—C. D.

[57232.]—**Heating by Steam.**—Would some kind friend answer the following?—Wishing to heat a large building, 70ft. by 30ft., by steam-pipes, could we take steam from a Cornish boiler at any pressure, from 10lb. to 50lb., round the building, and bring the condensed water back into the same boiler by a small back-pressure valve at the front of the boiler? Or could we take the exhaust steam from a horizontal engine, with cylinder 11in. diameter by 24in., round the building and back into a well during the day, but would have to take steam from the boiler during the night? The exhaust pipe from the engine is 3in. diameter. As it would be a great distance round the building, would it be liable to increase the back pressure on the piston of the engine? Please give information as to size of pipes?—A. D.

[57233.]—**Fret Saw.**—Will any of "ours" kindly give me a few tips in the making of the above, which I would like to be worked by treadle? I am anxious to make it of wood, or at least as much of it as is possible. The fuller the details in the advice the better. What book on fret working and kindred woodworking would you advise an amateur to go in for? What ready-made fret machine of a reasonable price would be the best to buy?—JOB.

[57234.]—**Colour Lakes.**—Will "An Analytical Chemist," or some other chemical friend, kindly give a list of modern transparent colours, suitable for oil varnish in the same sense as red alkanet colour is transparent in oil?—T. WOOD.

[57235.]—**Thermometer.**—Will any of our scientific friends kindly inform me if we have at command, any thermometer or indicator of momentary changes of heat in vapour, &c., more sensitive and more convenient to read, than the clinical thermometer? I want to read the temperature of air, as it goes in and comes out of the human system.—T. WOOD.

[57236.]—**Adhesive Paste.**—Any hints on preparing a good adhesive paste for labels, &c., not to mould, same as "Gloy," would greatly oblige an old reader of "Ours." —A. W. G.

[57237.]—**Grooves of Pulleys.**—Could any of your readers give me a rule or method for cutting out the grooves in a pair of grooved gut pulleys, so that when the speed was changed, the band might always be tight—of course that is when the one has a greater diameter than the other?—BORDERER.

[57238.]—**Vacuum Tube Rotator.**—Could any friend of amateurs give instructions as to making a vacuum tube rotator, to work electrically?—W. P. W.

[57239.]—**Coil Regulator.**—Could any kind reader tell me how to make a regulator for regulating the power of shocks from a ¼in. spark coil?—W. P. W.

[57240.]—**Automatic Musical Instrument.**—I have obtained a copy of Mr. Wenham's specification, No. 5024, 1884. Theoretically the whole thing is apparently simple and clear but is it practically successful?—is it equal in effect, to say, the pianista? I opine from Mr. Wenham's description in No. 1061 (24516), that he has actually constructed one or more, and looking at the date of the complete specification, Nov., 1884, why is it not exhibited at the Inventions Exhibition, and shown in action? Perhaps Mr. Wenham will kindly answer these questions, and say where the instrument can be seen and heard.—B.

[57241.] — **Robinson's Patent Lubricating Bags.**—A patent has just been brought out in the shape of a lubricating bag. It is made of canvas and filled with the lubricant, which is a grease capable of becoming semi-liquid when coming into contact with heat. The bag is placed upon the bearing of plate rolls, or axles, &c., and as the bearing becomes heated by friction the grease leaks through the pores of the bag, and so lubricates the bearing. What I want is some one to tell me how to fill the bags quickly? The present mode of filling them is by hand, on the same principle as sausage making; that is to say, by putting the grease into a cylinder and forcing through a pipe into the bag. This is a very slow way of doing it, as the bags have to be cut the required size and then sewn; then the lubricant is put in the bag, and the hole left to fill the bag has to be sewn up, thus taking up a great deal of time and labour, which, I think, might be dispensed with in some way or other. I should be glad if "Invicta," or some other friend would enlighten me on the subject.—H. U.

[57242.]—**Chemical.**—To MR. GREY, F.C.S.—I propose studying the composition of Portland cement. Would you be kind enough to draw up a table or recommend a practical book, to include the quantitative estimation?—DAVID STEPHEN, Wellington Quay.

[57243.]—**Condenser.**—Will any of your readers kindly help me in making a good condenser for an engine of 8in. bore, 15in. stroke, to run at about 165 to 175 revolutions per minute, with the boiler pressure from 65 to 70lb. I have plenty of water, the river is a foot from engine. Will I get much power from it? A sketch, and size of condenser will oblige—F. A. M.

[57244.]—**Dentistry.**—Will some kind reader explain where I can get the necessary tools for making false teeth? Is the vulcanising process supposed to be better than plate work? Can a brother mechanic give a sketch of how to make a cheap vulcaniser? I wish to perfect myself in dentistry, and any hints as to books or classes would be gladly received.—MECHANIC.

[57245.]—**Compound Tandem Engines.**—Will "Invicta" kindly give a sketch and dimensions of a pair of compound tandem engines with outside pipe condenser, suitable for a boat about, say, 20ft. by 5ft., showing arrangement of valves and air pump?—R. N.

[57246.]—**Boiler.**—I have a steam boiler, and I want to know what pressure it will stand for working: size, 12½in. high by 6in. diameter, with firebox 5in. diameter by 6in. high, with 2¾in. brass tube carried up, all made of brass 1-16in. thick all over, and riveted vertically twice, and well riveted all round and inside, and soldered; water space all round ½in. Can anyone say if it will stand 100lb. working, and actual pressure, and how it is got at?—FERROTYPE.

[57247.]—**Tempering Twist Drills.**—Will any kind reader oblige by informing me how to temper twist drills and reamers? Also the best material to use for grinding steam and water-cocks?—W. THOMSON, Sukkur, Scinde.

[57248.]—**Speed of Launch.**—To "INVICTA" OR OTHERS.—In a small steam launch, say of 10ft. length, the paddles revolving 200 per minute, a speed of eight miles per hour is obtained. If the speed of the paddles be increased to 2,000 revolutions per minute, would there be any increase in speed, and if so, in what proportion? Also, what is the average number of revolutions of the screw propeller in small launches, and would an increase in the number of revolutions in the screw give greater results in speed than in the case of paddles, or would the water be churned into foam? I may say that if the speed of boat increased at all in proportion to the number of revolutions of propeller, I could obtain easily 5,000 per minute from a rotary engine of a new design, which has registered as many as 16,800 at 30lb. pressure, and which has the advantage of lightness, a 4½-h.p. only weighing (without flywheel) about 20lb.—SENSITIVE FUSE.

[57249.]—**Electro-Motor.**—I must apologise to Mr. Eugene Brown and Mr. S. Bottone for not clearly stating what I wished to do with my motor. I have a shunt-wound motor which I wish to be able to run in either direction, so I use two phosphor bronze plates as brushes touching the commutator tangentially. I can by this means reverse the direction of rotation by simply altering the direction of the current through the armature only, the brushes being always in the same position. What I want to know is whether, when the machine is running at full speed, I can reverse the direction of the current in the armature, and so the direction of the rotation of the machine, without damaging the machine in any way.—W. E. H.

[57250.]—**Coke Cracker.**—Will someone tell me how to make a simple one of above, for hand or power, of the simplest possible construction?—and greatly oblige—P. W. R.

[57251.]—**Agglomerate Blocks.**—A short time ago I made an oblong box, partitioned so as to form an electric battery of three cells. Having purchased three agglomerate blocks of the Leclanché pattern, I joined the cells in series and set them to work with bells, &c. In about four days two of the carbon sets fell to ashes, the remaining one is working by itself all right up to the present. The chemicals employed are common salt and water, same proportion as sal-ammoniac. If any of your readers would be good enough to say if I am right in supposing the carbons are not good, I would be much obliged.—F. E. MORGAN.

[57252.]—**Free Reeds.**—Many thanks to G. Fryer and "G. L. B." for their kind information respecting my query, but what I wanted was (I must say with all due respect to both Mr. F. and "G. L. B.") instructions how to make a tuning apparatus, and I will be much obliged to either for a sketch of the apparatus as used in organ factories? As to my private correspondence with Mr. F., I wish to say that I did intimate to him that I was not a competent tuner, and intended to purchase a chromatic scale of reeds, tuned to equal temperament, as a guide, but I fell out of work just at that time, which has prevented me from getting them. I thought it very ungentlemanly and against the rules of this valuable paper to mention my correspondence in the way he did, as I have spent most of my leisure hours for the last twelve months in learning how to tune reeds, unassisted by any practical tuner, and don't mean to give it up now. I have a good ear, and I don't see why I should not succeed with practice. I have got very valuable information from back vols. of the "E.M.," especially Vol. XXIII. on tuning. I believe if I could get two hours a day with a practical tuner for a week, it would about set me right; but as I cannot get it, I shall have to do the best I can. In conclusion, I wish to ask a few questions on tuning: 1st, In tuning or laying the bearings by fifths and octaves of a reed instrument, equal temperament, is it a rule to have all the fifths a slow wave flat? 2nd, What is the exact speed of wave, and is it to be the same speed in all the fifth intervals throughout the scales? 3rd, Is it right to tune fifths and octaves by a light pressure of wind? 4th, Why does a reed sound flatter in an instrument than out?—AMATEUR TUNER.

[57253.]—**Waterwheel.**—To "INVICTA."—Is 20lb. water pressure, from a pipe ⅜in. internal diameter, sufficient to drive a waterwheel to give 1-10h.p.? If so, I should esteem it a great favour if you would give me a sketch and dimensions of such a wheel, also any hints as to construction will oblige? There is no such thing described in any back numbers I have.—ROUGE GORGE.

[57254.]—**Photo. Chemigraphy.**—In a back number it states that the zinc plate for this process is to be coated mith a mixture of gum-arabic, water, grape sugar, bichromate of potassium, and a few drops of ammonia, and afterwards to be etched with strong solution of ferric perchloride. Will someone kindly give the actual formula, as the above directions are very vague?—GRATEGOSH.

[57255.]—**Storage Battery.**—I am about to make a storage battery of two cells each of eleven plates connected alternately. Will "Bunsen" or any other person kindly tell me (1) The best plan to keep the plates in position, and from contact? (2) How I am to tell when they are fully charged? (3) How many times before formation is completed? (4) How many 10 or 20c.p. Swan lamps it will light;—size of plates 5in. by 5in.?—W. LAURIE.

[57256.]—**Fees to Fire Brigade.**—What are the rules or by-laws referring to fees or expenses payable to the Metropolitan Fire Brigade? Is it true that if an engine arrives, or any fireman enters a house where there has been a slight fire, although now extinguished, the householder has to pay a certain considerable sum, which can be enforced by law?—FIRE.

[57257.]—**Equatorial Mounting.**—Can any of our astronomical readers refer me to a description sufficient to work from, of a simple, yet effectual, form of equatorial mounting, suitable for a 3in. refractor? It must not be too difficult to make. I have no doubt in some back number of the "E. M." there is such a description, but not very recently, and if I knew in which, could get it from the office.—LANDBIRD.

[57258.]—**Chemical.**—Would any of our chemical readers give some reliable method for the detection and separation of a mixture of not more than two acids and bases, to be selected from any of the following salts:—Benzoic, succinic, salicylic, citric, tartaric, oxalic, hydrocyanic, formic, and acetic acids, as required in the Advanced stage of practical organic chemistry, under the Science and Art Department, and oblige.—ORGANIC STUDENT.

[57259.]—**Making Patterns on Glass.**—Will some kind reader inform me how I can take patterns from prints, drawings, &c., and transfer, print, or draw them on glass? I saw the other day a magic lantern slide, which had the appearance of a steel-plate engraving, every line showing so plainly. Will some reader tell me how this was done, or any other information on making patterns on glass? I might say I don't want them to stand any length of time.—R. H. C.

[57260.]—**Flies.**—Will someone kindly say where there is a good account of the life-history of the common house-fly?—T. W.

[57261.]—**Cupola.**—Is it possible to build a furnace to melt about 12lb.? Would the pull of a chimney 40ft. do? I have experienced difficulty in getting good castings, and think ironfounders don't care about small jobs, and no doubt many of our readers think the same. I believe iron that has only been melted once turns out soft; is that so?—and is the hard stuff we often get hold of through old iron or the loam? If anyone could give a few hints, I should be very much obliged.—J. K.

[57262.]—**Quick-Drying Paints.**—I have lately made experiments with quick-drying paints, and have used spirits of wine and shellac? Can you recommend me any other varnish, equally good and cheap?—R. J. P.

[57263.]—**Chemical Action in Battery.**—What chemical action takes place in a battery of zinc and carbon with chloride of ammonium, also in one where manganese is used?—R. J. P.

[57264.]—**Blue Paint.**—Wanted, a good cerulean blue paint which will stand a good heat without blistering, turning black, or yet fading.—R. J. P.

[57265.]—**Bees.**—Having a large and light spare room in house, I propose keeping bees; will it be safe? Any information suitable for a beginner will be thankfully received.—R. PARKS.

[57266.]—**Sea Voyage.**—On account of ill-health, I have been advised to take a sea voyage. Can any brother reader inform me if it is possible to work, or partly work, a passage to Australia and back, as steward's or purser's assistant, or some similar capacity (age nearly 22) ?—Five Years' Sub.

[57267.]—**Live Spindle.**—Some months back a correspondent stated where in London, he had got small lengths of hydraulic tube, about ⅜in. outside diameter, suitable for live spindle. Will anyone kindly repeat the information, or state what number of "E. M." it appeared in ?—Dubious.

[57268.]—**Dyeing Fishing Baits.**—Will any of our readers (deep-sea fishers), inform me what is the best yellow to dye feathers with ? I have tried various dyes, but can't get them to stand the salt water. I would much rather have natural yellow feathers, if anyone could inform me where I could get them ; I have tried all places that were likely to have them, but could get none.—Joiner.

[57269.]—**Phosphorescence of Sea.**—I shall be obliged by some correspondent kindly explaining the cause of the phosphorescent appearance of the sea as observed in the following manner ? I was crossing the Channel by the 8 p.m. boat from Boulogne to Folkestone on July 9th, and when it became dark enough, about half past nine perhaps, noticed this condition which continued unaltered till the boat stopped in Folkestone Harbour. It did not cover the surface generally, but was evidently excited by the motion of the boat ; the phosphorescent parts being only the foam and crests of the waves thus produced, and consequently especially marked was it in the neighbourhood of the screw. It was well seen even in the smooth water of the harbour, and where the water was reflected from the wooden piers of the landing-stage it showed very beautifully. Seen in this way and so close to the shore, it occurred to me that the usual explanations of marine phosphorescence, viz., that it is due to certain animal organisms of peculiar species would hardly apply. Although new to me, not being aquatic in my habits, it is doubtless familiar enough to many others, and I should be pleased to learn the cause of the condition as thus seen ?—Landbird.

[57270.]—**30-Lighter Dynamo.**—Will "W. H. E." kindly inform me what current, and at what potential, his machine will work ; also, what speed to be given to armature ? I require it wound for 50 volts ; perhaps "W. H. E." will give me wire required, unless he has worked above for his potential.—Volta.

[57271.]—**Flageolet Tuning.**—Will some reader kindly inform me how to tune the French flageolet ?—R. E. H.

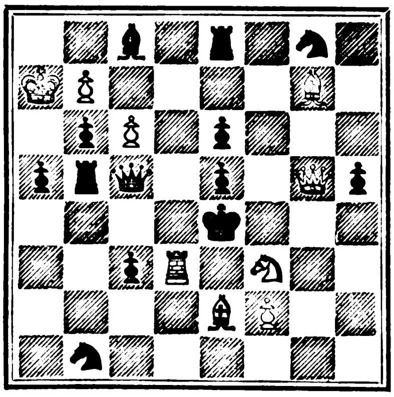
## CHESS.

◆

All Communications for this department must be addressed to J. Pierce, Langley House, Dorking.

PROBLEM DCCCCLII—"Patience."

*Black.*



*White.* [9+13

White to play and mate in three moves.

Solution to 949.

| *White.* | *Black.* |
|---|---|
| 1. Q-Kt sq | 1. Q-B 6 (a) |
| 2. Kt-R 6 | 2. Anything |
| 3. Q or R mates | |
| 2. K-R sq, &c. | (a) 1. Q-R 2 (b) |
| 2. Kt-B 2, &c. | (b) 1. P-Q 7 (c) |
| 2. Kt takes Kt, &c. | (c) 1. Kt-K 6 |

### NOTICES TO CORRESPONDENTS.

Correct solutions to 950 by E. S., B. Fison, Rev. W. Anderson (Old Romney), F. O'N. H. (a puzzle-headed conception, rather than a problem), R. A. Bennett, A. S. Olver (pitfalls). A. A. E. Lecluse (key move apparent, too many duals) and H. Culmer.

To 951 by E. S , R. A. Bennett (very neat), V. S. Pochin, H. Culmer, Streetgate, and A. S. Olver (don't like it).

To 949 by T. L. Robins.

E. S.—Notice was repeatedly given at the beginning of the tourney, that if solvers wished to score full marks, they must send full solutions, both of the two and three movers. The reason such are not printed is because of the space they would occupy.

B. F., V. S. Pochin, and A. A. E. Lecluse.—If in 950, 1. Kt-R 6, 1. Kt-K 6, 2. Q takes R P (ch), Kt-Kt 5 (ch).

T. L. Robins.—Your solution to 950 appears to fail if Black play 1. Kt-K 6. See notice below to Streetgate.

V. S. P.—You have overlooked in 949 that Black can check with R at Q Kt 3. We did not receive your solution to 948.

Streetgate.—The solution you sent was quite correct : the initials referred to another correspondent. Your elaborate solution of 950 appears to fail in this variation, 1. P-K 6, Kt-K 6 ; 2. Kt takes Kt, Q-Q R 4. And where is the mate ?

W. A. (Old Romney).—We will try to examine some of the problems without further delay ; but will you be kind enough to send the solutions given in the English Mechanic ?

## ANSWERS TO CORRESPONDENTS.

⁂ *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

### HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Aug. 12th, and unacknowledged elsewhere :—

G. E. Davies.—Rev. T. Calliphronas.—J. and H. Grace.—R. E. Phillips.—Gilford.—Mills Reading Society.—E. N. Grimwade.—F. H. Briggs.—R. R. R.—One in a Fix.—Pedlier.—W. H.—Transit.—C. R. K.—C. A. W.—J. Brierley.—Pump Patent.—George Smith.—G. Park. J. T. Strange.—S. Bottone.—J. E. Gore.—A. Evans.—Rev. J. Pearson.

F. G. Williams, Demerara. (The late Government was defeated by the united efforts of the Conservatives and the Irish party. It was, of course, in Mr. Gladstone's power to have advised the Queen to dissolve Parliament, and appeal to the country. Then, if the country had returned another Liberal majority, Mr. Gladstone would have resumed power. But he declined to take this course, because it would have been foolish to appeal to the present limited electorate, when so many more voters will be added to the register at the General Election, which must take place shortly. The Queen, therefore, sent for Lord Salisbury, and that statesman formed a Ministry, which retains power in the face of a Liberal majority by a sort of tacit understanding between the two parties that he shall be allowed to do so until the General Election determines which party the people really wish to take office. We cannot deal at length with political questions in these columns, and should recommend you to take in the *Weekly Times*, published at this office, which is the best English Liberal weekly newspaper, and in the columns of which we shall be glad, from time to time, to solve any difficulties that may occur to you in connection with social and political subjects.)—Trophy. (We cannot spare space for five problems a week.)—J. G. B. Yates. (We incline to your opinion that they were not cheques, but simply requests to pay ; but the question would admit of argument on the facts.)—Ebbw Vale. (You would gain the most useful information in connection with villa and cottage building by searching the volumes of the *Building News* ; but if you consult the Catalogue issued by Mr. Calvert, of Great Jackson-street, Manchester, you will find a list of books from which you can make your choice.)—J. Johnson. (The book that will apparently suit you is "Tall Chimney Construction," by R. M. and F. J. Bancroft, just published by John Calvert, Great Jackson-street, Manchester.)—A., Liverpool. (We must really refer you to a textbook. Try Mr. Sprague's "Electricity." The charge makes no difference in the weight of the jar. 2. We do not know of an electro-magnet or a magnet that will attract copper, tin, and brass.)—Jumbo. (Because very few were coined in that year.)—D. R. S. (It is a monthly, published at Boston, Mass., which draws liberally on our columns without acknowledgement.)—Copyist. (See indices. It is usually a lithographic ink, but you will find recipes in back numbers.)—Young Blacksmith. (We do not know of any.)—One in Despair. (The letter on p. 456, seems to meet your case exactly ; but if not, you will find many other hints in back volumes.)—W. Chapman. (You might try a decoction of green walnut shucks.)—Geo. Fleming, Philadelphia. (The price north of the Thames is 3s. 2d. per 1,000 cubic feet ; south, 2s. 10d. We believe there is no difficulty about hiring gas-stoves, and some companies urge their customers to hire them.)—E. Knight. (The stamp on the application for a patent is £1 ; 1s. is the cost of the stamp on the declaration before a magistrate, and a few pence for the printed forms. The "three guineas" you mention must be an agent's charge. He must be paid for his work, of course, and three guineas is little enough.)—Rapier. (Form A is the "application," and bears the stamp ; form B is the provisional specification, and two copies must be sent to the office with form A. Drawings are not necessary with provisional specifications, unless requisite to properly define the nature of the invention.)—Ferrotype. (If you cannot refer to recent back numbers, procure one of the cheap handbooks, but you had better stick to the dry-plates.)—N × X Zoo. (Nos. 633, 634, 640, price, post free, 7½d. Only some of the numbers from May to December, 1879.)—Ironmonger. (Yes, when the manganese is worn out. See "Recharging Leclanché Cells," pp. 21, 42, 121, 394, Vol. XL.)—E. G. C. (Procure catalogues from Longmans and Co., Macmillan and Co., Lockwood and Co.—Enghinheiro. (You were answered on p. v. July 17, under the signature "Engineer." You do not state what branch of engineering you wish to study ; but you will have no difficulty in Glasgow in finding suitable works.)—Tintern Abbey. (It is no infringement of a patent to make the article for experiment. You will find full details for making a phonograph in Vol. XXVII. p. 157.)—Pianessamo. (If you cannot refer to back volumes, obtain Babbington's little book on tuning pianofortes from L. U. Gill, 170, Strand.)—Nautilus, Gibraltar. (The Boyton dress was illustrated in No. 534 ; but we do not know where it can be obtained. It was made of indiarubber cloth, with air pockets so that it could be inflated.)—F. J. Stevens. (Brodie and Middleton, Long-acre, publish a work of the kind ; but most books on painting contain chapters on that branch.)—A. R. (Twelve of the numbers containing the letters of Mr. Wassell to which you refer are out of print ; but there are fourteen still in stock which the publisher will send post free on receipt of 2s. 11d.)—F. M. (If you only want a few, try and get them made by those who manufacture such articles. You must make a pattern first of all, and then cast a mould from that in plaster. Then you want a core, and a vulcanising apparatus. The rubber can be made "liquid" by dissolving in carbon bisulphide ; but it will be better to use the masticated rubber mixed with sulphur and force it into shape by the aid of steam pressure, which will vulcanise at the same time.)—Engineman. (Procure Mr. Calvert's catalogue of books on practical science, which will enable you to select those suited to your pocket. The address is Great Jackson-street, Manchester.)—New Reader. (As to the bells, procure the pamphlet advertised by Gent and Co., Leicester, on our front page. As to telephones, what sort are you going to use ?)—Clerk. (Rules for ascertaining the capacity of casks will be found in many of the textbooks ; but a discussion on the subject appeared in a back volume. Hurst's formula is capacity (in imperial gallons) equal $\cdot 0014162\ L\ (Dd + M^2)$, where $Dd$ are the diameters inside at the heads, M the diameter at the bunghole, and L the length, all in inches.)—A Constant Subscriber to the "E.M." (Let your wife get a bottle of sal volatile at the chemist's, and take a teaspoonful, in a wineglassful of tepid water when the flatulence troubles her.)—C. E., M. E. (Photo-lithography is considerably cheaper than lithography, and if you are, or employ, a good draughtsman, much more satisfactory. We fancy, however, what you really want is photo-zincography ; if so, write to Messrs. Hill and Co., 46, Essex-street, Strand ; if photo-lithography, write to Mr. Jas. Akerman, 6, Queen-square, Bloomsbury ; or Messrs. Whiteman and Bass, 236, High Holborn.)

**Wood Stains in a Dry Form.**—Andres (*Erfindungen und Erfahrungen*) gives the following formulæ for some wood stains which may be put up in a dry form, and when wanted for use may be readily dissolved in water :—Oak : Five kilos. of Cassel brown brown, 0·5 kilo. of potash, and 10 kilos. of rain water, boiled together for an hour, the whole strained through a linen cloth, and the clear, dark-coloured liquid boiled to a syrupy consistency. Walnut : A decoction of Cassel brown, 3 kilos. ; potash, 0·3 kilo. ; and water, 7 kilos. ; the whole strained through linen, and during evaporation to syrup, 2·5 kilos. of extract of logwood added. Mahogany : A decoction of extract of Brazil wood, 3 kilos. ; potash, 0·25 kilo. ; and water, 3 kilos. ; to which, before evaporating to syrup, 150gr. of eosine are added. Ebony : Five kilos. of extract of logwood boiled with 11 kilos. of water, and, when near the syrupy state, 300gr. of iron nitrate added ; evaporated to syrup under constant stirring. All the above stains are brought into a dry condition by running the respective syrups into trays of sheet iron, with low rims, in which the syrup hardens, and is afterwards broken up and ground.

**Every Workman** connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade ; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

**Holloway's Pills.**—These Pills cleanse the vital fluid from all contaminations, and by that means strengthen and invigorate the whole system, healthily stimulate the sluggish organs, repress over-excited action, and establish order of circulation and secretion throughout every part of the body. The balsamic nature of Holloway's Pills exercises marvellous power in giving tone to debilitated and nervous constitutions.

## TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve months, Post Free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII., XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., and XL., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words .. .. .. .. .. .. .. | 2 | 6 |
| Every additional eight words .. .. .. .. .. | 0 | 6 |

Front Page Advertisements Five Shillings for the first 40 words, afterwards 9d. per line. Paragraph advertisement inserted for per line. No front page or paragraph advertisements One Shilling less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. | d. |
|---|---|---|
| Sixteen words .. .. .. .. .. .. .. | 0 | 6 |
| For every succeeding Eight words .. .. .. .. | 0 | 6 |

⁂ It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday, to insure insertion in the following Friday's number.

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words, and 3d. for every succeeding 8 words.*

**"English Mechanic,"** Vols. XVII. to XXXIX., £3.

**"Knowledge,"** 1 to 54, 2 and 3 wanting. Offers —Robson, Albion-place, Newcastle-upon-Tyne.

**Palmistry.**—Character, &c., read at a glance. Chart, with full particulars, 7d.—H. Dyke, 21, North-street, Taunton.

**Francois' Specialities.** — Fourth year. Giving universal satisfaction. Model Engines, Spectacles, Telescopes, &c. Catalogue, 2 stamps.

**A. Francois,** Specialist, Ryland-road, Birmingham, respectfully solicits inquiries from abroad.

**Repousse Work.**—Tools, Materials, and Instructions may be obtained from A. Francois, Birmingham, Particulars on application.

**Model Engine Castings.**—Five pounds will be given to the maker of Best Model Launch Engine, double cylinder, 1in. bore, 1¼in. stroke. Castings, 5s.; coloured drawings, 1s. Send stamp for full particulars.

Single-cylinder **Launch Engine,** 1in. bore, 1¼in. stroke; post free, 3s. Excellent design. Coloured drawing, 9d.

**Horizontal Engine,** 1¼in. bore, 2in. stroke, 5s. Coloured drawing, 9d. Double cylinder, 10s.; coloured drawing, 1s.

**Horizontal Engine,** ½in. bore, 1in. stroke, 1s. 9d. Drawing, 6d. ¾in. bore, 1¼in. stroke, 2s. 8d. Drawing, 6d.

**Model Engines Repaired.** Turning, Boring, Planing, Screw-Cutting, &c. Separate parts of every description, finished and rough.

Send for **Catalogue, 2d.** Six Lithographed Designs, 3d.—Hughes' Mersey Dockyard, 17, Smith-street, Kirkdale, Liverpool.

**Dorrington's World-renowned Castings,** comprising Stationary, Launch Engines, Gas Engines, Pumps, Cylinders, &c., and Models of every description. List, 1 stamp.— A. Dorrington, West Gorton, Manchester.

**See Last Week's Advertisements.** Enclose stamp for Price List of Castings and Working Drawings.—A. Dorrington, West Gorton, Manchester.

**Microscope Objectives,** 1in., ¼in., English lenses, cheap.—W. Butler, 44, Elsden-road, Bruce Grove, Tottenham, N.

Two H.-P. **Launch Boiler,** new, cheap.—RESIDE, Brighouse, Yorks.

The **Unique Hand and Power Drill.** Amateur Drills, 25s., or Castings for Drills, Lathes, Engines, &c.

**Lathe Carriers,** Chucks, Turning Tools. Sample Carrier or Tools, free, 1s.—Reside, Brighouse.

5½in. back-geared **Lathe,** 5ft. bed, turned flywheel, roller, treadle motion.—Reside, Brighouse,

**Lakmoid,** Methyl. Orange, and Phenol Phthalein, more sensitive than litmus; samples, six stamps.—A. Jackson, Ashley-road, Bowdon.

Steel **Name Stamps,** 3d. per letter. Figures (set), 2s. 4d. Letters, 6s. 4d., per post.—E. F. Baldwin, Robinswood-hill, Gloucester.

**Fountain Pin,** carriage free, 7 stamps. Wonderful Penny for passing into a bottle, 1s.—A. Jones, 98, Packington-street, London.

For sale, **Vertical Boiler,** with tubes, good, 4ft. high, 1ft 6in. diameter, fittings complete, £5.—Apply, H. Marrion, Windmill Inn, St. James's-road, Croydon.

**Photographs Printed** cheaply from amateurs' negatives; Carte size, 2s. 10d. per dozen.—Address, Photo, 182, Trongate, Glasgow.

**J. H. Stafford,** Practical Repairer of all kinds of Sewing Machinery.— 17, Bradshaw-street, Shude-hill, Manchester.

**Incandescent Fairy Lamps,** post free, 7d.—W. Hargood, Hazlebrook, Buccleuch-road, West Dulwich, London, S.E.

**Cholera Preventive and Cure.**—Have it in your houses (Chlorodyne). Recipe, 7d.—Stanley, 119, Manchester-road, Poplar.

Humber **Tricycle,** nearly new, perfect condition, adjustable saddle and handles, cash £13 1 s.—180, London-road, Sheffield.

**Water Motors,** for sewing machines, organettes window advertisements, 32s., 42s. List one stamp.—Wheeler.

**Fan Castings.**—Improved Registered Designs; sets 4in., 3s.; 6in., 4s.; 8in., 5s. Drawings, 4d.—Wheeler, Engineer

**Water Motors.**—Complete one horse-power, £9. Half, £6; Quarter, £4; Eighth, £3.—Thomas Wheeler, Preston.

**Fretwork.**—Every requisite for this work kept in stock. Send for list.—Walter Willey, Kirkgate, Leeds.

**Oscillating Engine,** 2in. bore, 4in. stroke, cylinder, bed-plate, &c., brass, wood base, painted imitation brickwork, complete all but testing, cash 25s.—Patrick, Chelmsford.

Screw-cutting **Lathe,** 4½in. centre, 4ft. bed, with gap nearly new, £15.—42, King-street, Woolwich.

**Cassegrain,** 4½in. metal mirror, and silver-on-glass convex, 10s. 6d.—Dolby, 6, Albion Hill, Leicester.

**Water Waste Preventers,** all brass fittings, especially made for strength, 24s.—Knight, Reading-road, Basingstoke.

**Engine,** three-horse oscillating, no flywheel, very cheap.—Manning, Electrotyper, 28, Old-street, St. Luke's.

Volumes I. and III. to VIII. **"English Mechanic,"** good condition. What offers?—C. Curtis, Market-street, Scarborough.

Singer "Challenge" **Tricycle** for sale, ball bearings and lamps, complete, cost £24; will take £9.—L. Garratt, 5, Factory-terrace, Halstead, Essex.

Half-Horse **Engine,** vertical, copper boiler, working order, £5 15s.—E. V., 95, Wirtemburg-street, Clapham.

Vertical **Engine** for sale, no worse than new, 1½ horse-power, price £4 15s.—Apply, J. H. Evans, 30, Trealaw-road, Trealaw, near Pontypridd, Glam.

**Microscopic Glass Slides,** 6s. Cells, 14s. per gross.—H. Howard, 7, Chichester-terrace, Shepherd's Bush, W.

**Thin Covers.**—Squares, 3s.; Circles, 4s. 6d. per ounce. Troughs, Stage Plates, and Microscopic Materials.—As above.

**Gas Engine,** ½ h.p., in first-class working order. Can be seen at work. Price £22.—T. Evans, 61, Denbigh-street, S.W.

Small **Dynamo** for sale, little used. Also a Magneto —A. C. Hervey, Portchester, Fareham, Hants.

## Wanted.

Agents Wanted.—Morgan's celebrated Improved Scale Preventing Compound. Nothing better or cheaper.—W. H. Morgan, Engineer, Gloucester.

Old Microscopes.—Send rough sketch, with dimensions state, and price, to J. Mayall, Junior, 224, Regent-street, London, W.

An old correspondent wishes to obtain either Porcelain, Glass, or Stoneware Rolls, 6in. dia., 8in. or 10in. long, truly hung on their shafts, for grinding purposes.—C. D., care of Bookseller, 155, High-street, Battersea, S.W.

Wanted, Steam Launch, about 16ft., or Steam Canoe; must be good, and a bargain, cash.—Fire Brigade, Pontypool.

Wanted, Root's Blower, small size. State price, size, and condition.—H. Allison, Harris-street, Bradford, Yorks.

## Addresses.

All desirous of making a cheap Engine Oil (935°), splendid Lubricator, communicate with J. M., 6, Hamlet-street, Bootle, Liverpool.

Will makers of "Invicta's" Gas Generator communicate with W. J. Barry, Broadisland, Ballycarry, Co. Antrim, Ireland?

## Situations.

Scientific Instrument Maker seeks Situation as Assistant to scientific gentleman, in laboratory, or in any place of trust; at present engaged in optical trade.—Address, 99, Northcote-road, Wandsworth Common, S.W.

Mechanic seeks Situation; accustomed to eyelet-making machinery.—J. W., 333, Halifax-road, Rochdale.

---

**CITY AND GUILDS OF LONDON INSTITUTE.—FINSBURY TECHNICAL COLLEGE.**

EVENING DEPARTMENT for Apprentices, Journeymen, Foremen, and others. Instruction in Mechanical and Electrical Engineering, Technical Chemistry, Applied Art, Cabinet-making, Metal Plate-work, Builders' and Plumbers' Work, Carpentry and Joinery, Bricklaying, &c.

Fees from 6s. to 30s. for the Session, inclusive of laboratories and workshops.

The SESSION COMMENCES on MONDAY, OCTOBER 5th.

Apprentices are admitted at half the ordinary fees.

For further particulars apply at the College, Leonard-street, City-road, E.C., or at Gresham College, E.C.

PHILIP MAGNUS, Director and Secretary

---

**CITY AND GUILDS OF LONDON INSTITUTE.**

TECHNOLOGICAL EXAMINATIONS

The NEXT EXAMINATION will be held on MAY 26, 1886. Teachers desiring to form classes should apply at once to the Director, at the Offices of the Institute, Gresham College, E.C., or at Exhibition-road, S.W., from whom particulars of all branches of the Institute's work may be obtained.

PHILIP MAGNUS, Director and Secretary.

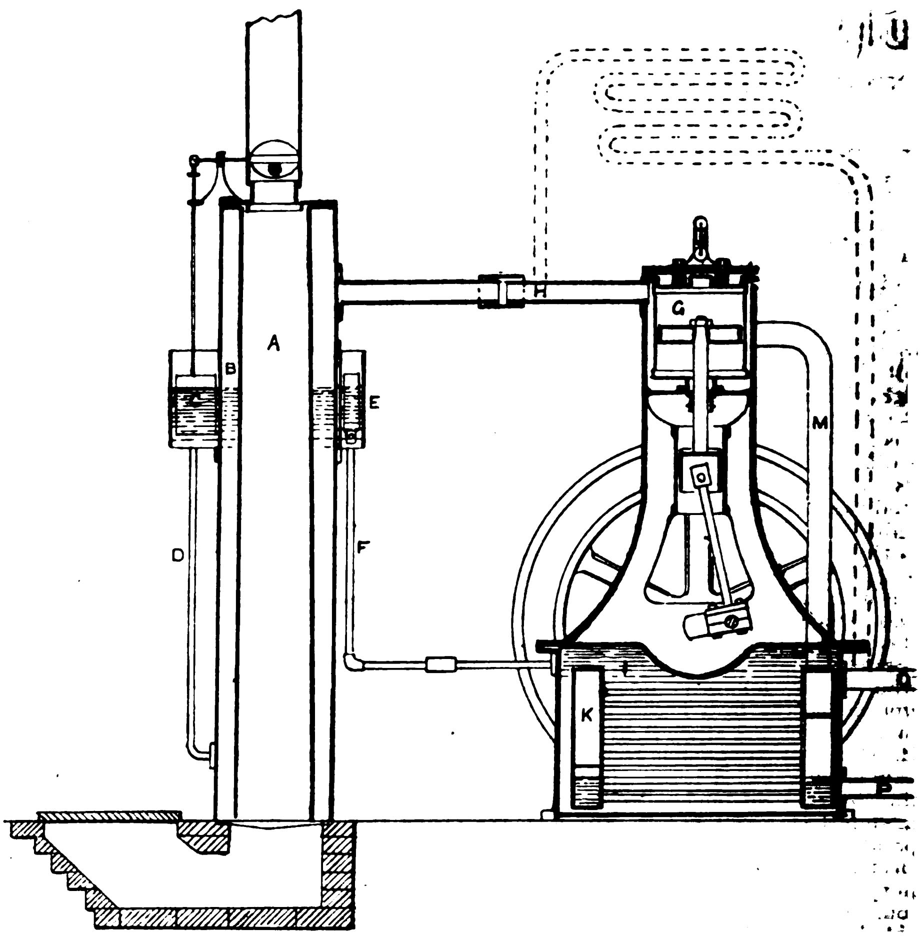
AND WORLD OF SCIENCE AND ART.
*FRIDAY, AUGUST* 21, 1885.

# PRIVATE INSTALLATIONS OF ELECTRIC LIGHT.

THE simplest arrangements for using the electric light in houses are those in which batteries and incandescent lamps are connected up in separate circuits, each with its own switch; but for reasons which are by this time tolerably well known only those with long purses can afford this method of lighting, and they will not be bothered with the trouble and mess of batteries. The secondary battery, charged by a dynamo, is a different arrangement altogether, and has its advantages; but those who desire to study economy while enjoying the electric light, prefer to take the current as cheaply as they can get it from the dynamo, and pass it direct through the lamps. The late Sir W. Siemens did good service a few years ago by putting up an installation of the electric light at his country seat, though possibly the great majority of those who have followed in his footsteps were influenced in a higher degree by the success which was attained by Mr. Octavius E. Coope at Berechurch Hall. There are now many so-called private installations of the electric light, and not a few amateurs having steam or other power at their disposal have utilised it for the production of electric light in their homes, for special purposes if not for general use. Although some use small arc lamps, which are invaluable in certain circumstances, it is generally conceded that the incandescent lamp is the only one that is really adapted for what may be termed "domestic" illumination. At the meeting of the Institution of Mechanical Engineers, held the other week at Lincoln, Mr. Ralph H. C. Nevile read a paper in which he gave an interesting account of the manner in which he lit up his residence, Wellingore Hall, Grantham. It seems that he had a 6 h.-p. portable engine about ten years old that had been used for pumping and for driving a saw, which he determined to utilise for his purpose, although it had one of the old-fashioned governors with heavy balls, and consequently promised to give trouble. The wiring of the house was put into the hands of a firm of electrical engineers, and a Siemens compound shunt wound dynamo was obtained, and placed with the engine in a shed about 180 yards from the point where the cables enter the house. The total number of lamps in fifty rooms and offices is 125, but the maximum number required at one time, except for purposes of experiment, has never exceeded fifty. All the main wires or leads are of sufficient size to allow of the number of lamps being increased to 200. The dynamo is driven direct from the flywheel of the engine by a 4in. linked leather belt, which from the absence of laces or joins is well adapted to the work. From the dynamo the current is led to a set of switches, whence it can be distributed into five circuits—the first exciting the F.M.'s of the dynamo; the second taking current to the engine-shed and carpenter's shop adjoining; the third goes to a schoolhouse near; the fourth goes by an overhead cable to the hall, a branch being taken off to light the stables; and the fifth supplies current to a number of lamps (100) which are fixed on a board for purposes of experiment. The last-mentioned circuit is also intended for use in charging secondary batteries which Mr. Nevile hopes to try before long. The switches are of the two-way type, so that the current can be sent to the leads direct, or can be passed through an Ayrton and Perry spring ammeter, by which the amount of current in use on any given circuit can be ascertained. The current for the house circuit is taken by an insulated cable of fourteen No. 16 wires from the dynamo to the roof of the shed, where it joins a bare cable of the same size, which is suspended on poles and led to the main cable in the house, which has nineteen No. 14 wires. This large cable has been fitted in order that a greater number of lamps may be employed if deemed desirable at some future time: it passes into the middle of the house, throwing off branches on its way, and then connects to a smaller cable, which is in turn connected to a still smaller one, until the end of the house is reached. Fusible cut-outs are provided at the junctions of all the branches with the mains, and most of the switches used have fusible plugs, and are of the quick-breaking type, which cannot be left in such a position as to form an arc. The lamps themselves are mostly 20 candle-power Edison and Swan, of 100 volts; but in some places two 50 volt 10-candle lamps in series are used instead, as, for instance, in passages, which are thus better illuminated by the greater diffusion of the light. Chandeliers with incandescent lamps are used in parts—for instance, in the chapel; but, as a rule, the lamps are attached to the wire-ends, or carried on the old gas brackets. In his private workshop Mr. Nevile has a few lamps attached to flexible wires, which he finds very convenient when working at the lathe. So far the general arrangements, which are just what would be adopted by any firm of electrical engineers engaged to make the installation; but now we come to the main difficulty of all electric light installations on the comparatively small scale, and, for that matter, of all in which the prime mover is not more than sufficient, and is not controlled by the devices which have been introduced for producing perfectly steady action. As might be expected, Mr. Nevile found that his engine, while quite up to the work required of it, had a governor which was utterly unsuitable, for the inertia of the heavy balls is so considerable that the position remains the same during considerable variations of speed; so much so, in fact, that although an adjustable resistance had been introduced into the circuit exciting the field magnets, it was found impossible to keep the electro-motive force to the point required. Mr. Nevile, early in his experience, seems to have "touched the point," for he not only discovered that perfectly steady motion was requisite, but also that each dynamo ought to be specially wound for the potential desired and for the external resistance between the lamps and the dynamo; in other words, that the machinery employed should be accommodated to the conditions. All sorts of schemes have been devised to simplify installations of electric light; but as those who have been engaged in the work know, it is not an easy matter to make the actions of the drivers altogether harmonious with the conditions required by the driven. Thus, the main leads to Mr. Nevile's house, having a resistance of about ·2 ohm, there is a loss of about 12 volts of E.M.F. when 60 ampères are passing along them between the terminals of the dynamo and the house; whereas when only one or two ampères is the quantity of current, the loss is practically *nil*. If, then, the E.M.F. is constant at the dynamo, it falls at the house as the lights are turned on. This difficulty is supposed to be met by the use of an isochronous governor and a compound wound dynamo; but, as pointed out above, each dynamo, to give the best results, ought to be wound specially for the work it has to do. Consequently reserve machines are not competent to undertake the work of an installation unless the number of lamps are reduced or increased to suit the machines. But the question is, how to illuminate a country house by electricity with the same convenience that gas now affords, and it is obvious that the number of lamps in use cannot always be adapted to the conditions required by the machines, and certainly it is impossible to alter the latter to suit the conditions of the illumination. If secondary batteries are interposed, there is the disadvantage that in the case of compound wound dynamos the current may flow back and reverse the polarity of the machine if the engine is slowed down before the connection is broken. The plain shunt-wound dynamo is free from that objection; but even in that case, when more lamps are added to the circuit the electro-motive force falls just when it should rise. Mr. Nevile having seen the Richardson electric regulator at work, determined to try it on his engine, although the latter was of a type which does not readily lend itself to the introduction of the necessary valve. The Richardson regulator can be seen at the Inventions applied to a semi-fixed compound engine by Robey and Co., Stand 433, and is designed to maintain either a constant current or a constant electro-motive force, irrespective of variations in boiler pressure or work done. It is obvious that in country districts, and many other places, it would cost rather too much to devote as much attention to the engine as is done by the driver of an express locomotive; and it is, therefore, practically impossible to keep the boiler pressure steady, while even if that could be achieved the variations in the work would still necessitate some sort of "regulator." The Richardson regulator consists of a double solenoid magnet, placed vertically, and wound with insulated copper wire; a double core works within the solenoid, and the crosspiece connecting the cores is attached to a lever, the short arm of which presses upon the spindle of a double-beat Cornish valve controlling the admission of steam to the chest. The speed of the engine is by this means regulated by the conditions of the circuit. For incandescent lamps in parallel the wire on the bobbins is placed in shunt circuit between main leads, the size being adjusted to the electro-motive force which it is desired to maintain between the mains, so that the cores are kept suspended within the solenoids. As the resistance of the solenoids is fixed, any increase of electro-motive force causes an increased current to flow through them, and the cores are immediately attracted by an increased force, and thus, acting through the lever, close, or partially close, the valve until the electro-motive force has been reduced to its normal amount. The arrangement is superior to an automatic expansion gear, because, with the latter, when but a few lights are on, the steam is cut off so early in the stroke, that unless the flywheel is exceptionally heavy, a fluctuation in the light can be seen at every revolution, somewhat similar to the unpleasant bobbing in electric lamps worked by a gas-engine. The Richardson regulater was set to work at Mr. Nevile's last January, and the improvement produced by it was remarkable, the lamps remaining fairly steady without sudden alterations of brightness and dulness in their incandescence; but it was found that with any considerable variation of boiler pressure or of load the electro-motive force in the mains varied more than was considered conducive to long life in the lamps. By augmenting or diminishing the weight suspended from the core-bars, it was found the electro-motive force could be brought back to its normal amount, and Mr. Nevile adopted the plan of fixing an upright cylinder in direct communication with the boiler, and making its piston rod press upwards on the core-bars. When the load varied considerably—say, from one lamp to a a hundred—even this plan was not successful, or rather not sufficiently so for Mr. Nevile, who modified the arrangement by causing the piston-rod to act upon a lever, and introduced a second cylinder supplied with steam from the chest, the piston-rod of the latter acting upon the same lever, but on the other side of the fulcrum. The resultant effect of the differential power of the two cylinders can be easily adjusted by the means provided, and the number of lamps can now be varied from one to one hundred, and the boiler-pressure from 30lb. to 60lb. with very slight variation of electro-motive force in the mains. Mr. Nevile's experience with the Richardson electric regulator satisfactorily establishes the utility of that invention, which has, we believe, been severely tested at the works of Robey and Co., Lincoln. In the discussion which followed the reading of the paper Mr. Crompton expressed an opinion that electric force was not practically applicable, for by improper packing throttle-valve spindles might offer from 30 to 40lb. resistance to movement; but, be that as it may, others besides Mr. Richardson have been moving in this direction, and it will be a triumph for both mechanician and electrician to make the electric current regulate itself, whether the actual movements of the steam-valve are produced by steam or hydraulic power, or are produced as well as controlled by the electric current. For the successful installation of electric light for domestic purposes in isolated examples, it will be seen that many points have to be studied; but with such experimenters as Mr. Nevile we are likely to reach much nearer perfection than we are by the help of limited liability companies.

## THE DAVEY "SAFE" DOMESTIC STEAM MOTOR.

THE "low pressure" steam engine recently patented by Mr. Henry Davey, of Leeds, which has attracted much attention in consequence of its complete immunity from risk of explosion, is illustrated and described in the following. The motor is shown in action in the West Annexe at the Inventions, stand 1,195; but as manufactured is more compact than appears in the illustration, which is expanded to show the parts clearly. The invention includes low pressure steam boiler, engine, and condenser, specially suitable for electric lighting in private houses and for working domestic machinery, where it is important to provide against all risk of explosion. The boiler is self-feeding in respect of fuel and water, and is in the form of an upright vessel having a central space for the fuel and an annular space for the water surrounding the fuel space. Communicating with the water space of the boiler there are two float chambers, one having a float for regulating the supply of feed water, and the other a float for regulating a damper in the chimney. The latter float chamber communicates by a pipe with the lower part of the boiler and is open to the atmosphere. While the pressure in the boiler is equal to that of the atmosphere the float is kept up, and the damper which is connected to the float is closed or nearly so. When the pressure in the boiler falls below that of the atmosphere, the water in the float chamber being pressed into the boiler descends, and the float also descending opens the damper. The float in the chamber for regulating the feed water supply in descending opens a valve admitting water to the boiler. The fuel chamber has, at its bottom, fire bars, on which the fire is lighted, the chamber being then filled up with fuel which descends as that below burns away, fresh fuel being added from time to time if desired. By this arrangement, the necessity for frequent stoking is avoided, the fire burning for a considerable time without attention. Connected with the boiler a low pressure engine is arranged to work with steam at or below the atmospheric pressure. It has an inverted steam cylinder by preference made of bronze or gun metal to avoid the necessity for lubrication. This cylinder is inclosed in a steam jacket mounted on a framing, the base of which constitutes a surface condenser consisting of a number of horizontal tubes surrounded by water. The water space is connected by a pipe to the feed water float chamber. There is also a pipe supplying cold water at the bottom, and a pipe leading off hot water from the top. These pipes communicate respectively with the lower and upper parts of a tank, so that when the engine is at work, the water circulates through the condenser and the tank until the water becomes too much heated for circulation. The tubes of the surface condenser connect two end chambers from which an air-pump draws the water of condensation and such air as may accompany it, discharging into the water space of the condenser or into the circulating tank. By this arrangement, the same water may be used over and over again for steam, and, as the cylinder of the engine requires no lubrication, no lubricant can get into the boiler to interfere with its action. The pump might, however, if desired, discharge into a drain. The drawing shows in longitudinal section, partly in elevation, a boiler and engine according to the invention. A is the fuel chamber and B the water chamber of the boiler, C is the float for regulating the damper, and D the pipe connecting the float chamber to the bottom of the boiler; E is the float chamber for the feed water, and F the pipe connecting it with the condenser chamber; G is the steam cylinder, and H the steam pipe connecting the cylinder jacket with the boiler; I is the condenser chamber, and K the condenser; M is the exhaust pipe of the engine leading to the tubes of the condenser K. An air-pump is attached to the side of the condenser; O and P are the circulating pipes communicating with the tank, which it is unnecessary to show.



## THE INTERNATIONAL INVENTIONS EXHIBITION.—XVI.

### Indiarubber, Guttapercha, &c.

INDIARUBBER and guttapercha are properly ranked amongst the most remarkable products of nature, though they owe much of their reputation for utility to the art of man. Rubber or caoutchouc is the inspissated juice of a variety of plants, which, as a rule, grow in countries where the mean temperature is as high as 80° Fahr., and the best qualities are obtained from the species of Hevea, the most important of which is the Hevea Brasiliensis, which flourishes in the dense forests on the banks of the Amazon. The milky juice of these trees is rapidly coagulated by exposure to the air, and when dried over a wood fire is known in commerce as bottle or ball rubber, according to the method adopted in preparing it for market. The best is known as Para rubber, and is obtained from species of Hevea; but the fact is that, although botanists and travellers have found several species of trees which yield caoutchouc, nothing is definitely known as to the range of rubber-bearing trees. Caoutchouc is obtained in Brazil from the *Manihot gladiovii*, from the *Castilloa elastica* in parts of Central America, and in the eastern hemisphere from the *Ficus elastica*, the *Urceola elastica*, and the *Landolphia Kirkii*, which latter probably extends throughout the whole of tropical Africa. Guttapercha is also a milky kind of juice yielded by trees of the natural order Sapotaceæ, and is of more recent introduction to the arts than caoutchouc, which it closely resembles in some respects. Caoutchouc and guttapercha have both been found of great value in the industries and arts, as well in their natural state as when manufactured; but so far as rubber is concerned, it is chiefly when the inventor. has played his part that its great usefulness is seen. The exhibit of the Indiarubber, Guttapercha, and Telegraph Works Co., which forms a prominent object in the East Quadrant of the Inventions Exhibition, shows in an excellent manner what can be done with caoutchouc and guttapercha, for besides samples of the raw materials from Borneo, Africa, and Peru, we have specimens of the numerous useful articles which can be manufactured from these natural products through the discoveries of Goodyear in the United States and Hancock in this country. The remarkable, not to say extraordinary results which follow the mixing of the rubber with sulphur, and the subjection of the compound to heat and pressure, rank amongst the most important discoveries of the century The manufactured material is so hard that it can be used in the shape of pumps and air-vessels for acid and other liquors; and by a simple alteration in the processes can be employed also for making driving belts, in which the maximum of flexibility and durability are required. A belt shown by the company has two plies of some cotton or flax fabric completely buried in caoutchouc, and although it is 320ft. long and 18in. wide, it weighs only five hundredweight. Belts of that kind are used more extensively in America than in this country, where the older fashioned leather belt still holds the first place. Among substitutes for rubber, the vulcanised fibre of Mosses and Mitchell, Chiswell-street, E.C., has come into somewhat extended use. It is made both hard and flexible, as a substitute in the one case for metal, vulcanite, ebonite, ivory, &c., and in the other for rubber, leather, gutta-percha, &c. A. H. Huth, of Ennismore-gardens, S.W., exhibits a number of articles in "imperishable rubber," the method of preparing which is, however, not described. Judging by the smell, camphor enters into the manufacture, and if we may accept the statements of the labels, the process is an improvement, for ¾in. hose, capable of withstanding 300lb. pressure, is priced at 6d. a foot, while valves tested to 22 tons are marked "about 3s. 6d. per lb." In this group (XXI.) we find an exhibit of linoleum, with paper foundation, for damp walls, and specimens of the manufactures of the British Xylonite Company, including xylonite and celluloid in sheets, rods, and tubes, and sundry applications of this very useful discovery, in the shape of facing for piano keys, knife handles, surgical instruments, &c.

### Leather, &c.

The group devoted to leather, &c. (XX.), though the number of exhibits is small, is attractive from the public point of view, for Woollams and Co., of High-street, Marylebone, exhibit their embossed, painted, and lacquered leather wall-hangings, screens, &c.; tergorine, an artificial leather for the same purposes, both of which are inodorous, washable, and non-poisonous—that is, they are free from arsenical colours. Jeffrey and Co., of Essex-road, also exhibit specimens of embossed leather, gilded and hand-painted, for hangings and mural decoration; their leather papers are an attractive feature of this part of the exhibition. Both firms sell the material plain, prepared for painting, so that "artists" can put their own work on their own walls. S. E. Norris and Co., of High-street, Shadwell, have a fine exhibit of leather, mostly in the shape of belts and bands, and have adopted the praiseworthy plan of labelling each exhibit with a ticket which refers to a book of photographs, woodcuts, &c., showing the processes undergone by the respective samples, and the machines employed in the work. Specimens of double leather belts are shown in considerable variety, and sewn on different plans with hemp, hide, flat copper wire, &c.; bucket leathers and rings for hydraulic rams are also shown. But the greatest novelty at this stand is Sapworth's patent wood-link belting, in which the belt is made up of a number of pieces of wood, faced with leather on the pulley side, and connected together by iron pins. It is constructed on the same plan as the leather link belts, but the links are larger. Belts can be made of any length, and up to 6ft. in width; but they are somewhat heavier than double leather belts, though the cost is only about half. A belt of this construction is easily joined up at any link by the insertion of one rivet or pin, but it is not quite clear how "increased frictional hold" is obtained. A compound material which is said to possess the qualities both of leather and indiarubber is exhibited by the Dermatine Syndicate, William-street, Camberwell, S.E. At a guess, it might be said to be a preparation of casein, and it certainly seems well adapted for the outer soles of boots, as shown at the stand. It is said to be perfectly waterproof, unaffected by climatic changes, to be acid, oil, and grease proof, and capable of withstanding high temperatures—some specimens of it more than 300° Fahr. E. Wilson, of Exeter, exhibits a patent striking and scouring machine for hides, which is said to do the work of six or eight skilled men, the drum being capable of being raised, lowered, or revolved during the processes. W. Warwick, of Bolton, Lancashire, exhibits a glossing machine, in which the rubber is of glass; and Carpenter Brothers, of Wellington-street, S.E., exhibit a cutting machine on the principle of the bookbinder's plough. Altogether, the group devoted to leather is scarcely worthy of this exhibition. The group devoted to Clothing is also small and insignificant, and some of the stands might have been with advantage included under the head of leather, &c.—for instance, the ingenious machines for making boots shown by the Northamptonshire and Leicestershire Boot and Shoe Machinery Co., Leicester, and by Salmon and Co., Kettering. In the group named Clothing we find a "permanent accordion pleating machine" entered in the catalogue; while Turner and Sons, of Redditch, show their wire-drawing apparatus for the production of pins and needles. Sewing machines also fall into this group, for Bradbury and Co., of Oldham, exhibit their rotary shuttle machine, an ingenious device, which carries far more cotton than the spools or the old bobbins, and is also fitted with a rotary pedal, which is much approved by those who have to work a sewing machine all day long. Thomas and Co., of Holborn Viaduct, exhibit several improvements and new devices in connection with sewing machines, including their patent machine for sewing corrugated metal round the lining of ventilated helmets, a two-needle machine for glove making, a button-hole machine, and their waxed-thread machine for harness and similarly heavy work which requires the use of a waxed-thread. For some reason or other we will not attempt to explain, a patent oscillating motion devised by Mr. Warwick, of Hilton-street, Manchester, is exhibited in this group. It consists of a disc grooved in its periphery, and set at an angle on the axle or shaft; a roller running in the groove imparts an oscillatory motion to anything to which it may be attached.

### Aeronautics.

The group devoted to aëronautics, which is located in the East Avenue, is a practical failure, for it contains only a few models which have any even the slightest pretensions for navigating the atmosphere, and is so small in itself that the authorities have placed the chimney-climbing device (a mechanical arrangement for raising a cage by clasping the shaft) of Mr. P. L. Gray, Ratho, N.B., in the group. Lieut.-Col. Hime, of Weymouth, shows a working model of his wave-winged propeller, which is similar in principle to that exhibited in the Naval Architecture department, and is intended to show the propelling effect of wave-motion in wings. Mr. Thomas Moy, 8, Quality-court, E.C., shows a photograph of his aërial machine, which was tried in 1879, and did actually raise itself from the ground. The total weight was 216lb.; the three horse-power engine and boiler weighed 80lb., the cylinders being 2⅛in. by 3in.; the area of the revolving planes was 40 sq. ft., and of the two fixed planes 114 sq. ft. Mr. S. H. Hollands, of New Brompton, exhibits a direct high-pressure twin steam fan "avitor," which makes 1,500 revolutions and weighs only 6½oz., its maximum power being 1,100 ft.-lb. It consists in the arrangement of propeller blades on a vertical spindle, and probably represents in principle his aëro-dynamometer, a machine designed to gauge relative wind-pressure, vertically and horizontally, on inclined aëro-planes, the model of which has been removed to Chatham for experiment by Major Templar. C. G. Spencer, of Ringcroft-street, N., exhibits "improvements in the construction of balloons and aëronautical apparatus," which consist in the use of asbestos cloth, which, being fireproof, allows of the use of the old hot-air arrangement continuously applied by means of a "furnace" carried in the car. Altogether, these smaller groups of the exhibition help only to swell the size of the catalogue, as by a better arrangement they could have been easily introduced into other groups.

## THE INTERNATIONAL INVENTIONS EXHIBITION AWARDS.

THE awards of medals and diplomas to the exhibitors at the "Inventions" were published in the *Gazette* last week. Altogether 235 gold medals, 438 silver medals, 515 bronze medals, and 24 diplomas of honour have been awarded. It is needless to say that there is the usual amount of dissatisfaction; but the following selected list will be of interest to our readers:—

#### GOLD MEDALS.

**Beck, R., and J., microscopic and other optical apparatus.**
**Bell, John and Co., treatment of asbestos.**
**Benson, J. W., improvements in machine-made watches.**
Bessemer, Sir H., Bessemer iron and steel.
**British Gas Engine and Engineering Company, Limited, gas engines.**
Cardew, Capt., voltmeter.
**Common, A. A., celestial photographs.**
Coventry Machinist Company, cycles.
Crompton, R. E., and Co., improvement in electric lighting appliances.
Crookes, William, radiometers, &c.
Crossley Brothers, gas engines.
Evans, J. H., ornamental turning lathes, counting apparatus, excellence and accuracy of workmanship and cheapness.
Fletcher, Thomas, gas fires and furnaces.
Holtzapffel and Co., excellence of exhibit, good workmanship and accuracy, as evidenced by work done in lathes, &c., for turning, carving, &c., in wood and ivory.
Jenkin, late Prof. Fleeming, telpherage.
Joy, D., valve gear.
Maddox, Dr., replacing collodion by gelatine in the emulsion process of photography.
Phosphor Bronze Company, phosphor bronze alloys.
Planté, G. (France) secondary battery and scientific research.
Shaw, Professor W. S. Hele, sphere and roller mechanism for transmission of power.
Shaw, Professor, W. S. Hele, improved integrators.
Stanley, W. F., improvements in philosophical instruments.
Surrey Machinist Company, cycles.
Swan, J. W., incandescent lamps.
Swan, J. W., part taken by him in the invention of carbon printing.
Vacuum Brake Company, vacuum automatic continuous brake, with universal coupling.
Varley, S. A., designing the first self-exciting dynamo machine.
Webb, Francis William, exhibit of railway plant.
Westinghouse Brake Company, Limited, automatic air brake and passenger communication for railway trains.
Wilde, Henry, discovery of the indefinite increase of the magnetic and electric forces from quantities indefinitely small.

The following gold medals have been awarded by the Society of Arts on the recommendation of the juries:—

Sir Henry Bessemer, F.R.S., for the invention of Bessemer steel.
Percy Gilchrist, for the Thomas-Gilchrist basic process of steel-making.
Hathorn, Davey, and Co., for their domestic motor.
Samson Fox, for the invention of corrugated iron flues for steam boilers.
Crossley Brothers, for the "Otto" gas engine.
Ralph Tweddell, for his system of applying hydraulic power to the working of machine tools, and for the riveting and other machines which he has invented in connection with that system.
Badische Anilin und Soda Fabrik, for their improvements in the manufacture of colouring matters, and intermediate products from coal tar.
William Crookes, F.R.S., for his improvements in apparatus for the production of high vacua, and for his invention of the radiometer.

#### SILVER MEDALS.

Bailey, W. H., and Co., hydraulic hauling engine.
Bower, George, process for rendering iron rustless.
Bower, George, regenerative gas burner.
Brailsford, T. R., tide gauge.
Brin Frères, improvements in the production of oxygen and nitrogen gases.
Cunyngham, E. H., calculating machine.
Dixon, T., improvements in slide rules.
Ellis and Co., "Facile" bicycle.
Gerard and Co., Limited, lamps and dynamos.
Gillott, Joseph and Sons, specimens exhibiting processes in the manufacture of steel pens.
Glover, W. T., and Co., cables.
Gülcher Electric Light and Power Company, Limited, electric lighting apparatus.
Harrison, Cox-Walker and Co., electrical exhibit.
Jenkin, late Prof., system of gearing.
Jordan, J. B., sunshine recorder.
Kendall, J. A., gas battery.
Marion and Co., photographic apparatus.
Salomons, Sir David, electrical appliances and philosophical instruments.
Selig, Sonnenthal, and Co., turret head lathe.
Steward, J. H., optical apparatus.
Traill, W. A., electric tramway.
Trouvé, G., electrical appliances.
Voss, R., induction machine.
Ward, P., illuminating apparatus for surgical purposes.
Warnerke, L., progress in connection with film negative for photography.
Wenham Patent Gas Lamp Company, Limited, regenerative gas burner.
Wilson, W. J., harmonograph.
Wimshurst, James, induction machine.
Zuccato and Wolff, trypograph or multiple writer.

#### BRONZE MEDALS.

Albo-Carbon Light Company, albo-carbon light apparatus.
Allin, S. S., signal wire compensator.
Baker, C., student's microscopic apparatus.
Dale, H. and E. J., electrical exhibit.
Frost, A. J., transit instruments.
Gant, R. B., electrical exhibit.
Harling, W. H., improvements in mathematical instruments.
Irish, W. H., electrical exhibit.
Lee, R. A., electrical exhibit.
Mosses and Mitchell, vulcanised fibre.
Richardson, Dr. B. W., apparatus for extinction of life.
Rogers, Francis M., electrical exhibit.
Ross, Lieut.-Col. W. A., improvements in blowpipe analysis.
Sands and Hunter, adaptation of various improvements to photographic apparatus.
Spiller, A., gelatino-chloride of silver transparencies, developed with hydroxylamine.
Story, J. H., jaw-chuck for lathes.
Stott, J. and Co., gas governor for service pipes.
Thornthwaite, Horne, and Wood, improved limelight apparatus and photographic apparatus.
Thorpe, H., electrical exhibit.

# ENGINE-MAKING AT HOME—IX.

## Slide Blocks and Connecting Rod.

TAKE now the four guide bars and file their faces true. The greater the accuracy attained here the better, and it will be comparatively easy to get these true, since we can use them as surface plates for mutual trial. First, file all four as carefully as possible with the aid of a straightedge, then try them each one in succession upon each of the others, until all are alike interchangeable and in contact everywhere. This can only be ensured by scraping; but, as their surfaces are small, it will be a moderately easy task. The faces of the bosses (Fig. 109, *a*, *a*, *a*, *a*) will be filed at the same time level with the bearing surfaces, while the bosses upon the back will be filed parallel with the first, to a thickness of $\frac{9}{16}$in., the uniformity of the thickness being gauged with calipers from faces *a*, *a*. The sides must be filed straight and parallel to $1\frac{5}{8}$in., and equidistant from the sides of the $1\frac{1}{4}$in. bosses at the ends. A $\frac{3}{8}$in. hole will be marked and drilled in the centre of each boss, the centres measuring $10\frac{1}{4}$in. between, lengthways, the holes to take $\frac{3}{8}$in. tight-fitting turned studs. We may note that all bolts and studs in engine work should be tight fitting, since the continual vibration would cause displacement of the parts in cored holes and slack-fitting bolts.

It is now necessary to set the bottom bars parallel, both with the bore of the cylinder and at their exact distance below the central line of the piston rod—viz., $\frac{7}{16}$in.; that is, of course, equal to half the thickness of the slipper. There are two ways of doing this. One is to strain a chalk line through the centre of the cylinder, extending from a cross strip of wood at the back end, thence to the centre of the crank shaft bearing, and to measure from this line downwards to the faces of the slide bars, employing straightedge and level for the purpose, and sideways to their edges (Fig. 110). The other way, and one which is easily adopted with so small an engine, is to use the accurately turned piston and piston rod, fitting closely in the corresponding bored parts, together with the slipper blocks, as a means of testing the linear setting of the guide bars.

We shall already have levelled the tops of the bosses which sustain the slide bars by means of the spirit level, Article VI., page 294, so that presumably they are all in the same plane relatively to one another; and the bosses upon the guide bars, being filed parallel to the calipers, the slippers ought, when the bars are laid in place, to bear equally and evenly all along, as the piston rod, having the piston attached to it in the cylinder, is drawn along through the gland and cover. But if the fit in the latter is good, some slight variation in the slide blocks and their bars will almost certainly be perceptible to sight or touch. This will be corrected in respect of the higher parts by reducing the bed bosses, or those upon the back of the slide bars. If unfortunately either of the bosses have been filed too low, a bit of packing must be introduced—a thin bit of zinc, or tin, or paper. The edges of the slippers will indicate the positions of the inner edges of the guide bars. When the positions of these are finally set, then, from their drilled holes, the positions of the stud holes in the bosses of the bed will be marked and drilled to $\frac{5}{16}$in., and tapped with $\frac{3}{8}$in. taps.

The four distance pieces (Fig. 109) will now be turned on both faces to $\frac{1}{4}$in. thickness, and drilled to $\frac{3}{8}$in. diameter upon the face plate. The one marked A will be rechucked at right angles to the drilled $\frac{3}{8}$in. hole, and to the centre of the slide-valve rod, $1\frac{1}{8}$in. away from the centre of the slide block, and a $\frac{9}{16}$in. hole drilled to take the bush for the valve rod. Then the studs (Fig. 111), $3\frac{1}{2}$in. long, being screwed into the tapped holes in the bosses on the bed, the slide bars and distance blocks will all be screwed down, lock nuts being used, and the slippers tried along. A little easing of the bosses may, notwithstanding all our care, be necessary in order to insure freedom of movement between the slide blocks and the bars throughout their length. A $\frac{1}{4}$in. hole will be drilled in the centre of each oil-cup, and the brass covers, *b*, *b*, filed to fit over them.

Fig. 112 shows the connecting rod with a gib and cottar joint at the crank end, and a plain bored hole at the end next the piston rod, and this involves a careful bit of fitting up, the details of which will not, however, cause any real difficulty after what we have said of the other parts. There are at least half-a-dozen ways in which the ends of the connecting rod might be fitted. If we wanted to be very exact in taking into consideration the future wear of the brasses we should adopt one of those arrangements by which, though the brasses would wear, the distance apart of the centres should remain constant. With our arrangement the rod will become slightly shorter in length each time the cottar is tightened up, because there is no compensatory joint at the piston-rod end. But we can afford to neglect this in the present instance, and to employ a plain bored hole only for the cross-head pin.

Fig. 112 shows the connecting rod fitted up, but the brasses, the strap, the gib and cottar, and the end of the rod are shown separately from each other in Fig. 113, dimensioned to their finished sizes. The brasses we have already as rough castings, and now require the forgings. A bit of 1in. square bar; hammered out at the ends where the section is required of an oblong shape, and roughly rounded along the shank, and about 13¼in. length, will do for the actual rod. But the strap, gib, and cottar will be more suitably forged out of steel as being stiffer, and taking finer surfaces.

The rough forging of the rod is first chalked, and a longitudinal centre line marked upon it, and equi-distant from this centre line the width of the cottared end = 1in. is marked and filed parallel. Upon each face so filed, one other centre line is marked and popped, and equidistantly from these last lines, and at right angles with the faces first obtained, the rod is filed to ¾in. in thickness. The centre of the cross-head journal is marked at the opposite end, and at a distance of 12in. from this centre the rod is marked off and filed square across. Lastly, through this square end a cottar way to the dimensions of Fig. 113 is drilled and filed, and a set screw made and tapped in.

The strap brought to the dimensions in the same figure has its cottar-way also drilled and filed to the dimensions there given. The gib and cottar need no comment. The brasses are filed between the shoulders of their flanges to fit within the strap, and also in their joints, but they are not bored at present. The brasses may be made a close fit in the joint, or else left a trifle open, and a strip of leather introduced so that they can be tightened up at a future time without taking them out for the purpose of refitting. When they are now fitted into place, the strap will be slipped over the end of the rod, the gib put in, then the cottar driven home, and the set screw tightened against it.

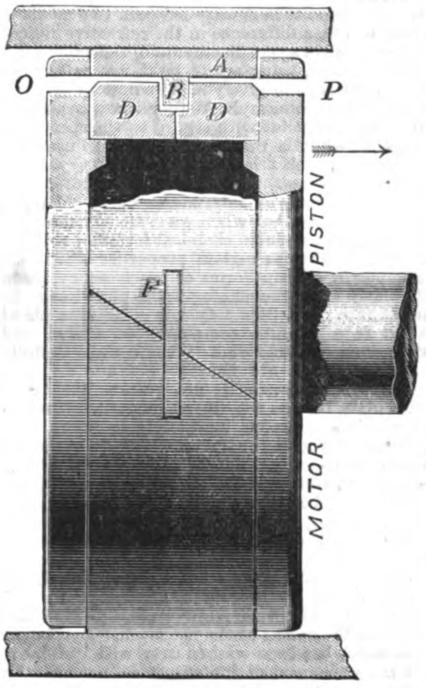
Before boring the brasses and the hole for the cross-head journal, we shall be cautious to check the exact centres, since if the brasses are out of truth, the centre at the opposite end of the rod alone can be readjusted. A circle ¾in. diameter will be struck upon the brasses, and one ¾in. diameter for the cross-head pin, their centres being 12¼in. apart. The brasses are better bored in place, but as this involves the possession of a lathe with a gap, they can be also bored when taken out and clipped in the dogs of the face-plate, care being taken to preserve their joints flush as though in their places before boring and facing. The opposite end of the rod will best be drilled in the lathe by means of a drill fixed in the slide-rest, while the eye of the rod is centred on the face-plate. Properly, this end also should be fitted with brasses and a cottar or a set block; but its wear is much less in amount than that of the crank bearing, and if it becomes slack in time, it is easily rebushed.

It only remains to remove the strap and its attachments, centre the rod in the lathe truly with the filed portions, turn it to the dimensions, and file and polish it with emery. The rounded end will be filed up neatly, oil-holes drilled, one for each bearing, and, if desired, small lubricators screwed into them.

## BRANDON'S PISTON PACKING.*

THE piston packing illustrated herewith is the outcome of the efforts of a practical and experienced mechanic to overcome difficulties that had come under his observation in machinery in his charge. Investigations and experiments on piston packing rings had satisfied him that when a piston moves forward, the inertia of the ring, and also the friction between the ring and cylinder, tend to make the ring bear tight against the rear flange of the piston, leaving a slight opening between the packing ring and the front flange of the piston. From this it will be understood that in pistons having packing rings cut for expansion, made in the usual way, when acting as pumping or compressing pistons, the working fluid will get on the inside of the rings, forcing them radially against the cylinder with a force equal to that of the pressure of the working fluid acting on the whole inside surface of the ring. He also found, by experiment, that a certain amount of the fluid under pressure creeps in between the rings and cylinder, tending to force the rings off their seat, this force being equal to about one-half of that of the fluid under pressure acting on the whole inside surface of the ring. As a result of his investigations and experiments, Mr. Brandon finally constructed the piston packing shown, the theory and operation of which may be understood from the following description:—The engraving represents a piston partly in section, in which A is the main packing ring cut for expansion, and a piece set in to break joint in the usual way, as shown at F. D, D may be regarded as part of the body of the piston, made in two parts, as shown, or in one part, or solid with the piston heads, as may seem advisable. B is a small ring fitted in the groove in the central part of the body of the piston, D, D. The ring B is cut for expansion, and a piece set in to break joint in the usual way. It is made to bear against the outer ring A the same as a packing ring bears against the cylinder. O and P represent two of several holes in the flanges, as shown. Now, assume the piston to be moving forward as from left to right in the engraving, and that it is used for a steam engine. The outer ring A will take the position in which it is shown. The steam pressure, being behind the piston, will pass in through the holes O, between the ring A and body D, forcing ring B against the forward side of groove in D, D. It may be seen that the pressure of the steam forcing the ring radially against the cylinder is limited to that of the inside surface of ring B and that part of ring A lying between ring B and the rear flange of piston, leaving that part of ring A lying between ring B and the front flange of piston relieved from internal pressure.

Assume the piston is used for a pump. Then as the pressure is in front of the piston it will pass through the holes P, or between the front flange and the ring A, forcing the small ring B against the rear side of the groove in D, D. Now it may be seen that when it is used for a forcing piston the pressure on the inside of the ring, forcing the ring to the cylinder, is limited to that of the inside surface of the ring B, and that part of the inside surface of the ring A lying between B and the front flange of the piston, leaving that part of ring A lying between ring B and the rear flange of the piston relieved of internal pressure through the holes O. The ring A is fitted in the usual way between the flanges of the piston, and B in the groove, the spaces on the side being left open so as to more easily understand the working from the engraving. The construction is not, of course, limited to that shown, which is intended to explain the principle involved. The aim is to provide a piston that shall be self-packing against pressure, but in which the pressure shall be so balanced as to permit neither the forcing the rings outwardly so hard as to rapidly wear out the rings and cylinder, nor the forcing them inwardly so as to permit the fluid to pass by them. Mr. Brandon has submitted the results of a large number of experiments he made in determining the proper proportions to secure the desired ends to Professor Robinson, who finds them to be in accordance with theory and with experiments which he has made. Packing made as described has been in use for, we believe, a year or more, with little or no wear of parts, and showing direct saving in power required to operate. The address of the inventor is James Brandon, 233, Tenth Avenue, New York.



IT is stated that in the German army salicylic suet is now used universally for foot-sores, sores from riding, &c., and is found much more satisfactory than the salicylic powder which was formerly used. The salicylic suet consists of 2 parts of pure salicylic acid, with 98 parts of the best mutton suet.—*Lancet.*

## ALKALOIDS AS DISEASE PRODUCERS.*

ALKALOIDS as agents in the causation of symptons of disease have grown into great prominence during the past few years. The interest that attaches to "cadaveric alkaloids" is both pharmacological and forensic. Perhaps no one has done more for the advancement of our knowledge of ptomaines than Professor Brieger, who has recently published "Weitere Untersuchungen über Ptomaine." As far back as 1866 Dupré and Bence Jones noted the presence of alkaloid-like substances in all the organs, tissues, and fluids of human and animal bodies. Owing to the flourescent appearance of the solutions of this alkaloid in weak sulphuric acid, the name of "quinoidin" was given to it. Nevertheless, Dupré and Jones did not succeed in obtaining ponderable quantities of the pure substance. In 1869 Sonnenschein and Zulzer obtained from a maceration of muscle an alkaloid having the property of dilating the pupils of rabbits and dogs. When injected into the jugular vein of rabbits, it increased the number of beats of the heart, and in two animals completely stopped the peristaltic action of the intestines. Rörsch and Fassbender found in 1871 in the liver, spleen, and kidneys, by the Otto-Stass method, a body having alkaloidal properties. It was a tasteless, uncrystallisable substance, and gave, with phospho-molybolic acid, a precipitate, which by warming and the addition of ammonia assumed an intensely blue colour. In the same year Schwanert extracted from the putrefying intestines, liver, and spleen of a child that died suddenly a peculiar-smelling fluid body that dissolved in ether. On the supposition that this was an alkaloid formed during putrefaction, Schwanert analysed the completely putrefied abdominal organs of a male corpse, and obtained a golden oil that smelt of propylamine, had a somewhat bitter taste, and gradually evaporated. The hydrochlorate of this body gave various reactions like those of alkaloids, but its toxicology was not investigated. L. Leibermann extracted from a putrefying stomach a coniine-like substance, which was taken up by ether from either alkaline or acid solutions. This substance had no poisonous properties. Traces of arsenic were found in the same stomach. In a trial for murder by poisoning, held at Brunswick in 1874, the expert in chemistry discovered, besides arsenic, a coniine-like base that Otto regarded as a ptomaine. It did not give the characteristics of nicotin, though resembling it in some respects. It was deadly poisonous, and killed a frog and a pigeon very rapidly. A similar kind of alkaloid was detected by Brouardel and Boutmy in the corpse of a woman who had died with symptoms of cholera, and who had partaken of a stuffed goose with ten other individuals. The base was also detected in the remains of the unwholesome goose. The substance was volatile, smelt strongly of mice's urine, and gave several reactions like those of coniine, though it differed in remaining colourless with muriatic acid, and could not be oxidised into butyric acid. It proved poisonous to frogs. In the cadaver resulting from prussic acid, and also in another due to charcoal fumes, the same authors discovered an alkaloid having a likeness to veratrin. Somewhat similar substances were also found in a body dead from arsenic, in one that had laid in water eighteen months, and in another that had succumbed from asphyxia. Wolkenhaar, again, extracted from the intestines of a woman who died from the excessive use of alcohol an alkaloid-like body having many features in common with nicotin; it was not toxic in its action. Morriggia and Battistina stated that dead bodies yielded much larger quantities of poison eighty days after burial in warm summer weather than when they were investigated in a shorter time after interment. These statements were made as the result of physiological experiments on frogs and rabbits. Extracts of the putrid tissues were made with pure or acidulated water, ether, ethyl-alcohol, or amyl-alcohol, and injected into the animals mentioned. Falling off in the number of heart-beats, loss of motility and sensation, and stoppage of the heart in systole were the phenomena noted.

The name of Selmi stands out most prominently in this field of work. It was he, if we mistake not, who first coined the word "ptomaine," which indicated the cadaveric origin of the alkaloids. It is now known that bodies undistinguishable from those discovered in the cadaver occur under many other circumstances. We may refer our readers to the article by Dr. Wolfenden, published in the *Lancet* of 1883, Vol. II., p. 852. The investigations of Guareschi and Mosso may also be mentioned (the *Lancet*, Vol. I., p. 827, 1883). Brieger lays much stress on the following propositions: That in the different stages of decomposition in the human body different basic products are formed; that many ptomaines disappear, their place being taken by others; and that certain bases, though present in spare quantities at the beginning of decomposition, gradually acquire a greater prominence as other basic substances disappear. A certain analogy exists between the above-mentioned changes and those met with in the putrefaction of albumen. Nencki has shown that for the formation of indol a certain temperature is necessary; whilst the production of phenol, according to Baumann and Brieger, is independent of temperature. Odermatt has proved for indol what Brieger has for phenol—that it disappears completely to make place for other aromatic products. In the course of putrefaction, cholin, which is probably derived from lecithin, is perhaps the first alkaloidal substance to make its appearance. On the third day what Brieger has called "neuridin" ($C_5H_{14}N_2$) can be found. Neuridin forms with picric acid a picrate which crystallises in feather-like masses of needles, which are almost insoluble in cold water and very difficult of solution in hot water. Neuridin is always found in company with cholin, but the latter gradually diminishes in quantity, whilst the former increases day by day. The fact that in slow putrefaction of human organs so strongly poisonous ptomaines can be shown to exist during the first few days deserves attention. About the time of the disappearance of cholin may be reckoned as the period when strong toxic products are developed. It is not known whether trimethylamin results from the decomposition of cholin or neuridin, but both these bodies contain its elements. Brieger refers to the appearance of a ptomaine on the seventh day which has hitherto been unknown. One of his observations showed that this new base was present even on the third day, though in very minute traces. With platinum salts, the new base formed dark red masses which were composed of needles mixed up with spangles and spicules. The purified crystals were of a somewhat brighter colour, and were found by Dr. Hirschwald to be about two millimètres in length, and to belong to the rhombic system of crystals. The crystals proved with polarised light to be doubly refracting. The base also forms a beautiful double salt with gold. This new diamin ($C_5H_{16}N_2$) is termed "cadaverin," and boils at a temperature of 115° to 120° C.; unpleasant its odour is, reminding one of coniine. A third diamin has also been differentiated, having the composition of a butylendiamin ($C_4H_{12}N_2$), but its reactions prove it to be a secondary diamin. The absurd name of "putrescin" is given to this substance, which may be detected on the fourth day of natural putrefaction, but is not present in large quantities until a week later. A fourth diamin, called "saprin," has also been isolated from the products of decomposition of human organs. Neuridin, cadaverin, putrescin, and saprin are physiologically almost harmless; cholin in large quantities produces physiological effects, like those of muscarin; whilst trimethylamin must also be given in large quantities in order to cause toxic effects. Brieger has, however, found two powerfully poisonous ptomaines in the cadaver. These poisons existed in large quantities on the fourteenth and twenty-first days of decomposition. One of these bodies is named "mydalein"; it exercises marked effects on the various functions of the body, increasing the nasal and lachrymal secretions, dilating the pupil, stopping the heart and breathing, and causing paralysis and death. Brieger has also investigated the nature of the products resulting from the action of bacilli in various media. He has separated highly poisonous bases from cultivations of the Koch-Eberth bacillus of typhoid fever. Intense salivation, diarrhœa, and paralysis were some of the toxic effects produced by these poisons.

## PHOTOGRAPHY AND THE SPECTROSCOPE.—III.[*]

By Capt. Abney.

IN my last lecture, I left off with the use of the slit in the spectroscope, and I showed you, I think, that under certain circumstances the slit which had the form of a ring was useful, having previously demonstrated that it was not necessary that the slit should be straight, but that it was most convenient that it should be so. I will next deal with the subject of the prism. We know that prisms are employed to separate the different coloured rays, as each colour is differently refracted as it passes through the prism, and it is this difference in the index of refraction between the red ray and the violet ray which gives the amount of dispersion in forming the visible spectrum. Of course, if we go beyond the violet, there are invisible rays, while again below the red there are also dark rays, which also have their indices of refraction, but I wish to show you the influence that the material of the prism itself has on the dispersion of the visible spectrum. I have here a prism of 60° built up of six or seven different triangles of glass. It is apparently homogeneous, but when we pass light through it we shall find that it is anything but homogeneous; in other words, the different portions are differently refractive. The different portions of the prism are all glass, as I have said, but of different densities, and the denser the glass, the more are rays refracted, and the greater dispersion between the red and violet there is. (A slice of light was passed through this built-up prism, and the different spectra thrown on the screen.) You will notice, by the spectra on the screen, that the length of the top spectrum between the red and violet is much smaller than that of the bottom spectrum. The glass which gives the dispersion to the latter is much denser glass than that which gives it to the former. Practically speaking, therefore, we may say the denser the glass the greater refraction, and the greater dispersion there is. For most purposes in spectroscopy, it is as well to use as dense a glass as possible in order to get the maximum amount of dispersion. I will now combine three prisms together, two of a light glass, and one of a denser, and we get a combination, in which, although the main beam will pass straight on to the screen, yet the presence of dispersion is also shown by the formation of a spectrum. This is an example of what is called a direct vision prism. The spectrum is given by the differences of the refractive indices for each ray in the two kinds of glass. For some purposes this kind of compound prism is very useful, and particularly for lecture experiments, but, as a rule, for photographic purposes I should not recommend it, on account of the internal reflections which take place between the different surfaces of the glass, though they are cemented together. You must recollect, wherever there is a difference in density between two media—in other words, a difference in the refractive indices—there is always a certain amount of reflection, and those reflections, being white light, are rather apt to fog the plate, and give you false notions of what you get in the photograph. We come now to a much more important point with regard to the spectrum, and that is, what is the best material to use. In those prisms which I have already shown you the material was glass. Now glass is, comparatively speaking, a mixture of materials, and has no definite chemical formula; but when we come to a material which has some definite chemical formula, we find that, as a rule, it has certain properties which are invaluable in certain forms of spectroscopy, more particularly when the photographic plate has to be brought into requisition. Quartz is an example of this; it is a definite compound of silicon and oxygen, and we find that it has certain definite advantages which are not to be found in glass prisms. The dispersion is not quite so great as it is with glass, but, on the other hand, it lets through rays which are cut off completely by glass, as I hope to show you on the screen. This quartz prism has very well-worked faces, and we will send a beam of light through it, and then proceed to investigate its behaviour. (Spectrum thrown on screen.) I may further say, in reference to this, that the condenser in that lamp is quartz, the lens is quartz, and the prism itself is quartz, so that we are dealing with nothing but quartz? Now, the question comes, Is there any advantage to photographers in using such a material as quartz? Let us first see the extent of the spectrum. By placing a card which has been washed over with quinine in the ultra-violet part of the spectrum, you are able to see these ultra-violet rays glowing with a pale blue light, and you will notice to what a great length these rays reach beyond the ordinary visible point of the spectrum. Now, by placing a piece of glass in front of the slit, you will see that the ultra-violet spectrum is very much shortened; in other words, the glass has absorbed these rays. I may repeat the experiment with a card which has been brushed over with paraffin oil, and the same result holds good. I have here a photograph of the electric arc taken in another manner, to which I shall have to direct your attention presently. The sight in this case has to pass through no glass whatever. The spectrum was taken by a diffraction apparatus; for the top part of the spectrum a glass was interposed in front of the slit, and we see the difference there is in the spectra, owing to the use of glass in one case, and not in the other. The glass apparently cuts off many useful rays; but I will now draw your attention to the solar spectrum taken in the same way, in which there has been a glass placed in front of the slit for one spectrum, and not in the other. Both spectra, practically, reach the same limits. We now can answer as to whether it would be advisable for photographers to use quartz lenses for ordinary photographic purposes or not. Recollect that every ray of light you saw fluoresce on the screen is useful for photographers when they are using a light such as we have in the electric light. You will see, then, from that, if the electric arc light was usually employed, all those rays which are cut off by the glass could not be utilised by them, and, therefore, there would be so much power wasted. Now photographers, as a rule, do not work with the electric light, but with sunlight; we have seen that in the solar spectrum taken under similar conditions the glass practically cuts off none of the ultra-violet rays; the atmosphere of the earth, or of the sun, or both, cuts off the extreme ultra-violet rays before the light reaches us. We therefore come to the conclusion that, so far as photographic work with sunlight is concerned, there would be no advantage in using a quartz lens over the ordinary photographic lens. Some years ago, Mr. Claudet made an agate lens, which he considered would give him greater advantages over the ordinary photographic lens, simply because he could utilise the ultra-violet rays, but I think you will see from this there is no advantage in using such a lens. Remember, however, if you are photographing the spectrum of the electric light, or using it for illuminating a sitter, there is a very great advantage in using quartz. We may use another definite chemical compound in the shape of Iceland spar. I have here a very beautifully worked prism of Iceland spar, which has a definite composition of calcium and carbon, and I dare say that we shall reach very nearly to the same ray limit as we did in the quartz experiment. Iceland spar holds an intermediate position between quartz and glass. It was with such a prism as that that Dr. Huggins took his famous star spectra, and I thought it might interest you to throw one or two of these on the screen. They are very small, but the definition is very beautiful. Many of the black lines in these spectra indicate, probably, hydrogen. It remains to be seen whether Dr. Huggins has attained any advantage in using Iceland spar instead of glass, for if the ultra-violet stellar light is absorbed, as with sunlight, no advantage would be gained. I may mention that he gives the composition of the stars by reference to the spectral lines of well-known elements. One more point is this: Would it be advantageous to use a mirror instead of a lens? There is a great deal to be said about this, particularly in spectroscopy, where we have to examine everything minutely. The material we utilise most easily in the case of a mirror is silver: that is to say, we get a glass mirror, and silver it on the front surface. Now, the question is, does the silver reflect every ray in the same way that quartz would transmit it? Here I have a photograph which should give an answer to that question. The bottom half of the spectrum was taken as reflected from a quartz surface, the top half of the spectrum was reflected from a silver surface, and you will see that at one certain part of the latter the rays are very nearly absent, though beyond that again they are present. Where those rays are wanting is just at the end of the solar spectrum, and therefore, when using sunlight, it is no great advantage to use a quartz reflector over a silver reflector. In spectroscopy it is necessary to know exactly the qualities of all the substances with which you are dealing. One question in photography and in spectroscopy is, what width of slit you would use—what slice of light would you allow to pass through? Here, let me give you a demonstration. In the centre of this black disc there is a fine line of light, and there is a micrometer screw by which we can tell how many thousandths of an inch wide it is. As a rule, about $\frac{1}{600}$in. is the dimension used for ordinary work. I have been referring to the photographs of two spectra on the same plate, and I must show you how it is managed. For this purpose, it is necessary to have an adjunct to the slit, and that is a shutter, which is able to cut off half the slit at one time, and afterwards leave that part open, and close the other half already used. By this means we can get one spectrum adjacent to another. In comparing spectra of different metals with each other, we are able to tell whether we have any two lines coincident one with the other. Photographic spectroscopy is the easiest thing in the world when you know how to do it, but it requires a deal of patience to learn every dodge. As a rule a photographer is a patient man; indeed, there ought to be no class of men who have more patience than photographers; hence spectroscopy should not be difficult to them. Here is another piece of apparatus which is very useful in the spectroscope. It is an apparatus by which you can take a great many spectra on one plate. I need not enter into its details; it is simply a dark slide, which by a rack and pinion motion can be raised, so that the plate gives a fresh surface at each exposure. The only light accessible to the plate comes through an opening of about three-quarters of an inch wide, cut longitudinally in the shade. By this method we can get about sixteen different spectra of different materials on the same plate. Here is another piece of apparatus which is also useful in investigations with photography. It is a slide in which you can expose plates in different gases or liquids—that is to say, in water, in alcohol, in nitrogen, and so on. It is essentially a glass cell which slips into a dark slide especially adapted for it; on the top there is an air-tight junction, which is screwed down, and there are two little tubes, through which you can fill the cell with gas or water, or whatever other material you wish to use. This is very useful in investigating the behaviour of different sensitive salts under different conditions of moisture, pressure, &c. This cell has been used in a great many hundred experiments, and I hope it will be used in a great many more. Those who are going in for spectroscopy should not be without such an apparatus as this, for I do not believe much real investigation can be done without something of the kind. The sensitive salt of silver acts differently when isolated from its atmospheric surroundings, and the only way to ascertain how it does so is to expose it with other surroundings, and to differentiate the results one from another. There is no such thing as a perfect vacuum; you cannot say you expose a plate in vacuo, and, for this reason, I say you have to differentiate between the different media in which you expose a plate, in order to get at the true result which would happen supposing you could expose the plate in vacuo. You saw last time how you could combine a spectrum, by means of a lens, to form white light. Now, I want to show you that it is not impossible to develop a plate in white light. I expose a plate behind a negative to the electric light, and in the cell which is placed in the patch of white light is some developing solution (which is quite colourless). The plate is dipped into it. The image comes out into it, although exposed to white light, without fog, which was supposed to be an impossibility. I have another plate placed behind the same negative. I expose half of that plate for half a minute to the white light on the screen, and the other half to apparent darkness, but in the same position on the screen, for a couple of minutes. The plate on development shows that the half which was exposed to what was presumably white light gives no image, while the half exposed in the dark shows a perfect picture. I daresay many of you have guessed my trick, for it is merely a trick; but for those who have not, I will show you how it is done. It is perfectly easy, by mixing two elements of light of different refrangibility, to produce a colour which, at all events, to our eyes, is a white light. But you must not take it for granted that wherever you can see white light you can photograph with it, because it is quite possible you may not. It is only a trick, but some of these tricks bear fruit in a very practical manner. I will reform white light again, and we will examine it by means of the colour-chart I showed you last time. You will see that when the red is placed in the white light there is blackness—no colour whatever—the yellow looks bright, as does the blue, all the other colours are gone except some few, which are of a nondescript colour. The meaning of it is this: we have simply a combination of yellow and blue, which gives us the appearance of white light. (The blue and yellow rays were shown to be coming through two slits placed at the focussing screen of the camera.) The blue has no power of acting on the iodide or chloride of silver, neither has the yellow, and, therefore, the white light which is made by the combination of those two colours is powerless to act on films made of such materials as those. We can also produce a white light, practically, by a red and green, and if we examine this (which is a very good imitation of white light) in the same way, you will not see the whole series of colours in the colour chart any better than you did before. The red comes out perfectly, but the blue is no longer visible; the blue becomes green, and the violet becomes red; the yellow is also not intense. This is because we have only two colours present, viz., the red and the green. The apparent darkness to which we exposed the one-half of the plate was in reality the dark ultra-violet light, and I need say no more regarding that. I told you last time that this was a very interesting way of studying the spectrum. You see how, by combining two lights together, you may have a light which is perfectly safe for certain salts of silver. On the screen is the spectrum taken on the three ordinary salts of silver—chloride, iodide, and bromide. The iodide stops exactly at the violet. Below that light we have no action whatever, and we, therefore, may expose an iodide plate with impunity to any rays below the the violet. A bromide plate, you see, is sensitive down as far as the yellow, and, therefore, it would be impossible to develop a bromide plate in such a light as I showed you just now, whereas iodide is perfectly capable of being developed in such white light; the chloride again stopped very nearly with the limits of violet, so that it would be safe to develop a chloride plate in such a light.

[*] The substance of the Cantor Lectures delivered before the Society of Arts.

## LAYING OUT SHEET IRON AND BOILER WORK.*

ORDINARILY, a boiler-maker can get along with a knowledge of the first four rules of arithmetic, but I would suggest that with these you acquire a thorough knowledge of square root, as this may be of some advantage to you at some time in your practice. I have had occasion to know this to be true from my own experience. Ability to calculate in decimals is also of great importance, as will readily be seen on looking at the multiplication of fractions; as, for instance, let it be required to multiply 37¼ by 38¾. By the decimal method, these become 37·25, multiplied by 38·75, and the operation becomes one of simple multiplication. The calculation of the circumference from the diameter of a circle is one of the first, simplest, and most essential points in laying out work. In my own practice, I have followed the rule: "As 7 is to 22, so is the diameter to the circumference." In other words, three and one-seventh times the diameter are equal to the circumference. Example:

Diameter, 42in.
3⅐
126
6
132 circumference.

In the books usually sold as assistants to boiler-makers and others, the decimal 3·1416 is given, but the results are so near the 3⅐ theory, and the latter is so much simpler, that I have invariably used it. Taking the other as an example, we have

3·1416
Multiplied by diameter, 42
62832
125664
Equal to 131·9472 .

We here have a difference of

$\frac{428}{10000}$ $\frac{52\frac{1}{2}}{1000}$ $\frac{5\frac{1}{4}}{100}$

or a little over $\frac{1}{20}$th of an inch, and if you look on your rule for the last-named distance, your eyes will be keener than mine if you find it. The rules given, no matter which you use, apply to the circumference of a circle without regard to thickness of plate. If you want to make a large and small course, such as boilers are usually made of, there would necessarily be quite a difference in the length between the inner and outer courses, and to get this you would add three thicknesses of plate to obtain the distance from centre to centre of holes for the length of large course, making it, if of ¼in. plate, 132¾in., and subtract three thicknesses to obtain the distance from centre to centre of holes in the small course, which would leave the latter 131¼in.—a difference of 1½in. this case. In $\frac{5}{16}$in. iron I have allowed a difference of 2in. between the large and small courses, adding 1in. for large and subtracting the same quantity for small. In ⅜in. plate I allow six and a-half thicknesses, and $\frac{7}{16}$in. and over I allow seven thicknesses of plate between the large and small courses. In ¼in. iron, and under, six thicknesses are the standard used by me, and I have found good results from their use. These figures do not make any allowance for laps, which must be added to the length already given, as I have stated the distance only between the centres of holes. In single-riveted work, three times the diameter of rivet equals the distance from centre to centre; twice the thickness of plate is supposed to equal the diameter of rivet; and one and one-half times the diameter of rivet is the lap, or distance from caulking edge to centre of hole. In the rule last given, I say twice the thickness of plate is supposed to equal diameter of rivet. In these days of heavy plate the diameter of rivet, if carried out in this proportion, would, in many cases, prove injurious; as, for instance, a ¾in. shell would require a rivet 1½in. in diameter, and three diameters of that equals 4½in. between centres of rivets. I can fancy the smiles on some faces as they think of caulking that distance, and making tight work to carry a pressure of 150 pounds to the square inch. Tight work can and has been made by this method, but the practice of engineers and boiler-makers at present is to use smaller rivets and reduce the distance between centres, at the same time taking into consideration that the greater the number of holes the more the plate is weakened. While on the subject of calculation, I would also say that in figuring up the circumference by the 3⅐ rule, where there is a fraction left, as, for instance, ⅐ of 44, which equals 6²⁄₇, my practice is to call the fraction ²⁄₈ or ¼, which can be found on any rule, while the ⅐th of an inch is never met with on the 24in. rules used by boiler-makers.

---

* Abridged from an article by G. Marshall in the *American Machinist.*

## EVOLUTION IN THE VEGETABLE KINGDOM.*

THE law of biologic evolution (for it is no longer a mere "doctrine") may be regarded as fairly established, no large and respectable body of scientific men being any longer found to oppose it when stated in its most general form, while difference of opinion and discussion have narrowed down to the more special aspects and minor details. In the animal kingdom, where organisation is generally so high and structure so definite, great progress has been made in discovering the particular lines along which development has taken place, and something like a true genealogy of the existing types has been worked out. The law of phytogeny is abundantly established by palæontology and surprisingly confirmed by embryological ontogeny.

In the vegetable kingdom this last important class of evidence is almost wholly wanting, and palæontological evidence, owing to the lower structural rank of plants, is far less complete and convincing than in the animal.

It is proposed in this article briefly to inquire what vegetable palæontology has to present in favour of evolution in plants. The subject may be considered under three somewhat distinct points of view, the historical, the geological, and the botanical.

### I. Historical View.

It is a common observation that botany is far behind zoology in supporting advanced biological theories. This is still more strikingly true of the study of extinct than of that of living forms, for not only were the ancients wholly unacquainted with any form of vegetable petrifaction, although familiar with fossil shells, madrepores, and other animal remains, but when at last the era of science dawned toward the close of the eighteenth century Blumenbach had for many years been sounding the key-note of palæontological truth in the animal kingdom before Schlotheim took up the refrain in favour of plants.

When we consider the present state of knowledge respecting the geological strata of the earth's crust, we can scarcely realise that but two generations ago comparatively nothing was known on this subject. Geology was not yet born. The investigators of the last century were really not discussing the geologic age of fossil remains. With those who studied fossil plants the assumption was universal that they were plants that grew somewhere in the world only a few thousand years ago at most, plants such as either grew then in the countries where their remains were found, or in other countries from which they had been brought by one agency or another, generally that of the Flood, or else, as some finally conceived, had been destroyed by these agencies, so as to have no exact living representatives.

In the year 1804 appeared Baron von Schlotheim's "Flora der Vorwelt," as it is now universally quoted, although the author himself merely entitled it a "description of remarkable plant impressions and petrifactions—a contribution to the flora of the former (or primeval) world." To us this seems modest enough, but, in view of the history of palæontology, the second part of this title amounted to a bold declaration, and accordingly we find him defending it in his introduction by these words: "The petrifactions which so early engaged the attention of investigators, and which, without doubt, afforded one of the first incentives to the founding of mineral collections and to the earnest study of mineralogy and geology, have, as is well known, since Walch began to arrange them systematically, been for a long time, as well in as out of Germany, almost wholly neglected. They were content to regard them as incontestable proofs of the Deluge, which closed all further investigation until they were at last compelled to explain their occurrence through other great natural operations which had probably been going on earlier and more universally than the flood described in the Bible, and influencing the formation of the upper strata of the earth's crust; and more recent observations and investigations have even led us to the very probable supposition that they may be the remains of an earlier so-called pre-Adamitic creation, the originals of which are now no longer to be found. * * * In the continued investigation of this subject this opinion, with certain restrictions, has, in fact, gained a high degree of probability with the author of the present work, so that he ventures to announce his treatise as a contribution to the flora of the ancient world (Vorwelt)." Since its introduction by Schlotheim this expression, "Flora der Vorwelt," has been applied to nearly all the German works on fossil plants, and "Beitrage zur Flora der Vorwelt" still continue to appear.

This work was followed, though sixteen years later, by his "Petrefactenkunde," and also by Count Sternberg's important "attempt at a geognostico-botanical presentation of the flora of the ancient world." These men were the pioneers of vegetable palæontology. It was reserved for Adolphe Brongniart to become its true founder. Brongniart's paper on the classification and distribution of fossil plants, which was published in the memoirs of the Paris Museum of Natural History in 1822, showed that he had already been some time at work, and after six years of nearly complete silence he at length came forward, in 1828, with his epoch-making works on the history of fossil plants—the "Prodrome" and the "Histoire des Végétaux Fossils"—which, taken together, as was the design, form the solid basis upon which the science has been erected.

Brongniart's fundamental conception was that fossil plants were none the less plants, and that so fast as they really became known they should be placed in their proper position in the vegetable series and made to form an integral part of the science of botany. In his classification he therefore had due respect for the natural system as then understood, but he nevertheless felt that geognostic considerations must be taken into the account, and he saw with almost prophetic vision that in passing up through the geologic series higher and higher forms of vegetable life presented themselves Although unable to understand the complete continuity in the series, as modern evolution postulates, and although affected by the Cuvierian idea of successive destructions and re-creations, still he insisted that each successive creation was superior to the one it had replaced, and that there had thus been, as it were, a steady progress from the lowest to the highest forms of vegetation. He divided the geologic series into four great periods, the first extending through the Carboniferous and corresponding to the modern Palæozoic, the second embracing the Grès bigarré, or Buntersandstein, only, the third seeming to include the rest of the Trias, the Jurassic, and the Cretaceous, and the fourth completing the series. The table which he gives on p. 219 of the "Prodrome" is designed to show the development of the higher types of vegetation in successively higher strata, and in discussing it he remarks that "in the first period there exist hardly anything but cryptogams, plants having a more simple structure than that of the following classes. In the second period the number of the two following classes become proportionately greater. During the third period it is the gymnosperms which specially predominate. This class of plants may be considered *intermediate between the cryptogams and the true phanerogams* (dicotyledons) which preponderate during the fourth period." The words italicised in the liberal translation here made are scarcely less than a prophecy, and one whose fulfilment is only now being tardily granted by systematic botanists.

---

* By Lester F. Ward, A.M., in the *American Naturalist.*

As the result of his prolonged studies, Brongniart finally arrived at the following remarkable classification of plants, as drawn up on page 11 of the "Prodome" and repeated on page 20 of the "Histoire:"—I. Agams. II. Cellular cryptogams. III. Vascular cryptogams. IV. Gymnospermous phanerogams. V. Monocotyledonous angiospermous phanerogams. VI. Dicotyledonous angiospermous phanerogams.

In the present state of botanical science Brongniart's "agams" would probably all be relegated to his second group, or cellular cryptogams, but in other respects this classification is pre-eminently sound, and seems likely to be vindicated by the future progress of science.

It will thus be seen that Brongniart founded the science of vegetable palæontology firmly upon the law of progressive development, and there can be little doubt that if his influence could have been felt by botanists as it was by vegetable palæontologists in general, botany might have advanced *pari passu* with zoology. But Brongniart was far in advance of his time, and his views were destined to meet with violent opposition. His method was, with few exceptions, adopted by subsequent palæobotanists, but never by botanists proper.

(*To be continued.*)

**Science and Art Examinations, 1885.**—The following are the successful candidates for Royal Exhibitions, National Scholarships, and Free Studentships in 1885:—William Burton, 22, science teacher, Manchester, National Scholarship; Philip L. Gray, 19, assistant master, Southampton, National Scholarship; Charles Lang, 22, engineer, Johnstone, N.B., National Scholarship; Thomas Clarkson, 20, engineer, Pendleton, Manchester, National Scholarship; Harry E. Hadley, 18, student, Worcester, Royal Exhibition; William Scudamore, 16, student, Northampton, National Scholarship; Frederic W. Lanchester, 16, architect's assistant, Southampton, National Scholarship; Thomas H. Holland, 16, student, Helston, National Scholarship; Harold E. Hay, 14, student, Manchester, National Scholarship; William Blackmore, 18, student, Sheffield, National Scholarship; Hugh O. Bennie, 20, engineer, Glasgow, Royal Exhibition; William Kelsall, 17, student, Bradford, National Scholarship; Henry Sowerbutts, 17, student, Manchester, National Scholarship; Frederick Chattaway, 24, chemist, Birmingham, National Scholarship; James Young, 23, shoemaker, Belfast, Royal Exhibition; Arthur J. Moulton, 20, engineer's apprentice, Preston, Royal Exhibition; Harold C. Coote, 17, student, London, Royal Exhibition; Robert H. Unsworth, 20, engineer, Pendleton, Manchester, Royal Exhibition; Sidney H. Woolhouse, 15, student, Weaste, Manchester, Royal Exhibition; David Wilkinson, 21, agent, Preston, Free Studentship; Henry P. Motteram, 19, student, Small Heath, Birmingham, Free Studentship; Albert E. Briscoe, 17, machinist, Birmingham, Free Studentship; Orlando J. Preston, 16, student, Bristol, Free Studentship; James McKenzie, 20, engineer, Glasgow, Free Studentship; Philip C. Coultas, 18, student, Bristol, Free Studentship.

# SCIENTIFIC NEWS.

THE death is announced of Thomas Box, the author of, amongst others, those well-known works, "A Practical Treatise on Heat," and "A Practical Treatise on Mill-Gearing, Wheels, Shafts, Riggers," &c. Mr. Box was, we believe, in his sixty-fifth year.

Many will regret to hear of the death of the well-known antiquary, William John Thoms, F.S.A., at the age of 82. Mr. Thoms was well known in literary circles, and more widely by his work on the "Longevity of Man." Within recent years he has seen reason to modify his opinion that cases of centenarianism are very rare, and many friends will regret that he did not live to refute his opinions in his own person.

In No. 2,676 of the *Astronomische Nachrichten* Dr. Lamb has a note of an investigation of the annular parallax of a small star in Draco, to which attention was attracted by its large proper motion. It is a double star, numbered 2,398 in Struve's Catalogue, and its components have magnitudes, respectively, of 8·2 and 8·7. According to Dr. Lamb, the annual parallax of the principal star amounts to ·34″.

On any Tuesday, Thursday, or Saturday, until the end of September, those who have archæological tastes may visit the rooms of the Royal Archæological Society, Oxford-mansions, Regent-circus, and see the large and interesting collection of antiquities which Mr. W. M. Flinders Petrie has discovered and brought from Egypt—from the Nebireh mound, which is the site of the famous Greek city, Naucratis. An iron foundry appears to have been discovered, and a number of tools of various kinds, besides that novelty in archæological "finds"—fishhooks. The iron foundry would appear to have been at work in the sixth century before Christ.

A royal charter has been granted to the Entomological Society of London, which was founded in 1833.

It is stated that Prof. Huxley, P.R.S., will continue to act as Dean of the Normal School of Science and Royal School of Mines, South Kensington, by special request.

The *Athenæum* says:—"A good deal of surprise has been excited in the scientific world by the action of the Science and Art Department in relation to the chair of biology vacant at the School of Science at South Kensington, by Prof. Huxley's resignation. This professorship was recently put on a firm footing by a Treasury minute, and, being worth £800 a year, might be considered one of the few prizes open to biologists. The Treasury minute, too, in fixing the salary, spoke of the desirability of encouraging original research; but such encouragement as this chair gave has disappeared, for the appointment has been summarily suppressed. The salary of Mr. Howes, Prof. Huxley's assistant, has been raised from £200 to £600 a year; but this is scarcely considered compensation for the abolition of the professorship."

The report of Drs. Klein and Gibbes on the alleged discovery that cholera is due to Koch's comma bacillus will be withheld until the conclusions of the committee appointed by the Secretary of State for India are also ready.

The autumn meeting of the Iron and Steel Institute will be held at Glasgow from the 1st to the 5th of September. The programme contains a series of ten papers bearing upon almost every subject of current interest to iron metallurgists, the more notable being on the "Rise and Progress of the Scotch Steel Trade," by Mr. Riley, and on the "Present Position and Prospects of Processes for the Recovery of Tar and Ammonia from Blast Furnaces," by Mr. William Jones, both of Glasgow. A committee composed of over 200 gentlemen engaged more or less intimately in the manufacturing industries of the west of Scotland has been formed in Glasgow for the reception and entertainment of the Institute, and excursions have been arranged to all the leading works and places of interest in the neighbourhood during the five days of the meeting. The 4th of September is to be entirely devoted to an excursion to Inverary Castle, the Duke of Argyll's seat, while on the following day an excursion will be made to the works of the Forth Bridge, which will terminate the week's proceedings.

M. Hippolyte Fontaine says he is quite convinced that in the present state of knowledge regarding the construction of electrical machines, it is practically impossible to transmit 100 h.p. with a single generator dynamo through a resistance of 100 ohms even for one hour. The Creil experiments of M. Marcel Deprez cannot, therefore, in his opinion, be carried out under the conditions laid down. They are as impossible to realise as would be a steam-engine working at a pressure of 500 atmospheres.

The Rhode Island Electric Power Company, operating under the Daft system, are running a 10 h.p. generator at Providence, and furnishing power for the forges and atmospheric hammer in the engine works of the Harris-Corliss Company, the Rhode Island Printing Company, and the Hope Glass-Cutting Works, and in each case giving absolute satisfaction. They are making preparations to put in a 50 h.p. generator.

Prof. William A. Anthony, of Cornell University, Ithaca, New York, has constructed the largest galvanometer in the world. There are four circles, each two mètres in diameter. Dr. Guyter and several electrical engineers are engaged in testing, by the aid of the galvanometer, the strength of the current of a powerful dynamo run at 1,200 revolutions in a minute.

At the meeting of the French Association held at Grenoble M. Chauveau said that there was much reason to regard with interest the researches of Dr. Ferran on cholera inoculation—an opinion which derives such importance as it possesses from the fact that M. Chauveau is recognised as an authority on pathogenic microbes. M. de Mortillet discussed the question of tertiary man, and stated that the problem was not to discover the prototype of existing man, but only an ancestral form—a predecessor of the man of historical times. To the question, Do there exist in the tertiary strata objects which imply the existence of an intelligent being? M. de Mortillet replies in the affirmative. He declares that there is sufficient evidence to show that animals less intelligent than man, but more intelligent than existing apes, lived during the tertiary period. The anthropethique, or ape-man, was an ancestral form of historic man, whose skeleton has not yet been discovered. The almost unanimous opinion of the meeting was that there can no longer be any doubt of the existence of ancestrel man in the tertiary period.

Baron Leon de Lenval, of Nice, has offered a prize of 3,000 francs (£120) for the best easily-carried instrument for the improvement of hearing in cases of partial deafness. The instrument is to be constructed on the principle of the microphone, and must be completely finished and sent in before the end of 1887. The award will be made at the International Congress for Otology, held in September, 1888, at Brussels.

Prof. Lustig, of Hanover, in the course of investigations having for their object the discovery of the pathogenic microbe of contagious pneumonia of bovine animals, has isolated, in pure cultures, four varieties. One is a bacillus that liquefies gelatine and forms at the confines of the liquefied area pulverulent masses of a whitish-grey colour. The liquefied gelatine varies in tint dependent upon the proportion in which the other varieties of microbes are present. The second microbe is a micrococcus which does not liquefy gelatine, and forms at the surface a deposit something like the white of an egg in appearance; the gelatine is gradually absorbed as this cultivation proceeds. The third is also a micrococcus, very like the preceding, only that it forms golden-coloured clusters. The fourth is micrococcal in form, and appears as coloured heaps of a yellowish-orange tint, having a waxy look on the surface of the gelatine. It does not liquefy the medium, and grows better on potatoes. Inoculations made on a heifer gave mostly negative results.

**Artificial Honey.**—One of the latest American novelties is artificial honey—that is, honey adulterated with a syrup manufactured from maize, the method being as yet a secret. Experiments on the subject show, however, that if wheat or maize starch (not potato starch) be treated with oxalic acid, or any other powerful organic acid, a syrup is produced which in a certain concentration, and after standing two or three weeks, exactly resembles in taste and appearance an old honey.

# LETTERS TO THE EDITOR.

## DOUBLE STARS.

[24627.]—Clouds having prevailed for some time after Mr. Sadler's letter (24474, p. 488) was published, I have been unable to look again at the double in Corona Borealis, and, when it cleared, the star was hidden before dark among the top branches of a tree whose trunk is only 13ft. from my telescope in a W.S.W. direction. I am inclined, however, to believe it is no other than Σ. 1959, though I cannot account for the difference in magnitude. My declination circle was right, but my reading was wrong.

I have looked at the stars Mr. Sadler kindly gave in the same letter, but in such conditions of air that to obtain a disc I have had to reduce my aperture down to 6in., and even then the stars were far from being steady and clear; it is, therefore, with the greatest diffidence I give the following results, which are the mean of three nights: B.A.C. 6959 (A.C. 17) Pos. = 260° 44 Cygni (A.C. 18) 300° 60 Cygni (OΣ. 426) 150° P xxi. 215 Cygni (β. 167) 80° 75 Cygni (A.C. 20) 208°. I feel that to deal successfully with such stars very good air is absolutely necessary, especially when a reflecting telescope is used, as even then there is always, in a more or less marked degree, a certain measure of scattered light around the minute central disc which must hide or extinguish such small stars as Struve's 11th mag. I hope Mr. Sadler will say as soon as possible how far I am wrong, as I intend to observe these stars again.

I may say I have given Mr. Burnham (letter 24591) the trouble of looking for the double in Corona Borealis. He will see by a subsequent letter of mine that the first position given was wrong. What is the mag. of β. 54 in Σ. scale? I find it easy, especially with high powers.

August 14. **C. M. Gaudibert.**

## PLACES OF STARS—36 OPHIUCHI—SIZE OF BEER AND MÄDLER'S TELESCOPE.

[24628.]—The following are the places for January 1st, 1885, of the objects referred to by Mr. Ruthven (query 57186, page 507):—

| | H. | M. | S. | ° | ′ | ″ | |
|---|---|---|---|---|---|---|---|
| T. Coronæ | 15 | 54 | 41·6 | + 26 | 14 | 48 | (Greenwich 9-year Cat.) |
| B.A.C. 6624 | 19 | 15 | 7·3 | + 40 | 8 | 55 | (B.A.C.) |
| B.A.C. 7001 | 20 | 14 | 46·3 | + 38 | 38 | 40 | „ |
| B.A.C. 7219 | 20 | 43 | 23·6 | + 45 | 6 | 27 | „ |
| Σ Neb. 6 | 18 | 6 | 31·3 | + 6 | 49 | 42 | (Schultz) |
| H. 5122 | 19 | 16 | 44·7 | − 18 | 13 | 8 | (Œltzen-Arg. S.) |
| β 142 | 19 | 21 | 47·0 | − 12 | 22 | 16 | (Schjellerup) |
| H. 1470 | 19 | 59 | 30·2 | + 37 | 59 | 58 | (Lalande) |
| Birm. 658 | 23 | 55 | 23·9 | + 59 | 42 | 55 | (Œltzen-Arg. N.) |

I think myself it is a pity that the R.A.'s, in the fourth edition of "Cel. Objects" are not given to the nearest second of time, as they were in the third; or, at least, to the nearest tenth of a minute. The supposed variability of the components of 36 Ophiuchi, alluded to by Mr. Numsen (letter 24492, page 518), rests only on the estimates of Smyth, which are utterly at variance with those of other observers (Herschel at the Cape, Dawes, &c.) at the same epochs. I regret to be obliged to contradict Mr. W. C. Rogers (letter 24596, page 519) as to the aperture of the telescope mounted by W. Beer in his villa near Berlin, and which was employed in making the drawings of Mars given in No. 191 of the '*Astronomische Nachrichten.* It was a refractor of 3¾in. aperture, not 3in., and of 54in. focus, mounted equatorially, and driven by clockwork. **H. Sadler.**

## 53 OPHIUCHI.

[24629.]—As there has been some correspondence of late in "Ours" as to the stars visible in the field with 53 Ophiuchi, I send a rough sketch of the field with a power of 100 on my 5¼ Calver. I may add that these are numbered according to their brightness; but there are a great number of smaller stars which can only be glimpsed in the field. I may also say that I have no means of determining the exact distances or positions. The sketch was made by eye alone, and, of course, at the telescope. My mirror is not in first-rate order, or I could possibly have steadily held others which were only glimpsed.

NUMBERED ACCORDING TO BRIGHTNESS

Norwich, Aug. 12. **Easy.**

## 36 OPHIUCHI.

[24630.]—With reference to Mr. Numsen's remarks about 36 Ophiuchi (letter (24592), I quote the following from my little book ("Southern Stellar Objects"): "Both yellow, and almost exactly equal. The *f* star, if anything, rather the brighter of the two. In the field *n.p.* is a 7½m. or 8m. star, to which I see a faint *comes* to the south, 3m., 1875. Smyth says: 'The principal star is thought to be variable, though I have always seen it as now registered' (4½m., 6½m.), and he calls the companion to 7½m. 'a most minute *comes*,' whose existence Sir John Herschel first pointed out to him. In a large field, with 36 Ophiuchi, is the star 30 Scorpii. Between the two, Smyth (Cel. Cycle) notes a 14m. star. Close to the place indicated by Smyth (in a diagram) I see steadily with 3in. a small star; other faint stars in the field."

The above observations were made in Northern India. I think it very probable that one of the components of 36 is really variable. It will be seen that Mr. Numsen's observation differs from mine with regard to their relative brightness.

**J. E. Gore.**

## THE DAYLIGHT OCCULTATION OF ALDEBARAN.

[24631.]—I am very unwilling to enter into a controversy on scientific details; but Mr. Peek's letter of August 7th requires a reply, and with that I trust the correspondence on the subject may cease.

Mr. Peek says he is aware that "the times of immersion and emersion will vary perceptibly at places in different geographical positions," and he adds, that it is this very difference in time from Greenwich, obtained by observation, which is so valuable to the traveller in enabling him to compute his longitude."

But Mr. Peek ought to be aware that the amount of this "difference in time from Greenwich" thus obtained from observation depends on two things, and not on one only. It depends, first, on the difference of longitude, we admit; but it depends, secondly, on the difference of latitude as well. The difference of longitude and latitude between two places causes the moon to occupy a different position in reference to the star as seen from each place; and this difference (due to the moon's parallax) causes also a difference in the times of immersion and emersion. Nothing but a separate calculation for each place can determine its amount, and to do this expeditiously is the object of the "partially-graphic method of eclipses and occultations" which I have submitted to your readers.

If Mr. Peek is still unconvinced, I have done with him; but with reference to the last paragraph in his letter, allow me to say that though I do not lay claim to any very unusual acquaintance with the science of astronomy, this, at least, is one branch of it, in which I do claim to be thoroughly versed; nor does this statement depend simply on my own *ipse dixit*, but my position in the mathematical tripos at Cambridge in 1848 in the opinion of most people would justify the assertion.

**James Pearson, M.A., F.R.A.S.**

Fleetwood Vicarage, Aug. 14.

## THE CASSEGRAIN.

[24632.]—In thanking "Orderic Vital" for his reply, I should like to carry the problem somewhat farther if he would deal with it in the manner suggested, the ultimate object being to obtain the equivalent Newtonian focus of any given Gregorian or Cassegrain. Let me put the matter in the shape of four propositions, so as to render my meaning clear.

1. If the solar foci of the two mirrors are known, the focus of the small mirror for the vergent rays from the great mirror can be directly determined.

2. If the two mirrors are so matched as to be free from aberration for parallel rays, they can only produce a perfect (stellar) image at the final focus when placed a certain definite distance apart.

3. The distance apart of the mirrors being thus a fixed quantity, the position of the final focus will also be fixed.

4. The position of the final focus being fixed, the equivalent Newtonian focal length can be absolutely determined from the focal lengths and positions of the mirrors and their foci.

As regards proposition No. 2, the formulæ of "Orderic Vital" and Dr. Royston-Pigott are rendered more complicated by the assumed variability of the distance C E in Fig. 2, page 380, whereas, if I am not mistaken, *no variation is possible* when we are dealing with parallel rays and curves so matched as to be free from aberration. It would follow from this that Dr. R.-P.'s table giving the variation in position of final focus due to variations in the separation of the mirrors is only true for parallel rays when aberration is neglected; but for near objects is approximately correct. I say approximately, because it would seem that if the mirrors are figured so as to be true for the parallel rays of celestial objects, they cannot be true for the diverging rays from terrestrial ones; and though by varying their distance apart we may bring the rays more accurately into focus, we cannot, of course, alter the curves of the mirrors themselves to correct the aberration produced by this change in their relative positions. Coming to proposition No. 4, I showed in a former volume of the "E. M." that we could obtain the (approximate) equivalent Newtonian focal length by the formula there given —viz.: $N = \frac{F}{f}(F \pm f + \Delta)$, the positive sign being used for the Gregorian and the negative for the Cassegrain. In this F and $f$ are the foci of the mirrors, and Δ the distance of the final focus behind the vertex of the large mirror.

In these formulæ (deduced from a diagram) the points C and E of Fig. 2 on p. 380 were taken as coincident—that is to say, the difference between the solar focus and the focus for the vergent rays actually received by the small mirror was neglected. I presume, however, that by substituting the actual for the solar focus (as regards the *f* in the formulæ), the result would be exact instead of approximate.

The several steps for determining N would, therefore, be as follows:—From F and *f*, the solar foci, determine the focus of *f* for vergent rays; call it $f^1$ for distinction. Then $F + f^1$ will be the distance apart of the mirrors. Having the distance of the mirrors apart, fix the position of the final focus by "Orderic Vital's" rule on p. 519. This point being fixed, we also know its distance △ behind the great mirror, and have, therefore, all the elements for determining N.

In many respects this method of dealing with the problem seems simpler than the treatment of either "Orderic Vital" or Dr. Royston-Pigott, and for a non-mathematician like myself would be easier to use in any given case.

As to the two parabolic mirrors with foci coincident, they would merely serve as light collectors, and not as image-formers; but we may go a step further. Suppose while the vertex of the small mirrors remains in the same position relatively to the large one that its curve gradually changes from a parabola to an ellipse, then the infinite distance at which the parabolic curve would (theoretically) form an image becomes continually reduced till the point is reached where the second focus of the ellipse is situated, which is conjugate to the focus that coincides with the focus of the large mirror, and at this point an image is formed free from aberration.

But (and this is the point I am driving at) if such is the case, it is essential that one focus of the ellipse should coincide with the focus of the large mirror, a condition which Dr. Royston-Pigott expressly stated was non-essential.

Of course the distance from vertex of small mirror to the common focus of the two will not be the same as if the small mirror were subjected to parallel rays, and in that respect it differs from the parabolic small mirror first referred to. In this instance I use the Gregorian as an illustration; but, *mutatis mutandis*, the same reasoning would apply to a Cassegrain.

**A. S. L.**

## THIGH-BONE OF A SAURIAN—"SAURIAN" WATER LIZARD, OR CROCODILE.

[24633.]—In the Natural History Museum, South Kensington, there is a thigh-bone of crocodile (recent) not much larger than a goose leg bone, or as near 7in. long as may be seen. This bone belonged to a crocodile measuring 18ft. from nose to tail, and seems out of all proportion for walking purposes, especially for turning round sharp corners with so long a body, yet better adapted to propel through or under water. Now, in the same glass case is a fossil thigh-bone of a giant saurian 7ft. long, perhaps more, and thick in proportion. This belonged to a fearful creation 216ft. in length. Where is the thoroughfare in London wide enough to allow this immense crocodile to turn down a side street? I suppose his mouth or jaw would be 30ft. long, and his girth 60ft. round; and all this came out of an egg. Haeckel did not believe in a miraculous creation (special); but was not this saurian a distinct creation, now fortunately extinct as a dead leaf separated from the tree? What tree? The visible Universe. Haeckel took the envelope off Nature, and laid bare the secret of the continuation of Life (what I should term the origin of life) in a more certain manner than any other physiologist, for he went to the centre, the inside of the egg, to discover the reason why.

In his diagram, he places the centre in a mass of protoplasm, not in the middle, but in a hemisphere or upper part; and in this centre in the process of evolution he finds a kernel, and in this kernel a seed, all of which presently resolve themselves into centres having kernels and seeds to develop, until the whole mass is filled to repletion, after which changes take place in the primary formation of bodies, which ultimately become changed into different forms of vegetable and animal life. This appears to me most miraculous, for while the mass is sustaining itself by drawing in the outer surrounding substance, the centre is evolving from itself, and is thus the origin of life in the individual.

I do not attempt to account for the great saurian's thigh-bone, and neither do I think it necessary to knowledge to study these alone, because the truth is more likely to be found in minutiæ. "Perfection is made up of imperfections." The largest skeleton I have any recollection of was that of a whale (rorqual), about forty years back, when I took 300 youngsters in and out of its vertebrate form. The last I heard of it was its sale to a Russian, who took it home with him. By way of contrast, a skeleton of a mouse was perched by the side of one of the ribs.

There are still some large fish (cetacei) left, and little minnows as well, who manage to live as in antediluvial times, when some of the cave men carved their likeness on horns, teeth, &c. Were they white or black men, or when did they begin to change colour?

**Fiddler.**

## SULPHATE OF SODA IN DANIELL'S BATTERY.

[24634.]—In the letter which you did me the favour of inserting last week on this subject, I see that I spoke of the transmission of molecules of $SO_3$ from the sulphate of copper to the zinc. Your chemical readers would at once perceive that I ought to have said $SO_4$, this being the "radical" alike of sulphuric acid, $H_2SO_4$, and of the three salts with which we are at present concerned, formed by substituting copper, zinc, and sodium respectively for the hydrogen of the acid.

Perhaps my comparison of the strength of the current when the dilute acid and the sulphate of soda were respectively used was not quite conclusive, as I used a galvanometer of high resistance.

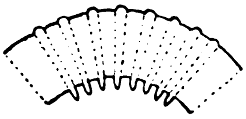
**Abner E. Brown.**

Wadenhoe, Oundle.

## A CURIOUS STOVE.

[24635.]—Stove pipes of this description (letter 24604), are very common, not only in Switzerland, but also in Germany and France. The form of the convolutions varies according to the fancy of the workman and the space at disposal, the object being to economise fuel by securing as much heating surface as possible inside the room. The bends are made in a very ingenious way; but though resembling at first sight the "lobster-back," as stated, they are found on closer inspection to differ widely from it, each quadrant consisting of a single piece of sheet iron, whereas the "lobster-back" is made up of separate segments seamed or soldered together.

The annexed rough sketch shows one of these bends in section, by which it will be seen that a length of pipe is drawn into this shape by means of a series of corrugations, which are wide and shallow on the outside, but deep and narrow on the inner side of the bend. I have not been able to obtain bends of this make in England, the nearest thing to be had being the so-called "circular stove-pipe elbow," which is made in two pieces, and is in all respects inferior to those in question. There should, however, be no difficulty in obtaining them from abroad, seeing that they are an article in common use, and, therefore, kept in stock by such houses as ordinarily deal in metal ware. I happened to be in Switzerland last week, and whilst looking over the premises of the well-known iron merchants, Rauch and Cie, at Fribourg, saw large quantities of these bends stacked in one of their warehouses. From memory I should say that the smallest was about 10c.m., or nearly 4in., though smaller sizes than this are frequently seen in use in connection with rain-water pipes, &c.



At the Paris Exhibition of 1878 numerous specimens of pipe bends made in this way, out of iron, zinc, and copper, from 1½in. diameter and upwards, were shown by various makers in classes 27 and 43.

**R. T. Lewis.**

## AN ADJUSTABLE OBJECT-GLASS FOR TELESCOPES.—II.

[24636.]—In the telescope spoken of in the last letter on the subject, the aperture is 3½in., and the focal length about 44. On trial, however, I find that on ordinary nights the best aperture is 3in. I had supposed that as the spherical aberration might be so very accurately corrected by adjustment of the distance between the lenses, we might use a larger aperture. But, as "Prismatique" suggested at the time, although we may by this method make the aberration to be absolutely zero for any proposed line of the spectrum, we cannot do so for all of them simultaneously (see note), so that in the correction for spherical aberration there will always be something analogous to the secondary spectrum in colour correction. And to this may be added that the lateral spherical aberration varies for a given value of *f* as the cube of the aperture, so that the necessarily uncorrected aberration increases rapidly as the aperture does. Hence, we must look upon this part of the experiment as unsuccessful, in that it is not worth while to depart from the usual relation for the sake of any advantage that may be obtained on exceptional evenings.

Moreover, there seems to be some other and less obvious cause, for, on looking with full aperture on bright objects—Jupiter, Arcturus, &c.—there is a small amount of glare or diffused light surrounding the object; and this in the case of the moon tends to slightly impair the definition, in that the diffused light which would arise from a given part of it, if detached from the rest, spreads itself over the surface of the whole, to the detriment of definition.

But on contracting the aperture to 3in., the glare above mentioned entirely disappears, and the view of the moon, for crispness and clearness of detail, was quite exquisite. The appearance of Jupiter, too, was very good. Saturn I have not seen; but "Prismatique" tells me that when he was trying it the shadow of the rings on the planet was well seen, as also Ball's division of the rings, all round.

On Aug. 14 the evening was a little hazy, just such a one as is favourable to definition, and with full aperture the star discs were remarkably neat and well-defined, and the optical appendages generally remarkably small. I hope on another occasion to say something of the performance on close doubles.

Note.—This may throw some light upon what Mr. Franks observes: that very large telescopes will not bear such deep eyepieces as moderate-sized ones will. For the circle of least spherical aberration varying as $\frac{y^3}{f^2}$, and in similar telescopes *y* varying as *f*, the circle varies as *y*, or, therefore, as *f*. In the same way the circle of chromatic aberration varies as aperture, and, therefore, in similar telescopes it varies as their focal length. This being the case, then, with both aberrations, there will be an indistinctness prepared in proportion to the magnifying power. In fact, it is impossible to magnify without producing indistinctness, and so the magnified object is never so distinct as the object itself. As for the reason why very small telescopes will not bear a high power, it appears to be an accident attaching to each particular instrument. If I remember rightly, "F.R.A.S." told us that opticians did not generally take near so much care in the making of terrestrial as they do for celestial instruments. Hence they have more imperfections, and will not bear so much magnifying.

**W. G. Penny.**

(*To be continued.*)

## MICROSCOPIC.

[24637.]—It is very easy to make glass globules for microscopic use of ordinary glass; Mr. Hooke's "Venice glass" is not at all essential. The difficulty is in using them as microscopes; for, made in the manner described by "F.R.A.S." (of which I was previously aware), they are of such small focal length that the magnifying power is very great. I have mounted some, varying from 1-80in. to 1-100in. focal length, giving powers of 800 to 1,000 diameters. But, besides the instrumental difficulty of focal adjustment for such small lenses (which I have surmounted), the light of so small a pencil of rays is quite inadequate, except with what I may call "violent" illumination. I could see with scarcely any definition an object with the 1-100in., except when it was turned against the sky in the neighbourhood of the sun, or in the opportunity of a setting sun, against the sun itself. Then, however, with its magnifying power of 1,000 diameters I found the definition did not fail.

But lenses by melting glass may be made to much better purpose of more useful focal lengths—not globular—but double convex lenses, in the following manner, which, I believe, is new, or was so when I first made them, say 30 or 40 years ago. Take a bit of fine binding wire, iron (not brass or copper), make, by twisting it round a taper wire for mandrel, a nicely circular loop; flatten it so that the loop is all in one true plane. The loop may vary in diameter from any desired smallness up to ½in. (which is nearly the largest size my glass-melting apparatus will conveniently manage). Place a square piece of glass—thicker or thinner, according as it is desired to have a lens of more or less convexity, but large enough to completely cover the loop. Then, holding it in a suitable blowpipe plane (which should be a vertical, not a horizontal one), the glass assumes in melting a doubly-convex lenticular form. A form, moreover, in which the spherical aberration of a globule tends to be corrected, and a larger proportion of the field is flatter than it is with an ordinary double convex lens. What the exact curve may be, I am not mathematician enough to say. "Catenary" suggests itself. But the factors, gravity, the viscosity of the glass in its approach, still considerably distant from fluidity, with a tendency to "wet" and adhere aggressively to the iron wire, are obscure, and were said by a competent mathematician, of whom I formerly inquired, to be very complicated and beyond his calculation.

Such lenses are made in a few minutes, and perform most admirably when a suitable instrumental apparatus is used. Of such, I have made perhaps fifty or more different forms; and among them the very one which "F.R.A.S." suggests as an application to my V-microscope of a glass lens. I did not, by the way, at all pretend to have discovered the microscopic qualification of a water globule;

but to have contrived a very simple and ready mode of practically applying them.

If "F.R.A.S." will do me the favour to inform me of his address, it would give me pleasure to send him some specimens of these melted glass lenses. And if he, or any other of your correspondents, could define the curvature which, under the circumstances, the glass will assume, I should be grateful for the information.

**J. Hippesley.**

Stoneaston Park, Aug. 15.

## THE MIDLAND 19in. CYLINDER EXPRESS ENGINES.

[24638.]—I am sorry still to see unfavourable accounts of the new Midland express engines with 19in. cylinders. When I left England at the end of last March, I hoped and believed that the little preliminary troubles which appeared to have attended the introduction of these fine engines had been surmounted. I forwarded to you on Feb. 14th, and you were good enough to publish, the result of an experimental trip privately undertaken by myself, to test the accuracy of the allegations so persistently made that the 19in. engine could not keep time between St. Pancras and Leicester with trains of 12 coaches, but had to take a pilot with a train of that length, although the pilot herself could have drawn the train with ease in time. You will remember that the train (Scotch express) was taken by No. 1,675, the engine specially singled out and denounced as incapable, and that the load of 12 coaches was taken to Leicester, in spite of rain, a greasy rail, a fresh side wind, and an extra slowing at Market Harborough, in 3min. 5sec. under time—i.e., in 2h. 3min. 55sec. I gave the detail of the run.

Now that did not look like failure. Nor do the two following runs with the fast Nottingham expresses between Kentish Town and Kettering, both ways:—

| Miles from St. Pancras. | No. 1,668. 9 Coaches. | |

| Kentish Town (arr.) .......... | 5.57 |

The station times are given above to the nearest fraction of a second. All the times of passing mile-posts, &c., were carefully taken by me with an improved chronograph. It will be seen that the run from Kentish Town to Kettering, 70½ miles, occupied just 77 minutes, being slightly faster than that made by the celebrated Leeds expresses on the Great Northern in 1880. The average speed was 55 miles an hour, including starting and stopping. Some of the intermediate distances and times are very remarkable. The length of 58 miles from the 13th to the 71st mile post was covered in exactly one hour. This included the ascents of the long branches of 1 in 176 (passing St. Albans), and 1 in 120 to Sharnbrook Summit. The 17 miles from Leagrave to Bradford—slackening to 10 miles an hour through the latter station and yard—was done in 15¾ minutes, and the 16 miles from the 33rd to the 49th mile post in 13min. 50sec. Also, in descending banks of 1 in 120 and 1 in 200, a mile was several times run in slightly under 48 seconds, equivalent to speeds of a little over 75 miles an hour, the two fastest miles being done in 47·2 seconds each, or at the rate of about 76 miles an hour; this with a train weighing above 100 tons, exclusive of engine and tender. I do not think I can be wrong in characterising this as a remarkable and admirable performance. The "up" journey was a little slower, the average speed being 53, but with an extra coach and less favourable weather. I should mention that the down train was stopped by signal near Camden-road, therefore was 3½ minutes late in leaving Kentish Town; it reached Kettering half a minute early.

It may be said that the trains were comparatively light; but, even so, the speed over such a heavy road is quite exceptional. The allegation has been put forth that the 19in. engines were designed to run the Scotch expresses and to take twenty coaches up the Desborough bank without a pilot. That may be so, and some colour is given to the statement by the fact of Nos. 1,675 and 1,676 having been fitted with the Westinghouse brake for this purpose. Still, I cannot understand why, in that case, they should have been given boilers so much smaller than the other express engines; for it can hardly be contended that an engine is rendered stronger by decreasing her boiler power. If, however, on the other hand, these engines were designed specially for the lighter and faster Nottingham expresses—on which they have hitherto been almost exclusively employed—then it might be that the smaller boiler with larger cylinders is intended to secure more expansive working on those swift, light trains; to get, in fact, the advantages offered by the compound principle, as suggested some time ago by Mr. Stretton. Thus regarded, the engines would not be failures even if they could not run the slow, but far heavier, Scotch expresses. Nevertheless, I have shown already that they can keep time with twelve coaches, and even make up several minutes.

As I do not profess to champion these engines against others, but merely to record their actual work—having been specially enabled to observe it—I think it only right to add that while the down run with No. 1,668 is the best I registered, I have had several equal to that of No. 1,667, and some even quicker. For example, with No. 1,337, one of the 18in. cylinder 7ft. coupled (1,327 class), I have done the Kettering to Kentish Town journey in 78 minutes, and with No. 1,570, one of the 6ft. 9in. coupled (1,562 class), in 78½ minutes, as against 79 minutes with No. 1,667. But in those cases the trains were much lighter, being six coaches in the one case and seven in the other, while No. 1,667 had ten on; also, with the down train, No. 816, one of the 800 rebuilt class, took ten coaches from Kentish Town to Kettering in 79 minutes. I may add that No. 829 took a Scotch express of sixteen coaches from Leicester to Kentish Town (where it was stopped by signal) in 1h. 59min., notwithstanding that it was slackened by signal to 10 or 15 miles an hour at Market Harborough and Wellingborough, beside the usual slowing to 10 miles an hour through Bedford. These are all very fine specimens of express locomotive work.

**C. Rous-Marten, F.R.G.S.**

Wellington, New Zealand.

---

[24639.]—These engines, it seems to me, are undeservedly praised. Twice within the last three months, at the same place—i.e., Aldersgate-street Station, and at the same time, about 5 or 5.30 p.m., have these engines, which have been landed to the skies almost, broken down and blocked the traffic for the rest of the evening. Not having my memo. book by me at present I cannot give the exact dates, but most probably some readers of the "E. M." who travel into the City by the Great Northern and Midland railways must have been inconvenienced as well as myself.

I was rather surprised no account of either of these was given in our pages. The first I believe to have been caused by a broken crank axle (as usual). I should be glad, also, if some correspondent could inform me why the North London and Metropolitan trains are the only ones which do not start with a terrific jerk? The North London are especially prominent in this, as they often start quite imperceptibly, and glide smoothly off; while the Great Northern (at King's Cross, suburban especially) almost throw the unwary passenger across the carriage. I hope for a solution of this, which is a mystery at present to **Shylock.**

---

[24640.]—I observe with surprise the remarks contained in a letter in your last issue signed "Express," respecting the performances of the 1675 class of Midland engines. At all events, "Express's" disparagement of this class is in direct contradiction to the testimony of several Midland drivers with whom I have conversed on the subject, and all of whom speak in the highest possible terms of the work done by these engines. To a certain extent I can confirm what they say, having several times travelled in trains drawn by these engines lately. The run from Leicester to London is a very trying, long run, and in the words of Mr. Foxwell, in his very interesting little book entitled "Express Trains," "the average of 47 miles per hour attained over these steep ups and downs by the Scotch express, with its heavy train, is a first-rate performance."

Now, I travelled on the 3rd August last by the up day Scotch express from Leicester to London; the time taken was 119 minutes—an average of 50 miles per hour. The train was an unusually heavy one, and the engine was No. 1675, the very one alluded to so unfavourably by "Express" in his letter.

In the face of a fact like this it is difficult to believe that the performances of these engines can be so very unsatisfactory. I should be much obliged if Mr. Macmuir would favour us with a few particulars of the new 9ft. engine referred to in his reply in 57182.

**E. W. Sims.**

---

[24641.]—The professional earnings of Mr. Bob Sawyer at Bath could have been put in a wine-glass and covered with a strawberry leaf. The coal saved by the express compounds could, I believe, be stowed away in a receptacle of yet smaller dimensions. That the daily time sheets might rise up in judgment and condemn the compounds need not for one moment be doubted; but that the coal sheet would prove such a veritable *pièce de conviction* as the May sheet for the London engines, now recently issued, could never have been anticipated. The figures are as follows:—

| Number. | Name. | Coal per mile. lb. | Class. |
|---|---|---|---|
| 2184 | Reynard........ | 30· 2 | Precedent. |
| 477 | Caractacus...... | 31·50 | „ |
| 2191 | Snowdon ...... | 31·58 | „ |
| 871 | Proserpine...... | 33· 2 | „ |
| 1170 | General ........ | 33· 6 | „ |
| 872 | Wizard ........ | 33· 8 | „ |
| 366 | City of Chicago. | 35· 6 | Compound. |
| 310 | Sarmatian ...... | 39· 4 | „ |

These two compounds are the only ones stationed at the London end, and work in the same link as the Precedents quoted above. The bulk of the compounds are at Crewe; but I am told they work chiefly in a link by themselves, and therefore invidious comparisons are not suggested. From the official pamphlet descriptive of the L. and N.W. exhibits at the Exhibition we learn that the compounds were "expressly designed," *inter alia*, for "the greater economy in the consumption of fuel." Having regard to the figures quoted above, one would scarcely have thought it. Perhaps, though, the other compounds are not such gluttons as "Sarmatian."

Whether, in point of logic, one would be justified in inferring that the other (small) compounds, if worked in the same link as the London Precedents and under similar conditions, would give equally deplorable results, need not now be gone into. In coal, oil, &c., "Sarmatian" costs the company between three and four shillings per 100 miles more than "Reynard," and at the same time is equally inferior to the latter in speed power.

In justice to the big compounds, it is only fair to mention that they take, unaided, heavy trains, which otherwise might have to be divided, and thus save expense indirectly; but this is accounted for by their greater weight and higher steam pressure. A Precedent, under similar conditions, would do as much as a big compound with ease.

With reference to the letter of "Express" (24618), I am quite aware that Mid. 1675 has failed with the Scotch express. At first the slide bar was fixed too tightly, and on one or two other occasions the heating was attributable to experiments with a different kind of oil. Failures from such causes as these in no way affect my previous statement that these engines "are, or will be, amongst the finest in the kingdom." Their running is excellent; I have averaged nearly 54 miles an hour between Kettering and Kentish Town with the Leeds express, and 1675 has run the Scotchman from Leicester in two hours. Larger tenders are being built for them at Derby, and drivers will then be able to do the London-Leicester run even better than at present, without fear of scarcity of water. The coal consumption of 1667, 1668, and 1673 for the last three months averages 26lb. per mile. If engines which can run at such high speeds and with such a coal consumption, notwithstanding Midland gradients, are not amongst the finest in the kingdom I should like to know what are.

**Kappa.**

August 17.

### THE COMPOUND LOCOMOTIVES.

[24642.]—We have been lately hearing a good deal said about the faults of the L.N.W. compounds, stating their large coal consumption, and their inability to run down hill freely at high speeds. But I hardly think correspondents do these engines justice; they do not seem to consider the years it has taken to attain the present state of perfection. In the design of the ordinary two-cylinder engine there are numerous little details conducive to good working which can only be obtained by experience. Now in such a departure from the ordinary system as that made by Mr. Webb—there being hardly any previous practice in this direction to guide him —I think, taking all things into consideration, he has produced a wonderful engine. I also have reason to believe that the Dreadnought class are in every way an improvement on the older ones, being able to run down hill freely, and, moreover, having a moderate coal consumption. Now as to another point: I believe that the coal consumption on these engines depends a good deal on the drivers. For instance, only the other day I heard of one of these engines, whose name I could mention, in which the coal consumed was only 27lb. per mile, whereas another engine of the same class, I was told, consumed 30lb. per mile; both these engines were of the earlier type.

One more point and I close. I notice that all the correspondents talk about the L.N.W. compounds; none ever discuss the merits of the engines introduced by Mr. Worsdell on the Gt. Eastern Ry. Can any of our readers come forward and give us some information about these, as to what is their coal consumption, whether they run freely, are troubled with excessive back pressure, or what not? Any details of running would be very interesting, I am sure. **Adiabatic.**

### L. & N.W. COMPOUNDS.

[24643.]—I was informed a few days ago that two drivers, who had spoken their minds in answer to inquiries respecting the above, had each been put back to shunting at Crewe, thus proving the statement made by "Kappa" in "Ours" of the 31st ult. **W. H.**

[We trust our correspondent is mistaken. The heads of departments of a great company like the London and North-Western Company would, we hope, hardly try to stifle free discussion in this way. Such attempts would be as futile as they would be unworthy.—Ed.]

### TRAIN SPEEDS.

[24644.]—Noticing "D. A. P.'s" interesting letter (24582), respecting train speeds, I shall be glad if he will kindly inform me whether it is correct that a train leaves Grantham about 4.17 p.m., and reaches King's-cross in 118 minutes, which gives an average speed of over 53 miles per hour. This he does not seem to have noticed in his tables; but, if correct, must be the most remarkable run known. **C. R. K.**

### THE BINEGAR ACCIDENT.

[24645.]—On Friday, 1st inst., a fatal collision occurred at Binegar Station on the Somerset and Dorset Joint Railway. The line is single, with a loop or double line at the station, and consequently facing points. The points and signals were interlocked, but in order to make necessary alterations, the locking-gear had been taken out. The signalman by mistake pulled a wrong lever, and the approaching passenger train was turned into the loop-line, and came into collision with a goods train. An inquest has been held, and a verdict of Manslaughter returned against the signalman.

In reading carefully over the report of the proceedings, it will at once be noticed that most important information relating to regulations for working points when interlocking is out of order were not produced.

It will be remembered that after the Desford Junction accident, Major Marindin reported "that he had stated in a report upon a previous accident that whenever the interlocking affecting a facing-point connection is out of order, a man should be stationed actually at the points in order that he may keep the signalman informed of the position in which they are lying. He therefore urged the company to lose no time in issuing some regulations to insure the safe working of the traffic."

In pursuance of that recommendation, the Clearing House Committee of Superintendents drew up proper regulations, which came into force on the various lines October, November, and December, 1883, as mentioned (Vol. XXXVIII. p. 266).

The Rule 149A adopted by the company's parties to the Railway Clearing System says: "When the interlocking of any lever-frame, or any facing-point, bolt, or bar is out of order, or when any point or signal lever is defective, a competent man must be appointed to act under the instructions of the signalman. When there are facing-points, this extra hand-signalman must, before signalling a train forward, *inform the signalman the position of such points*, and satisfy himself that they are open for the proper line. There is no doubt that the signalman by mistake pulled over the wrong lever; but it will at once be seen that if the rule had been carried out, and a man appointed at the facing-points, the error would have instantly been detected.

Nothing can be more dangerous than to interfere with or take away the security of the interlocking system without appointing a man or other means to provide for safety. The signalman made the actual mistake, and for that he will take his trial at Taunton in November; but a much more serious error was made by the official who decided to remove the interlocking without carrying out the instructions contained in the rules, and, as it is now given in evidence, *without* the signalman knowing that the safety of the interlocking had been interfered with.

**Clement E. Stretton, C.E.,**

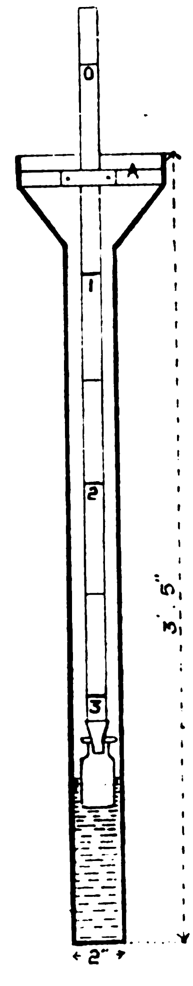
Saxe-Coburg-street, Leicester, August 17.

### AN EASILY-MADE RAIN GAUGE.

[24646.]—The following account of an easily-constructed rain gauge may interest some of your readers, who, like myself, are situated far out of reach of mathematical instrument makers.

The following sketch is a vertical section; the tube and funnel (or receiver) are of tin, the receiver being 6·4in. diameter, and the tube 2in. The float consists of a bottle carrying a very thin wooden index rod, graduated to inches and hundredths. The zero point is obtained by pouring water into the tube until the bottle just floats, and marking it on the scale on a level with the guide A.



The receiver being 6 4in. diameter, has an area of 32 17 superficial inches. A cubic inch of water weighs 0·578 ounce; therefore, 32·17in. will weigh 18·59 ounces, and that weight of water poured into the tube represents 1in. of rain on the ground. But to eliminate any inequalities that may exist in the diameter of the tube, I take only half this weight at once. Then each time this quantity of water is poured in, the index will rise above the guide A, an amount equal to ½in. of rain on the ground; the scale can be marked off accordingly, and subdivided into hundredths afterwards. I have obtained very satisfactory results from an instrument of this kind; it may be attached to a fence-post, or placed in any convenient situation out of reach of cattle or other animals.

**George Williams.**
Urbanna, Virginia, August 1.

### AERONAUTICS.

[24647.]—It is fortunate for Mr. Lancaster that he lives so far away as Chicago, as he thereby escapes some of the kicks that he would be in danger of receiving if he were in the neighbourhood of London.

The various kinds of flight observable in nature may be summarised as follows:—1st, the slow flight, requiring great power; 2nd, the more speedy flight, requiring less power; 3rd, the still more speedy flight of the albatross, requiring no power except that of steering, but depending on upward currents above the waves to receive forward impulses; and 4th, the perfect soaring flight, requiring neither wind nor power, but merely steering.

You say in your leader that "Mr. Lancaster has satisfied himself that the mathematics of the matter go to destruction in the solvent of common sense." Now I beg to differ *in toto* with this, and I say that it is entirely in accordance with my views of the laws of nature that a bird, or a man, with aëroplanes and steering apparatus, properly formed and steered, should soar all day long without the exertion of any power whatever, except that of steering.

If the flight is required to be made slowly, then great power is required, and the slower the speed the greater must be the power.

I have been very much amused at the Inventions Exhibition. Juryman No. 1 and Juryman No. 2 looked at my model boiler. I explained it to Juryman No. 1 in a few words, with the aid of my blue book, and I ventured to show No. 1 the modified form for aërial machines; No. 1 immediately went away as if he had been shot at, and No. 2 made a sneering remark and followed No. 1.

There is a little corner in the East Avenue of the Exhibition devoted to Aëronautics, and your readers will find there a very neat model made and exhibited by Mr. S. F. Pichler, in which the planes form the figure of 8 in a very ingenious manner. I was not there when the Jury came round, but I should have been glad of the opportunity, had it been possible, to observe the comedy. I say that Mr. Pichler's device deserved some kind of medal, but the intelligent Jury have thought otherwise.

I must not trouble you with the remarks of the public; they are more fit for the pages of *Punch*.

**Thomas Moy.**

### WHAT IS "CREATION"?—MYSTIFICATION—ALUMINIUM.

[24648.]—In letter 24590, page 518) "F.R A S." declines to accept "creation" simply as a sufficient explanation of observed facts—otherwise inexplicable—in the organic world, and deems it necessary to inquire further, "What is the cause or operative agent in creation?" For the scope and purposes of the scientist, I consider this is quite as unnecessary as to inquire, What is the cause or operative agent in gravitation?

"F.R.A S.," however, seems conveniently to have overlooked the alternative which, in anticipation of his non-acceptance of "creation," I offered to him (letter 24552, page 477), "Why, as a true scientist, should he hesitate to declare the insufficiency of natural selection *per se* to account for organic nature as we find it?"

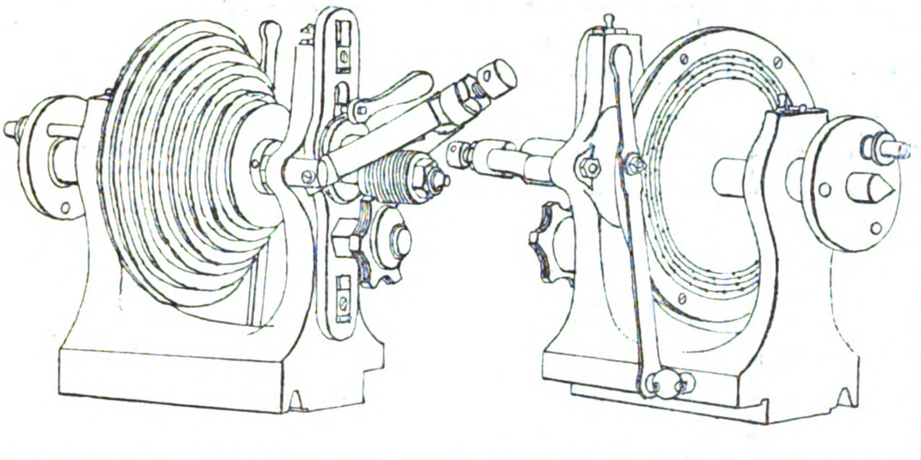
"Rho," in letter 24589, page 502, enters a protest against the "inordinate use of abstruse formulæ."

I sympathise with him so far, and am aware that many lecturers inflict on popular audiences terms and formulæ that are far beyond the comprehension of more than one or two of their hearers. While, however, deprecating such unnecessary pedantry, it will be evident to "Rho" that lecturers must be explicit, and, to avoid misapprehension, must have recourse to technical terms or formulæ. He himself affords an example of the necessity of this when he states that he would prefer the term "*cuprous* sulphate" to the symbol, "$CuSO_4$," which is not *cuprous*, but "*cupric* sulphate."

Before now the price of metals, notably that of copper, has been depreciated by reports of the discovery of new and economical methods of preparing aluminium, but in no instance have these reports been substantiated. The direction in which practical men look most hopefully for economy is in the production of cheaper sodium. Thus, in the process proposed by the late S. Gilchrist Thomas, the reduction of carbonate of soda is effected in cast-iron tubes or casings, with a thick internal lining of dolomite or magnesia. These are heated internally by reducing gases, which have been previously superheated by being made to pass through a small regenerator. **H. B. F.**

### GERMAN LATHE WITH TRAVERSING MANDREL.

[24649.]—Our lathemen seem to be taking their summer holiday; but I hope to revive the subject by sending you the inclosed photograph, for which I hope you will find space. The French form of traversing mandrel is well known to us in England, and has been several times illustrated and described



in these columns. The London pattern is also known. Here, however, we have something which will, I suspect, prove new to most of us. In this form the guide which steadies the mandrel and prevents it from traversing is semicircular; and it is fixed to a slotted plate attached to the back of the headstock in such a way that it can be moved up and down a short distance by means of the handle seen projecting to the right in Fig. 1. Attached to the same frame is seen the fixed guide, with its six threads. This is the same as in the London pattern, except that it requires no eccentric to raise and lower it. Having chosen the required thread, fixed the screw-guide on the end of the mandrel, and turned the corresponding thread to the top of segment nut, all that is required to set the mandrel traversing is to throw over the handle; this releases the mandrel by raising the semicircular stop-guide, and, at the same time, raises the guide-nut into contact with the guide-screw.

The mandrel is bored up; but is stopped at the end by the pin, which takes against the tail-pin. The fork which holds the tail-pin is hinged, to enable the ferrule guides to be changed.

These are the lathes introduced to us by Mr. Wenham, for which I think we owe him our best thanks. They are to be advertised in the "E.M." by the London agent of Mr. Walz. The workmanship and design pleased me very much, and a very curious and novel arrangement is used for trueing the screw-guides when in position, which I hope to introduce to your readers.

The only objection I can see to the arrangement is the difficulty of fixing or applying the spiral chuck to the tail end of the mandrel. I have been trying to contrive a plan of meeting this difficulty.

**F. A. M.**

## LATHEWORK AND OPTICAL INSTRUMENTS.

[24650.]—Myself, and many amateurs who possess lathes, are anxious to be able to fit up various optical apparatus and instruments, say, telescope, microscope, and the various accessories connected therewith, and we shall be extremely thankful if some one of your numerous contributors will give a short series of articles explaining the lathework and tools used in connection with the construction of these instruments, as the mechanical work connected with one equally applies to the rest. I hope some one versed in this line will intimate his readiness to help us.

August 17. **An Amateur.**

## GRINDING TOOLS FOR HAYDON'S CUTTER-BAR.

[24651.]—In answer to "J. D.'s" letter, No. 24574, if he will look at Fig. 3, page 433, he will find a thick-dotted line marked O°. This is the horizontal diameter of the grindstone, and the line he mentions, marked 2½°, joins it at that angle. All he has to do is to set this out with a protractor, or get the angle in any other way. This will give the height for grinding a tool that has a plan angle of 80°, if cutting edges of 60° are wanted—that is, if the tool is wanted for iron; but if you want a cutting edge of 80°, the same tool must be ground at the line marked "brass 80." But, bear in mind, the figures on the grinding gauge refer to the plan angle of the tool, and not to the cutting edge produced. All the heights marked "iron" for tools, with plan angles of 80, 90, 100, and 120, give the same cutting edges of 60°, although ground at different heights; but the tool must be held in one of Haydon's cutter-bars, properly made—that is, pitched at an angle of 55°. These remarks refer to all the other radiating lines. The horizontal lines are ruled parallel with the thick-dotted one, and are only for the purpose of conveniently marking the grinding gauge. The "×" "J. D." cannot find does not refer to a letter, but to a cross on the left side of A, Fig. 3. This explanation will perhaps make all clear. About advancing the tool as it has just been set for height, of course it must be horizontally, or the setting would be lost. By reversing the tool in the holder, it is meant that it should be turned half round for the purpose of grinding the top face.

The grinding angles are all from the tables left us by Prof. Willis. I have only adopted them to the pitch of Haydon's cutter-bar, and I do not know enough of trigonometry to explain the principle.

I trust "J. D." will not give up at the difficulties to be found just at the first. They soon vanish, and his reward will be a tool that always turns off long, bright shavings; one made in a short time for any kind of metal; and one you know must be right, needing no water, except for the last cut, when it leaves a surface like silver, one that should be touched by neither file or sandpaper. I should be glad to draw a grinding gauge on paper for "J. D.," if he likes to advertise his address; or examine his holder if he has any doubts as to its being correctly made, or I would let him know the maker of mine.

**A. Atkinson.**

## POWERS USED ON CERTAIN TELESCOPES.

[24652.]—I had intended referring to Mr. Sadler's interesting letter (24532, p. 456) before this, but want of leisure has hitherto prevented my doing so. It struck me at the time of reading, however, that the statements there made of the powers used by Struve and Burnham, the two observers who, of all others, have contributed the greatest quota of double star discoveries, were calculated to produce somewhat erroneous impressions. During an hour or two of leisure, I set myself the task of wading through the first half of Struve's "Mensuræ Micrometricæ" (as represented by Lord Lindsay's "Summary"), and the analysis made may perhaps interest Mr. Sadler and others. The first column gives the nominal powers; the second the corresponding actual powers, as measured by Σ.; and the third the number of double stars examined with each. The Dorpat achromatic had an aperture of $9\frac{6}{10}$in., and its focal length was about 14ft.

| Nominal powers. | Actual powers. | No. of stars. |
|---|---|---|
| 140 | 133 | 2 |
| 140-214 | 133-198 | 1 |
| 214 | 198 | 7 |
| 214-320 | 198-254 | 5 |
| 320 | 254 | 683 |
| 320-380 | 254-? | 33 |
| 320-480 | 254-420 | 416 |
| 320-600 | 254-532 | 38 |
| *380 | ? | 2 |
| 480 | 420 | 99 |
| 480-540 | 420-? | 3 |
| *540 | ? | 1 |
| 480-600 | 420-532 | 86 |
| 480-800 | 420-682 | 4 |
| 480-1000 | 420-848 | 1 |
| 600 | 532 | 13 |
| 600-800 | 532-682 | 5 |
| 600-1000 | 532-848 | 1 |
| | | 1400 |

The powers marked * are not mentioned in the introduction. Thinking it possible that 380 was a misprint for 480, I referred to the "Mens. Microm." itself, but found that it was copied quite correctly. And 540 might be intended for the 532; but this is merely a suggestion. It will be seen by inspection of the above table how much, or, rather, how little, was done with 100 to the inch of aperture. Nearly 50 per cent. (683) of the objects were measured with a power of 254—26·5 to the inch! And no less than 449 others, with powers of 254 to 420, the maximum being 44 to the inch. Power 682 was only used on nine objects, and 848 on two only, out of a total of 1,400. If even 90 to the inch is only used on *one* object in 700, we may well leave still higher powers to the time when, as quaint old Kitchener says, "the atmosphere be removed, and the earth stands still."

And now for the Chicago refractor. Mr. Sadler says:—"Most of the close pairs were measured by Mr. Burnham with the highest power, 925." In this month's *Observatory* there is an article on "Large *v.* Small Telescopes," by Prof. G. W. Hough, where I read as follows:—

"In the climate of the United States the nights on which the highest powers may be used are rare. I presume *three-fourths* of all the observations by Mr. Burnham and myself, with the Chicago refractor (18½in. aperture), were made with a magnifying power of 300, and the balance with higher powers up to 925." The italics are mine. In other words, 75 per cent. of the objects were examined with a power of 16·2 to the inch of aperture. Moreover, the highest power here indicated is just 50 to the inch. And I think no one can say that either of the two fine telescopes (at Dorpat and Chicago) are imperfect specimens of the optical art.

**W. S. Franks.**

## SAFETY BICYCLES.

[24653.]—As an old rider who has tried nearly every form of bicycle and tricycle, I may answer your correspondent (letter 24609, p. 520). The geared machines with small drivers are, in my own experience, most unsatisfactory, unless the machine *exactly* fits the rider. I have tried them, and found very slight differences in machines by the same maker produce a most extraordinary difference both in comfort and speed, and I have no doubt whatever that if your correspondent will try several machines until he finds one which exactly suits him, he will settle down to this with the most perfect satisfaction. I am 6ft. high, 46 years old, and weigh 200lb., and with a 40in. Safety geared to 56in. I can hold my own with most without effort, and can pass most riders on 50in. to 54in. ordinary bicycles. The presence or absence of jolting depends entirely on the length and proper strength of the seat spring. I can ride up any hill which I could surmount on any bicycle or tricycle I ever tried, and I leave the dust behind. The fault is not in the system, but in your correspondent's machine. My own has ball bearings throughout, a very long and elastic seat spring, and one of the best suspension saddles, and for the first time in fifteen years I may say I am perfectly satisfied, and can ride on ordinary roads as fast as I care and dare to do.

Your correspondent had better make a change, and not buy another before he has tried it thoroughly, and is perfectly satisfied both as to speed and comfort.

**T. F.**

[24654.]—In answer to letter (No. 24609) from "?" with reference to the Safety bicycles, I beg to send my experience; and as I have tried most machines, bone-shakers, bicycles, tricycles, &c., it may be of use to "?." By his letter, it is evident that he is not satisfied with a Safety; but I can't say that I agree with him. He says that there is a great strain on the wrists, and that the steering is hard. Here I in a measure agree with him. These machines are certainly more difficult to steer than an ordinary bicycle, though you after a time get used to them. He next states that he can't get up a speed above nine miles an hour. I cannot understand this, for whatever faults can be found with the unfortunate Safeties, loss of speed is not one of them. I have no difficulty in riding fourteen or fifteen miles an hour, and recently rode forty-five miles in three and a half hours. No rider on any kind of machine would, if he valued his tires, ride through newly-laid stones; but there is generally a path at the side which does for a bicycle, although useless for a tricycle. I have always found it *impossible* to go over the handles, except once, when a drunken drover caught my small wheel and lifted it up (the wheel caught him in the face and knocked him down). The vibration caused by the small wheel is considerable, especially in those machines in which the small wheel leads, but this is much reduced by a "cradle" spring and thick tires. I have never found the dust on the clothes worse than on a tricycle, although it is greater than on a bicycle, but it collects on the lower cog-wheel and chain. You say that you cannot ride hills which you could on a tricycle, and that your machine is hard to drive. The machine which I am now riding, and to which all the above refers, is a "Rudge" pattern, 40in. wheels geared to about 63in., with ⅞in. tires. With this, although geared much higher than yours, I can ride almost any hill much easier than on a tricycle (the one I have at present is a "Humber," geared to 54in., and this, in my opinion, is far the best type of tricycle, except for very rough roads, when two-track machines are most useful). I had a "Facile" for a short time, but did not care much for it. It is certainly very easy to drive, and the best hill-climber of any machine which I have tried, and also is quite safe; but to go at any speed you have to treadle very fast, and the motion is very jerky. I have not tried the "Xtra" (Singer's), but although its appearance is against it, several friends of mine speak very much in its favour. I have now and then borrowed a Safety with the small wheel in the front. On these it is quite impossible to take a header, as you are nearly half-way between the wheels. I can't say much either way about them from experience, as I have not ridden 50 miles altogether; but from what I hear, the "Rover" (Starley and Sutton) is one of the best.

To sum up, I think that a Safety is superior to a tricycle for speed, and hill climbing, and ease of driving, and that they are quite as fast as an ordinary bicycle, although not so easy to steer or drive; also that the vibration is greater than on either a bicycle or tricycle (except old rear-steerers). A well-made Safety is safer than either a bicycle or a tricycle, especially at night. I would not recommend one geared as high as mine, for, although I manage it all right, I have ridden for many years, and many who have tried my machine say it is geared too high for much hill work.

I must apologise for the length of this letter; but it has taken up much more space than I expected when I commenced. **C. A. W.**

## WATCHMAKERS' QUERIES.

[24655.]—I NOTICED in your paper about a fortnight ago a query with regard to the fitting of balance springs, signed "Caribbean." This week I find the query answered in two different ways. The first letter is by "Escapement" (57159), who answers the requirement satisfactory to me. His method of selecting a balance spring is that which I always have been accustomed to do—that is, if a watch requires a fresh balance spring I put one in that will stretch a trifle further out when the balance is suspended from the spring.

The next letter is by "Peganredstuff" (No. 57159), and he commences by saying the number of beats per hour must first be ascertained—say (says he), for instance, it is 16,200; that would be nine beats or vibrations of balance in two seconds. I should like to know how the number of beats can be ascertained in the first place. A watch may come to be repaired, and it, with the old spring in, may go at the rate of 20,200, and, if so, of what use is the old spring? It appears to me to be of no use in this case by "Peganredstuff's" way of reckoning. He further says, with regard to the testing of a balance spring: "Lay it on balance arms, verge upwards, and gently press collet down on it sufficient to hold spring." We are agreeable so far. Then he says: "Take hold of spring so many turns from outside coil as is right size." How can he tell that it is right size when the old spring is wrong altogether? What has he to go by? I should like "Peganredstuff" to say. Further, he says, hold it with the tweezers; "with a touch set it vibrating and count." Does he mean to say he is to count every action of that balance until it stops, then calculate the number he has counted and the time it has taken him? He then finishes by saying you can try any number of springs, and I believe him, for you may try many an hour before you are satisfied, and when you have got it in the watch you may be wrong after all.

"Escapement's" method is far the wiser, so far as I can see. I should like a reply.

**J. Brierley Delph.**

## COMPARISON OF TIDES.

[24656.]—THE tides during the month of July have been more in accordance with the predictions than they have been for several months past, and the fact that the law of the "diurnal inequality" has been correctly formulated has, in consequence, received ample verification. We simply challenge competition with any other tables extant, when placed side by side with the Admiralty Tables for Liverpool. The promoters of the method, of calculation, based on the Harmonic Analysis of the Tides, have been appealed to again and again to produce a sheet of predictions for any month, for the purpose of being compared with those given by Sir John Lubbock's method, revised and extended; but, with a haughtiness peculiar to themselves, which, however, indicates weakness, they simply decline, confining themselves to the Indian ports, for which the promoters are subsidised. A reference to the "Daily Meteorological Reports" points out when anticyclonic conditions have prevailed, and at those times the sea-level is depressed. This has been the case during the latter days of July, and hence the largest discordances have then become apparent. But it is noticeable how, even under these circumstances, the "diurnal inequality" asserts itself. For example: on the 29th, 30th, and 31st the tides are gradually diminishing in height, but the night-tides maintain their superiority, and each is higher by a foot than the preceding day tide, the summits of the tidal curves forming a zig-zag line which used to be excessively puzzling to early investigators, and even more so to early observers. The irregularity demanded explanation, and an explanation has been offered, which either is, or is not, the correct one. No one as yet has ventured to assail, or even to criticise, the explanation which I have offered in the method of computation offered by the Admiralty. What is to be inferred from this circumstance I must leave to others to judge.

**James Pearson, M.A., F.R.A.S.**

Fleetwood Vicarage, Aug. 6.

COMPARISON OF TIDES AT LIVERPOOL AND FLEETWOOD IN JULY, 1885.

| Date. | Calculation. | | Observation. | | Error. | Barometer | Wind. | Remarks. |

## THE HISTORY OF THE TIDAL PROBLEM.—III.

[24657.]—THE harmonic analysis of the tides, which was introduced by Sir William Thomson, and was carried out into figures by Mr. E. Roberts, and which now is elaborated by means of a tide-predicting machine, produced by them jointly, demands only a few observations, and for this reason, that the reports of the British Association dwell upon this method exclusively, and appear to take it for granted that "any modification of what is called the *equilibrium theory*, which shall extend its details, and bring it into nearer agreement with the facts of observation, is simply impossible." In fact, Sir William Thomson has caused it to be set down in writing as his ultimate decision, "that he did not think it would be advisable to print any tables regarding this subject which are founded on any method less complete than that of the harmonic analysis employed by the British Association's Tidal Committee." We can, therefore hardly expect any fresh prizes to be offered for the best and most approved treatises on the subject under that sanction.

The principle of the method to which we are now alluding may be regarded as an extension of that introduced by Laplace. What is called a harmonic function is an expression of the form $R \cos. (nt-\epsilon)$, and the successive values it assumes throughout its cycle of changes may be shown by a very simple contrivance. Suppose two wheels of the same diameter (like the driving-wheels of a locomotive engine), with cranks attached to the centre of each, of equal length, and parallel to each other, the extremities of these cranks being held together by means of a connecting rod. Then, as is seen in the motion of a locomotive thus constructed, when the wheels turn round, the connecting rod will remain horizontal, but it will rise and fall *above* and *below* the line joining their centres once in each revolution; and its height *above* or depression *below* this line will be exactly $R \cos. nt$, where $R$ is the length of each crank and $n$ the angular velocity of rotation of the wheel—i.e., the angle through which each turns in a unit of time. The rise and fall of this connecting rod, then, will represent the rise and fall of the sea during a tide, so far as that rise and fall depend on *any one* of the causes, which are many in number, by the sum-total of which the whole tide is generated. I will add nothing more in reference to this theory, except to assert that although correct in principle, when certain modifications due to the actual operations of nature are kept out of sight, it fails under the actual conditions of the problem to serve as a basis for the accurate predictions required in tide-tables.

The next and last attempt at a solution of the tidal problem to which I have to refer, is based on Sir John Lubbock's method; but is a revision and extension of that method. The difficulty which has beset every attempt to form tide tables which should serve the purposes of prediction, and be a sure guide to harbour masters and others employed in the docking of ships, has arisen from what is called the "diurnal inequality" of the tides, by the operation of which it comes to pass, that when the tides are springing, for instance, their heights do not succeed each other by regular steps of elevation, but follow each other in a zig-zag fashion, the night tides being at one season higher than the day tides, and *vice versâ* at another. Now, what is claimed is, that a complete explanation has been discovered, both of the cause and effect of this "diurnal inequality" for the first time by this method, the proof being that tide tables, computed on the principles of this explanation, give results in exact accordance with observation. A refutation of this statement has been publicly challenged, but has never yet been successfully made, and the Admiralty tide tables for Liverpool having for ten years past been constructed by means of tables based on this method, are allowed to be put in competition with any others by whomsoever devised, and their correctness has never yet been called in question. It may be that the method is considered undeserving of criticism, because not brought out under the ægis of names renowned in the scientific world; but all this display of haughtiness does not affect the fact of the superiority and truthfulness of its principles. The law of this "diurnal inequality" has been so often enunciated that it is unnecessary to repeat it, and, although the regulations of the Royal Astronomical Society forbid any discussion of the method in the pages of its *Monthly Notices*, forsooth "because a similar communication has been made in the English Mechanic," yet "Magna est veritas, et prevalebit."

**James Pearson, M.A., F.R.A.S.**

Fleetwood Vicarage, July 30.

## GERMAN GUNNERY.

[24658.]—The high foot-second velocity reached by Herr Krupp's guns is a fact patent to all Europe. To ascertain the resistance of the air to the motion of shot at all practical velocities, is a problem that, up to a recent date, has baffled all experimenters, from Sir Isaac Newton downwards. Did the resistance of the air vary as the square or cube of the velocity, that is to say, was the resistance increased to four or eight times for doubling velocity?

To this task an Englishman, Professor Bashforth, devoted the cream of his life. Formerly a second wrangler in that splendid year when "Neptune" Adams was senior, Bashforth, seizing the extraordinary experimental difficulties of the problem, with his own hands constructed a delicate chronograph, which we have minutely examined, capable of recording the hundred-thousandth part of a time-second. Erecting 10 screens of thread-work, he superintended the discharge of 500 rounds of cannon shot, each of which, by electric action, recorded the precise instant of its passage through each screen, and at the same time a clock, beating half-seconds, dotted down the seconds of time. Microscopic examination of these electrical records published the exact epochs and diminishing velocities of the flying balls. As we have had the advantage of witnessing the calculations by which from these data the history of the flight of the ball is determined, we are prepared to appreciate the enormous labour undertaken, spontaneously by Prof. Bashforth when tutor to the advanced artillery class at Woolwich. It is, therefore, utterly improbable that Herr Krupp (whose mathematical acquirements are at least unknown) has calculated a set of tables of mètre-second velocities of cannon balls. But when we come to examine these German tables we find (with slight alterations) they are the identical tables evolved by such huge labour by Mr. Bashforth. We need not wonder, then, that he feels aggrieved, and justly distributes the following *protest*:—

"A Protest.

"'Reports on Experiments made with the Bashforth Chronograph to Determine the Resistance of the Air to the Motion of Projectiles 1865-1870,' (84/B/1941), were published in 1870, and the final report on experiments 1878–1880 (84/B/2909), in 1880, which contained coefficients of resistance for ogival-headed shot for velocities between 100 and 2,800ft. per second, or, between 30 and 853 mètres per second, and two general tables connecting velocity (1) with time, and (2) with space.

"In the following year M. Krupp published 'Table de Krupp pour le calcul des Vitesses restantes horizontales et des durées de Trajet des Projectiles oblongs. Essen, 1881.'

"These tables of M. Krupp are the same in substance as my general tables, substituting French for English measures. They differ only in supposing a slightly reduced resistance of the air due to a more acutely pointed shot, &c., to the extent shown in the accompanying diagram,[*] or, in a similar diagram given by Professor Greenhill in the *Proceedings* of the R.A. Institution, Aug., 1884, p. 60. M. Krupp makes no reference to the results obtained by any prior experimenter.

"I desire to direct particular attention to the fact that an intermediate report of mine, dated July 8, 1879, was printed and circulated in 1879 (84/B/2853), of which I received 100 copies. That report gave coefficients extending from velocity 430 to 2,250ft. per second, or from velocity 131 to 685 mètres per second, while M. Krupp's tables extend from velocity 140 to 700 mètres per second.

"Having devoted much time and labour (1864–1880) in carrying out ballistic experiments at Woolwich and Shoeburyness, I object to have results very similar to mine laid before the public as perfectly independent discoveries. I have no claim to make to anything beyond what was contained in my reports to Government, and published before the experiments of M. Krupp are said to have been made.

"F. Bashforth,
"Late Professor of Applied Mathematics to the Advanced Class of Royal Artillery Officers, Woolwich.

"Minting Vicarage, Horncastle, Dec., 1884."

And in another statement of the case we read:—

"Bashforth's general tables connecting space, time, and velocity of spherical and ogival-headed shot were derived from the results of more than 500 rounds of 3, 5, 7, and 9in. shot fired at Shoeburyness in 1867, 1868, 1878, 1879, and 1880. The satisfactory performance of these experiments involved the invention of a new chronograph specially adapted to the work to be done. . . Krupp's tables made their appearance at Essen in 1881. And it is stated that they have been "établi par l'usine Krupp au commencement de l'année 1880" (p. 18). But no details of the experiments have been furnished. No information has been given respecting the instruments used in making the experiments. No reference is made to any prior experimenter. The two tables of Krupp 1881 are precisely the same as those of Bashforth 1871, &c., except only that French replace English measures, and that a small reduction is made in the resistance of the air, which is such as might be expected from slightly improved steadiness, and a more acutely pointed form of shot. Krupp's attention has already been called to this matter in *Nature*, No. 753, April 3, 1884, p. 528. Krupp's publication is valuable as (1) confirming Bashforth's previously published results, and (2) showing the strictly practical nature of Bashforth's work originally undertaken in connection with the advanced class of Royal Artillery Officers, Woolwich."

Now that the results of Bashforth's experiments have come into general use in R.A. and Navy text-books, the late Government, through Lord Hartington, awarded him £2,000 in recognition of the value of his labours, which have been extended over 20 years.

The mathematical investigations are of the very highest order of research. The results are throughout tested by the principles of interpolation and second and third differences—principles capable of detecting the slightest errors of observation or calculation.

**G. W. Royston-Pigott.**

## LEGAL REPLIES.

[24659.] — Will — Dower — Freeholds (57051).—The clause quoted by the querist from the purchase deed has nothing to do with his will. It is a clause commonly inserted in conveyances to "bar dower," as the phrase is: that is, to prevent dower from attaching in the event of the purchaser dying intestate, when the widow would, in the absence of this clause, as dower, be entitled to one-third of the property; but when a will is made, as in this case, that overrides everything, and, as the querist here has made his will in his wife's favour, giving her all his property, both real and personal, this freehold would pass to her if it is in his possession at his death, while its having been bought since the date of the will is altogether immaterial.

Income Tax — Partnership — Returns — Exemption (57189). — The answer to this question by "Os" is so amazing, and may be so misleading, that I feel obliged to correct it fully. He writes: "The tax is levied upon individuals, not partnerships or firms. Let each partner send in a separate return, and no mistake can be made." This is entirely erroneous. By the Income Tax Act, 1842 (5 and 6 Vict., c. 35, s. 100), it is expressly provided that where a trade or profession is carried on by two or more persons jointly, *the return must be made and stated jointly*, and the duty is computed in one sum and separately from any other duty chargeable upon the same persons, or either or any of them. That clause is plain enough, and it is always acted upon. The only case in which a partner may make a separate return of his trading profits is where he seeks to claim exemption. If in this business each partner does really only earn an income below £150, he must make a separate return and declaration to that effect, and for this purpose he had better apply to his collector for the proper forms. But the law is as plain as possible, that except when claiming exemption no partner can make a separate return; but the return must be made and stated jointly. The Income Tax Acts are very hard reading, and very confusing. For this reason I have much pleasure in recommending a little book just published by Stevens and Sons, Chancery-lane, at 7s. 6d., and called "A Guide to the Income Tax Acts, for the Use of the English Income Tax Payer," by Mr. Ellis, solicitor, which I have found handy as a help through the bewildering mazes of the Statutes themselves.

Land—Contract — Completion (57206). — As money was paid on account, there seems to be a clear contract for the sale, if not, indeed, an actual sale, of this land. The querist can therefore compel the vendor to complete and give him a title by an action for specific performance in the Chancery Division, or he can let his bargain go and sue for his money back again, with damages for breach of contract, the amount of which will partly depend upon the rise or fall in the value of the land. As to the size of the house, this is often regulated by restrictive covenants, in order that neighbouring property may not be depreciated. If there was any agreement that such a covenant should be inserted in the purchase deed, then the querist would be bound thereby, but not otherwise.

**Fred. Wetherfield, Solicitor.**

2, Gresham-buildings, Guildhall, London.

## ORGAN DESIGNING.

[24660.]—If you will allow me, Mr. Editor, I should like to supplement my remarks on the above, which appeared on July 31, by an illustration, consisting of a specification of the chief, or great manual, of a first-class instrument. Compass, CC—$C^3$, 61 notes.

|---|---|---|
| 1. | Double open metal, 16ft. and 8ft. | 122 pipes. |
| 2. | Double stopt wood, 16ft. and 8ft. | 122 ,, |
| 3. | Large open metal..........8ft. | 61 ,, |
| 4. | Small open metal..........8ft. | 61 ,, |
| 5. | Stopt wood, or gamba......8ft. | 61 ,, |
| 6. | Octave open metal ........4ft. | 61 ,, |
| 7. | Stopt wood................4ft. | 61 ,, |
| 8. | Mixture, 8th, 12th, 15th ...... | 183 ,, |
| 9. | Furniture, 15th, 17th, 19th, 22nd, 26th, 29th ................ | 366 ,, |
| 10. | Harmonic mixture, beginning at 8ft., containing 8ft., 5⅓ft., 4ft., and the whole harmonic series including the 7ths, XIV. ranks .............. | 854 ,, |
| 11, 12, and 13. | Double trumpet, trumpet and clarion of 16ft., 8ft., and 4ft. | |

The above contains three stops of 16ft., seven of 8ft., five of 4ft., three of 2ft., one of 5⅓ft., two of 2⅔ft., besides fourteen ranks of chorus, making up what in a modern organ would amount to twenty-four stops.

It will be seen that the stops are not given useless and ornamental names, such as "clarabella," "Höhl Flöte," and so on, but are described as what they actually are; the scale, material, and pitch alone being written on the stop handle. The specification contains, it will be seen, 13 stops instead of 24, the number of pipes being 2,135.

The performer finds the same variety as if every rank of pipes had its separate stop knob. No organist ever uses the doubles without the corresponding unisons. The fifteenth is never used by itself, nor the twelfth, and neither of them without the principal; so that in obeying the direction, "full to fifteenth," only one knob has to be drawn (No. 8) instead of three.

I might have put the three reeds under the control of one handle, for in such an instrument they would always be drawn together, as the solo reeds would be found elsewhere; but that would be too much of a shock to old-established prejudices.

I now append the corresponding pedal:—

| | | |
|---|---|---|
| 1. | Double open metal, | 32ft. and 16ft. |
| 2. | Bourdon ........ | 32ft. and 16ft., or 16ft., 10⅔ft., 8ft. |
| 3. | Open metal...... | 16ft. |
| 4. | Open wood ...... | 16ft. |
| 5. | Violone.......... | 16ft. |
| 6. | Octave metal .... | 8ft. |
| 7. | Octave wood .... | 8ft. |
| 8. | Mixture ......... | 8ft., 5⅓ft., 4ft. |
| 9. | Sesquialtra....... | 4ft., 2⅔ft., 2ft. |
| 10. | Contra Bombarde | 32ft. |
| 11. | Heavy Reed ..... | 16ft. |
| 12. | Light Reed ...... | 16ft. |
| 13. | Octave Reed..... | 8ft. |

Here in 13 stops we find the same contents as comprised in a pedal of 18—namely, two of 32ft., seven of 16ft., four of 8ft., two of 4ft., one each 10⅔ft., 5⅓ft., and 2⅔ft.

No. 8 might also contain 10th, 6⅖ft., as it would never be drawn except with nearly a full pedal.

**John T. Lawrence, B.A.**

[*] The diagram is too large to reproduce satisfactorily.

## EXAMINATION OF MINERALS BEFORE THE BLOWPIPE.—IV.

[24661.]—Box No. 16.—White, opaque, amorphous, glittering, cryst. struct. (like loaf sugar); hardish (penknife makes little powder, but leaves no steel on surface); crushes easily.

| | |
|---|---|
| I. Powder in B acid. (1) Great effervescence for a short time only (*a*) yellowing the green p.c. (2) Transparent colourless balls, rapidly fusing into one large one, not quite round, (*b*) opaque hot; and evolving only a little opaline matter under treatment. | (1) Carbon dioxide.<br>(2) Probably a combination, or rather conjunction, of calcium and barium. |
| II. Fragment of mineral at point of pyrocone. (1) Yellow-green p.c. (2) Red orange p.c. in E P. (*c*) (3) Fragment turns green where heated. | (1) Barium. (2) Calcium. (3) Barium manganate (according to Plattner), but no proof of manganese here. |

There can be no doubt about this mineral.

Box No. 17.—White, semitransparent, amorphous, fibro-cryst. structure; soft, or very soft, crushes easily.

| | |
|---|---|
| I. Powder in B acid. (1) Red p.c. at bottom of bead. (2) Great effervescence, green p.c. unchanged. (3) Transp. fragments after long treatment, but one or two minute opaque balls. | (1) Lithium or strontium. (2) Sulphuric anhydride(*d*). (3) Cannot be aluminium silicate containing lithia or strontia, because the mineral is soft. |
| II. Fragment in E.P. (1) Orange red p.c. | (1) Strontium. |
| III. Added CoO. (1) No solution of cobalt borate. | (1) No alkali (no lithia). |
| IV. Powder fused with $K_2O$ (*e*) on Al plate, boiled, dried, and treated in B acid. (1) The whole transparent balls (2) A little grey opalescent matter. | (1) Strontium (the red p.c. showing it cannot be lime).<br>(2) A little combined water. |

What mineral is this? (*f*)

Box No. 18.—Nearly opaque, white, amorphous, hardish; little powder, but no steel left.

| | |
|---|---|
| I. Powder in B acid. (2) Momentary rose p.c. from bottom of bead. (2) Great but brief effervescence, with temporary yellowing of green p.c. (3) Transparent balls, larger ones not quite round. | (1) Strontium or lithium. (2) Carbon dioxide. (3) Strontium, the borate of which must have a higher sp. gr. than that of calcium. |
| II. Fragment in E.P. (1) Beautiful orange-red mantle completely enveloping the blue pyrocone. | (1) Strontium. |

What mineral is this?

Box No. 19.—Pale-green (some fragments violet) transparent, amorphous, but with apparently a cubic angle on one side—hardish.

| | |
|---|---|
| I. Powder in B acid. (1) Slight red-orange p.c. from bottom. (2) Great effervescence, with slight choking smell. (3) Transparent balls, larger ones quite round, giving off no opalescent matter under continued treatment. | (1) Probably lime. (2) Chlorine or fluorine. (3) Lime; not baryta or strontia. |
| II. On copper wire with B acid. (1) No blue p.c. | (1) No chlorine. |
| III. Bead with fresh powder boiled in glass bulb with drop of water. (1) Neck attacked. | (1) Fluorine. |

What mineral is this?

Box No. 20. Transparent, lamelar, amorphous, but cleaves in plates: soft.

| | |
|---|---|
| I. Powder in B acid. (1) Great and long-continued effervescence, green p.c.; unchanged; no smell. (2) Transparent balls, larger ones quite round. (3) Clear, hot. (4) Balls colourless when cold. | (1) Sulphuric acid (confirm according to note (*b*) "E. M.," p. 390. (2) Lime. (3) No magnesia. (4) No iron. |

What mineral is this?

Box No. 21.—Pale (apple) green, translucent, compact, amorphous; soft (penknife leaves considerable powder on surface).

| | |
|---|---|
| I. Powder in B acid. (1) Considerable, slow (not lively) effervescence, increasing with increased heat. (2) Only white opaque fragments after long treatment, but evolving streaks of opalescent matter, which render the whole bead opaline after a time. | (1) Sulphuric or phosphoric acid. (2) Probably a phosphate, as sulphates never afford these "streaks," but only generally diffused, grey, opalescent matter. |
| II. Powder fused with $K_2O$, boiled, dried, and treated in B acid. (1) Whole powder white opaque balls. | (1) Calcium (probably) phosphate (magnesium borate is similar, but balls clarified by long treatment). |
| III. Dissolved these by cautious addition of $K_2O$, and added potassium pyrotungstate (*g*) in excess, under H. P. (*h*). (1) A turquoise blue opaque bead. | (1) Phosphoric acid in large proportion; because part must have been previously removed by fusion with alkali. |
| IV. (*i*) Powder of mineral on the copper-wire B acid bead. (*j*) (1) A brilliant but momentary cerulean, or light blue colour. | (1) Chlorine as copper chloride, which has a blue p.c. |
| V. Powder of mineral with crystal of P acid, and drop of water heated in glass bulb. (1) No dulling of the polished neck of bulb. | (1) No fluorine. |

What mineral is this?

*Notes.*—*a.* This reaction constitutes another valuable distinction between carbonates and sulphates; bubbles disengaged from the latter lasting, in every case, at least double as long as those from the former: no carbonates of the alkaline-earth metals refuse, as far as I know, to speedily separate into balls and bubbles under this treatment, like the sulphates of barium and strontium.

*b.* This indicates that the *specific gravity* of the metal forming the carbonate is greater than that of those which form perfect larger sphericles; as, *e.g.*, calcium, magnesium, &c. These balls being produced through the law of the cohesion of fluids, larger ones of high sp. gr. are not round on account of the attraction of gravitation overcoming that of cohesion: just as the larger drops of mercury, scattered on a table, are not round, while the small ones are.

*c. Vide* ENGLISH MECHANIC, page 478, note (*b*).

*d.* It may be asked here, Is not this effervescence due to $SO_2$, not $SO_3$, as the latter is not known (practically, until here produced) in the form of gas? To this I reply it is certainly not $SO_2$, which has a pungent smell, whereas this is odourless.

*e.* This is the chemical formula for potash, used for brevity's sake, as before explained, for the ordinary potassium carbonate; as, of course, potash only is added to a bead B.B. the $CO_2$ being volatilised. I nearly filled my bottle with a pennyworth obtained from a druggist here. It is tested (1) by boiling in distilled water, when it ought to leave no residue, (2) by giving a violet p.c. *per se* B.B., (3) by not in the least altering the green p.c. of B acid B.B. (no soda.)

*f.* A "Mineralogist" (who, I must admit, has made pretty fair guesses at these minerals hitherto) states, "E. M.," page 498, that he found strontium sulphate to afford precisely the same reactions in E acid as barite; but if he will be so good as to analyse the former carefully over again, I think he will find the differences recorded here between Nos. 14 and 17.

*g.* See note *a*, "E. M.," page 431.

*h.* See note *e*, "E. M.," page 478.

*i.* This operation is induced by the *mineralogical* knowledge that this mineral, here proved to be a phosphate of calcium, generally contains chlorine or fluorine.

*j. One* bead ready for use may be kept months for this purpose on a roll of ordinary copper wire, provided the bead be previously tested B.B. to see that it contains no chlorine, which is rapidly thus driven off on account of its extreme volatility.

W. A. Ross.

## WHAT IS CREATION?

[24662.]—In letter 24590 a "Fellow of the R.A.S.," replying to "H. B. F.," *re* What is Creation, puts the whole matter in a nutshell most beautifully. Darwin's explanations and theories, founded upon the work of a lifetime, showing evolution, adaptation, natural and sexual selection, &c., all working together to bring about changes in existing matter, are met by his opponents simply with crude assertions—viz., such phenomenon cannot be explained, say, by natural selection—ergo, this, at all events, must be ascribed to "creation."

If a simple man demands to have an explanation of what "creation" signifies, why, either he is snubbed as an unbeliever, or ignored as a man not worthy a reply. Of course, the idea of creation *ab initio*—something out of nothing—is at present largely abandoned; but the logical consequence quietly ignored—viz., that if all phenomena are only the change of matter in one state into another, i.e., a simple transformation, "evolution" is at once seen to be the proper name for such a process. Of course, to postulate for "creation" and consequent "Creator" sounds grander; but, to my mind, it simply substitutes a greater mystery for a smaller one.

F. W. H.

## LANTERN SLIDES.

[24663.]—I WISH to ask the readers of the ENGLISH MECHANIC their opinion as to the desirability or otherwise of having slides for the lantern uniform in size.

In the first place, it is practically imperative that they should all be of one height—3¼in.—as otherwise they would not pass through the carrier.

Still, even then there is a difference of practice as to length or width, which is 3¼in. for the ordinary photographic slide, something under 4in. for the Benet photographic slide, and 4¼in., which is the usual quarter-plate in photography. These three sizes exist commercially, but they are all 3¼in. in height, and therefore will pass through the carriers with more or less difficulty with respect to registration on the screen.

It is no use discussing the question of uniformity of length or width, for these slides exist in such quantities that they must be dealt with as best the exhibitor can. Whatever the size of the glass, the pictures are all approximately the same size, somewhere about 3in. in diameter. It is more particularly to uniformity of this measurement that I would draw attention and invite discussion.

My plea is that, so long as the picture is fully lit all over by the condensers, and that the glasses do not exceed 3¼in. in height, the size and shape of the mask should be discretionary. I protest most strongly against the practice of masking all sorts of slides with uniform masks for the sake of uniformity of shape on the screen. This makes them lantern slides, but it prevents them from being lantern pictures.

I have long determined myself to compose my pictures for the lantern, but have found it quite impossible to adhere to either the 3in. circle or 3in. cushion shape without, in many cases, spoiling the picture.

I have also a unique collection of negatives of the Congo river and Central Africa sent me for publication as lantern slides. These are pictures carefully composed, and in many cases will not admit of the slightest curtailment of length so as to bring them in the uniform category of lantern slides. I could not attempt to do this even if I would, for though some might have a vast extent of sky printed in to fill up the frame, in others this treatment would be impracticable. They will have to be printed oblong, and must be shown so or not at all. I anticipate objections on the score of difficulty of register in dissolving with two lanterns. This I would venture to dispose of by saying that most people are heartily tired of dissolving views. I think, too, that this objection might be met in another way—by so arranging the dissolving apparatus that the picture fades away into darkness before the other one commences to appear. This, I should be glad to learn, may have already been done; certainly it is a most agreeable way of changing pictures on the screen. The same principle is found in Edwards' patent dissolver, which works with a single lantern, the first picture fading away into darkness, from which the new picture instantly appears. The form of dissolver most suitable is that known as the cat's eye; two angular apertures, hexagonal the best, the apices being an angle of 90° and the lateral angles 135° each. As the apertures pass over other each other the picture gradually fades, but more from the edges. This is a great advantage, for the spectator has completely forgotten, not only the shape of the picture just shown, but its position on the screen. Moreover, although with Edwards' dissolver there is a slight interval of darkness, during which the slide is changed, the rest to the spectator's eye is so complete that not only is the darkness not perceived, but he is also quite unable to detect an error of registration of even 6in. on the screen; while circular, square, oval, or oblong pictures can be shown indiscriminately without the slightest inconvenience or fatigue to the eyes of the spectators.

I assume that 4in. condensers are used; they are the standard size, and any lantern having smaller ones is but a toy. This being allowed, the screen being of such a size that it will take the whole of the disc lighted by the condenser, then I contend that the picture might with advantage be made of any size which would fall within such a circle.

One word more as to light: There is no greater mistake than to suppose that a denser slide is required for limelight than for oil light. A slide of proper density will be equally effective with either light, no matter what the size of the disc. Let me be clearly understood: a slide which is at its best when shown by an oil lantern on a 6ft. disc will be equally effective when shown by the most powerful limelight, whether on a 6ft. disc or 20. Any slide which will not bear that test is inferior and comparatively worthless. **George Smith.**

26, Colebrooke-row, N., 11th Aug.

### VENTILATION OF COAL-MINES.

[24664.]—Perhaps Col. Shakespeare will kindly give his views on the following points in connection with the opinions he has from time to time expressed on the above subject:—

(1) In what way does he suppose that the liberation of 50,000 cubic feet, say, per minute of compressed air expanding in volume to 200,000 cubic feet on liberation, would have the advantage of the same volume of air per minute being drawn through the workings of a colliery by means of a fan or furnace?

(2) The estimated horse-power that would be required to compress the above quantity of air, the approximate cost of the necessary plant, including the few miles of pipes to convey the air throughout the ramifications of the working, and the additional cost per ton of coal wrought which such a system of ventilation would entail.

The proper and adequate ventilation of our coal mines is a matter of paramount importance, and I, and doubtless many others of your readers, will look forward with much interest to Col. Shakespeare's reply to the above questions. **Lyons.**

August 11th.

## REPLIES TO QUERIES.

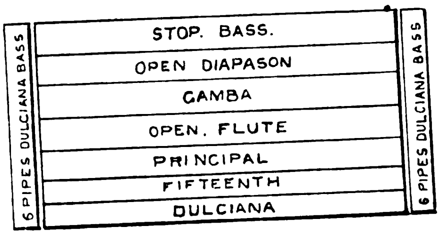
*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[56273.]—**Chemical Action in Leclanche.**—The zinc combines with the chlorine of the ammonium chloride, turning out the compound radical ammonium, and forming zinc chloride. The Am is transferred in the usual way till it gets to the $MnO_2$, here it decomposes into ammonia gas which dissolves in the water, and hydrogen which reduces the manganese dioxide. In one equation the action may be given $Zn + 2AmCl + 2MnO_2 = ZnCl_2 + 2NH_3 + H_2O + Mn_2O_3$.—Wm John Grey, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56518.]—**Organ Building.**—To "Anxious."—Having recently built myself a small organ (five stops on manual, and full octave pedal bourdon), I have pleasure in offering reply to the questions as far as I can, though I should have preferred seeing a reply from some reader of wider experience. For a five-stop organ I would recommend three 8ft., one 4ft., and one 2ft. stop; and add another 8ft., to make six. (This means one more draw knob in either of the above, because of the stopt diap. bass on a separate slider, and an additional draw-knob, if the dulciana bass is placed separately.) If a *coupler* is intended, the soundboard must be 6in. longer if you carry out your intention regarding the 8ft. and 4ft. stops, so as to allow the extra 12 channels for the upper octave; but having a 2ft. stop specified on the manual, I should only make the coupler for the 42 notes—Tenor C upwards. The specification I suggest is thus:—

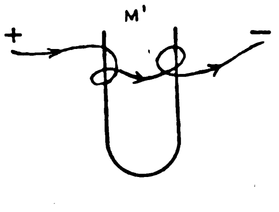
| | | | |
|---|---|---|---|
| Open Diapason | Metal 8ft. | C. 42 | pipes |
| Stop Diap. Bass | Wood 8ft. tone | CC. 12 | ,, |
| Stop Flute | Wood 8ft. tone | C. 42 | ,, |
| Dulciana | Wood and Metal 8ft. | CC. 54 | ,, |
| Gamba | Metal 8ft. | C. 42 | ,, |
| Principal | Metal 4ft. | CC. 54 | ,, |
| Fifteenth | Metal 2ft. | CC. 54 | ,, |

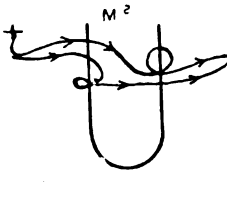
To reduce it, omit gamba. In your query, the dulciana is erroneously called a 4ft. stop. It is an 8ft. stop. If you wish to carry it through, make the bass of wood, stopped; scale, ¾in. by 2¾in. for CC. These you can place six at each end, using tubing to convey wind to them as well as to the treble pipes in the front. Plant the stop. diap. bass in a row on the soundboard at the back. Two at each end will stand on their own wind; the remainder to have grooves and tubing to supply them. I should say that with this arrangement it will be necessary to get a rollerboard action for six bass pipes, commencing with CC sharp, and then the remainder alternately; so that you will have six bass pipes each of the stop diapason, dulciana, principal, and fifteenth on the treble end of soundboard. The front dulciana pipes may be cut at the back for the purpose you name. If the organ is for a small building, I suggest the following scales:—Open diap. 2⅝in.; gamba, 2¼in.; and dulciana, 2in. at Tenor C. Principal, 2¼in.; and fifteenth, 1¼in. at CC. Pressure of wind better be 2½in. for the pipes to speak well. I should prefer feeders hinged on the front of bellows-board, so as to have pedal and hand-blower actions working at the back. You may get the feeders to work steadily by fixing a support at the back for a lever centred on a pin, with wood rods connecting to feeders. Make a socket at one end of the lever to take a movable handle for side-blower. Make the pedal-blowers like those of a harmonium, with wheels under feeders. To keep down the height of the organ, let the pipe feet of the six longest stopt diap. and dulciana bass project only an inch out of the block, and support the pipes by a wooden cleat screwed on the back to slip on a cleat-hook on a wood rail fixed as necessity may require. As an improvement, I would suggest, if you wish to have the dulciana as a "speaking front," that all the other stops be inclosed in a general swell, having Venetian shutters in front worked by a knee-swell lever. Let the bellows and feeders be, if anything, more than ample to supply full organ; possibly you may some time wish to add a pedal Bourdon. Do not count time devoted to securing correct measurement as time lost; it will prove ultimately time saved. Herewith I give rough sketch of the



arrangement of the sliders. I ought to say that I am supposing the key action to be by stickers, with back falls in a fan frame.—A. Evans, Bank, Llandudno.

[56649.]—**Extra Currents (U.Q.), and Testing by Received Currents.**—This query seemingly has escaped "Sigma's" notice, and having fallen into the U.Q. column, I beg to offer a few remarks to telegraphists. *Extra Currents.*—We will dispense with the automatic receiver, with its rather complicated double-wound multiple arc arrangement, and take an ordinary electro-magnet M, for what is true for one is true for the other. I inclose a rough sketch. We will suppose that





the battery current has just been broken, then the extra current travels in the direction of the arrows M¹. The arrows are not intended to show the battery current, but simply the extra current when the battery has been broken. Again, in the multiple arc arrangement the battery current is supposed to be just broken. The extra current travels in each wire in the direction shown M², when they meet at the point P, their forces being equal and opposite must of necessity destroy each other. I hope the rough sketch and poor description will be acceptable. *Testing by Received Currents.*—The current from the distant station is sent through 10000 + 10000, so that the variable resistances (battery and leakage) may be neglected. The higher the tangent the greater the insulation of the line. I suspect that the table contains a column of tangents opposite to which are the equivalent insulation R's, so that the c.c. can see at a glance what tangent 20, for instance, represents in insulation R. I don't know if I have gone sufficiently far into the subject to meet your requirements; but if not, write again and I will endeavour to give you satisfaction.—Experimenter.

[56768.]—**Ancient Lights (U.Q.)**—The following is from "A Guide to the Law, by a Barrister": —The owner of property is entitled to as much light and air only as fall perpendicularly on his land. A man is liable at any time within twenty years to have any new windows obstructed by his neighbour building against them. Neither a landlord nor a tenant can obstruct or darken windows existing at the time of the demise without each other's consent. If ancient lights are altered or enlarged or new ones are added, they may be wholly obstructed, and a man is justified when in obstructing new lights he unavoidably obstructs the ancient ones as well. From this it would seem that if the windows "X. Y. Z." wishes to build against have been in existence for twenty years he had better not obstruct them unless he can prove they have been enlarged within that period.—Zinci Sulphas.

[56790.]—**Limited Liability Company (U.Q.)**—There have been many vague questions asked in the query columns of the "E.M.," but "Klinkerfues" may fairly claim to have made the highest possible score with this query as to the "general duties of the managing director of a limited liability company."—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56888.]—**Bicycle Turning.**—I do not think that "Essar" quite understands me. In turning a corner the small wheel does not follow the large one—I mean on the same track. As soon as the handle is turned, the vertical planes of the large wheel, and of the backbone and small wheel, are at an angle, the small wheel describing a smaller arc. The touching the ground only in points is good in theory; in practice, owing to the weight, the elasticity of the tyres, and the uneven surfaces of the roads, the contact might be of ¼in. or ½in. I maintain, therefore, that the hind wheel must "drag" to a certain extent. Yet if "Essar" stands on a grass lawn, and locks the handle of his bicycle as far as it will go, and walks it round, he will find that the large wheel track forms a perfect circle, and the small wheel forms one also about 6in. within it, perfectly true to the same centre, without any signs of a drag.—J. R. T.

[56923.]—**Bleaching Shellac.**—While thanking "Nun. Dor." for his reply to my query as above, I should like to say I have tried several times to bleach shellac by a process given to me by a friend. Each time I have failed, and have not now that friend to set me right (he being dead), hence the query to the "E. M." The process is similar to that referred to in 991 of "E. M.," and is as follows: Dissolve 14lb. shellac in about 12 gallons boiling water containing 2lb. chloride of lime, stir well, and let stand two or three days; then add 1 pint hydrochloric acid, strain through flannel, keeping stream of hot water running on it all the time; when well washed, take shellac out and pull on a hook until white and silvery, occasionally placing it in hot water to assist the operation. As I have said, I have tried this process several times and failed. After reading the process referred to in 991, it occurred to me that perhaps the success of the whole thing lay in "cementing the air-tight cover while hot." I have not the least idea what "any ordinary luting" means. Should it be putty, or something of that kind, perhaps "Nun. Dor." will set me right on this and other points in my query, or kindly set me right altogether by giving a process with which I may be more successful. I require it for making sealing-wax (the brightest colours), and should require it solid.—J. L.

[56948.]—**Gas-Producing Apparatus.**—The statement as to risk of explosion refers to the benzoline generator made by me. The safety-box contains twelve layers of thick copper gauze, soldered tight at the margins. I have been unable to produce any explosion which will pass through four thicknesses of copper gauze, and I believe the apparatus to be absolutely safe, with a very large and unnecessary margin of safety under any possible conditions. I will sit on any of my generators whilst "Invicta" or anyone else does his best to explode it.—Thos Fletcher.

[56950.]—**Lead Burning.**—It is quite certain to us that Mr. Davies does not understand the merits of, as he sarcastically terms, our "wonderful machine." We have never pretended to say that the flame given is superior to that given by the machine made with spelter and acid. All we wish to claim its superiority over the old method for is that it is easy to carry about, and can be used anywhere "with safety," and that it is always ready for use. Mr. D. has certainly obtained an insight into the mode of working the apparatus, but it is certain he does not fully understand it. Surely, we would have adapted the water-bellows he speaks of if it had been any benefit to our apparatus, considering we used a similar one some 18 years since. This apparatus with the acid machine does very well for shop work, and is used in almost all chemical works. When we submitted our exhibit at the Inventions to the jury we were asked to show the flame to them. They were perfectly satisfied that the force of the flame was sufficient to melt the solder and to "burn lead," for which we are happy to say we have been awarded a "medal." We have written to Mr. Davies, if convenient to him, to meet us at his workshop on Saturday next, when we trust we shall be able to convince him that he has been mistaken as to the merits of our apparatus.—Briggs and Co., 58, Rokeby-street, Stratford, E.

[56956.]—**Ball Bearings.**—Mr. Hosken has probably failed to see the questions I put to him on p. 481. Will you allow me to add another? which is, whether he ever calculated what a bicycle, with bearings two and a half diameters of the axle would be like? Mr. Hosken betrays more than he thinks when he asks why "railway engineers don't apply ball bearings to railway carriages"? Let me have another question, and ask him Why they should? They know their business, and so do bicycle-makers. As an "engineer," Mr. Hosken advises plain bearings made "broad enough, with the patent needle lubricator." What is the "patent" needle lubricator? The patent ran out years ago, and nobody but Mr. Hosken would advise a needle lubricator for a bicycle or a cycle of any sort. However, I am still waiting for the name of one "first-rate rider" who is opposed to ball bearings. —Essar.

[56956.]—**Ball Bearings.**—As none of your correspondents seem to know why ball bearings are so satisfactory on cycles, and yet not applicable to other vehicles, I will endeavour to explain, the two wheels of a bicycle serving as an example. In the large wheel, the axle revolves and imparts a rotary motion to the balls, slower or about the same rate that it revolves itself; in the small wheel, on the contrary, the balls are carried round the axle by the hubs, and do not rotate on their own axis, the same taking place with ordinary vehicles that have a fixed axle, the consequence being that where there is much weight the axle gets cut to destruction, the balls acting as so many knives; and most bicycle riders must have noticed that the big wheel runs much smoother and quieter than the small one. I think Mr. Hosken said in a former letter that the balls grate and grind one another away. They would if packed in close together, as they used to be when first introduced; but now they leave a space of about half a ball in each row, and some makers keep the balls apart by means of a perforated brass cage.—G. Townshend.

[56957.]—**Ball Bearings.**—I have ridden bicycles with broad plain bearings made with the greatest care. They run nearly as easily as ball bearings when clean; but they require adjusting often, and they grind away. In my experience good ball bearings in a bicycle will wear as many years as good plain, broad bearings will wear months. If Chas. Hosken will consider the size of ball bearings used to carry a rider of 160lb. weight, and calculate the size required to carry a crank-shaft and fly-wheel of, say, 10 tons, he will know one reason why plain bearings are used for machinery. If he will consider the action of grit on the two classes of bearings he will understand the other reason—i.e., that ball bearings will run when full of grit, and plain bearings will not. Ball bearings grind the grit, whereas the grit grinds the plain bearings.—T. F.

[56997.]—**Hydropathy.**—As "Quixote" has not received any direct answer to his query, I will try to supply him. In the first place, the cold-water cure is a thing of the past, and should not be recommended as a first step in the cure of any complaint; such a course of mild treatment that will bring about the cure, and then your cold-water tonic, &c., if you like. The cold-water cure originated with Priessnitz, Germany, who performed some wonderful cures in some cases, but with some he made sad mistakes by not using a milder treatment. Dr. Wilson introduced it into England, but in a modified form, and it has now become a curative art. Should "Quixote" decide to go to an establishment, I would say by all means go; but I may tell him it is expensive—two to three guineas a week for able treatment, and a week or two's stay would really do but little for him. It just amounts to this, temporary relief; but, according to my experience, from four to six weeks to effect a cure. I was under treatment at Smedley's, Matlock Bank, several months, and was a careful observer during that time. I have practised it as home treatment over twenty years, and although I had taken gallons of medicine before then, I can promise you I have taken very little since. I beg to refer "Quixote" to some remarks in "E. M." of January and February last, and if, according to my experience, I can give him any useful information, he is welcome to it, or any other reader. Of course this would take more space than could be reasonably asked for here, as I should require more particulars from him; after that I would give him, out of a list of some two hundred, a course of baths suited to his complaint. This can only be done upon receiving careful particulars, and if he has a will he may practise hydropathy at home very successfully, and I would willingly supply him from time to time with any information he may require. He will now see that he has begun the wrong way about, and if he choose to advertise his address I will put him right. But let it be borne in mind that anything I say is intended only for such that are partially or wholly without any knowledge of hydropathy. I have at length completed my improved H.A. bath, which I have made mention of in these pages some months back. It is a complete success, and will willingly give description of it in "Ours" if requested to do so.—A Hinckley Man.

[56998.]—**Vibration from Steam Hammers.**—Stand the legs of the bedsteads on thick blocks of vulcanised rubber—bits of old valves will do. That is about the only thing: it will reduce the vibration, but not eliminate it, because the whole ground shakes in the neighbourhood of steam hammers.—Nun. Dor.

[57002.]—**Voltaic Cell.**—This querist will find what he wants by searching back numbers, and on page 482 "Sigma" explains the rationale. The querist, however, will act wisely by using the Léclanché cell for his electric bells.—Nun. Dor.

[57004.]—**Grinding Machine for Polishing Sheet Iron and Steel.**—"Tool Maker" ought to find no difficulty in buying emery wheels, and he can soon settle for himself what speed they ought to run at for polishing. I never knew there was any definite speed, but I suppose the quicker the thing goes the sooner the work is done.—Essar.

[57007.]—**Fishing-rod Joints.**—The best composition is no doubt marine glue, but probably Prout's will answer. The best varnish is stoved copal.—Essar.

[57016.]—**Am-meter and Volt-meter.**—This querist can find what he requires by looking up his back numbers.—Nun. Dor.

[57028.]—**Stamping in Relief.**—"Inquirer," for information on above, feels under deep obligations to "Os" for his very kind and lucid explanation, and, if not troubling him too much, "Os" would still further kindly reply to two or three queries. "Stamper" feels quite sure he could master the process, and gain considerable advantage over his future supplies, and feeling thereby deeply indebted to "Os" and the Editor for their great kindness. How is the lacquer for the tickets made? Does "just hot enough to hold" mean to be held by the hand, or to hold the lacquer? Would the same press be likely to do for the tickets and for stationery, with a different die?—No Sig.

[57049.]—**Gramme Dynamo.**—To Mr Bottone.—In consideration of the peculiar shape of the fields, which necessitates the ring being flatter than usual, the ring would be better if made of such a diameter as just to revolve between the pole pieces without touching them. The pole pieces may approach to within 2in. of each other, and take the form of a letter C, thinning off somewhat where they are nearest to one another. Greatly enhanced effects would be obtained if the pole pieces were deeply channelled, and the ring made in section like a letter ⋒, the rounded part running in the channel. At least 12 sections should be laid on the ring, the substance of which should be about ½in., except at the cogs, where it should be about ⅜in. thick.—S. Bottone.

[57055.]—**Electric Bells in Series.**—I am experimenting in this direction, and if I succeed in making my bells ring properly (I believe I shall do it) I will send in an account of my plan.—Zinci Sulphas.

[57072.]—**Siemens Alteneck Armature.**—Will Mr. S. Bottone kindly explain the principle how the winding of the wire on the above-named affects or magnetises the core, and also the reason that the ends of the wire are so curiously joined to the commutator? I have traced them out in your sketch—viz.: 1 + 1′ to E + F, 3 + 3′ to B + C, 5 + 5′ to C + D, 7 + 7′ to D + E, 8′ + 8 to H + A; then 2 + 2′ 4 + 4′ seem to be joined quite on a different principle, unless there is some error in the sketch. Would this gentleman please give the full particulars how to make an armature of this description?—A Very Old Subscriber.

[57122.]—**Problem.**—I am sorry to see that in my reply to this last week I have altered the lettering of the diagram, not observing that, to save space, it had been turned on its side. Instead, therefore, of $\angle CAB = \angle CEF = x$, I should have written $\angle ACB = \angle AED = x$, and for B C, the height on the wall, I should have written A B. The result remains unaffected.—W. A. S.

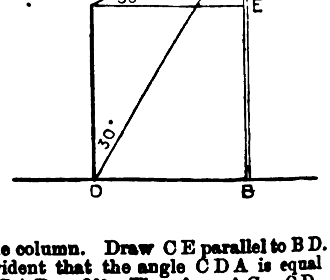
[57124.]—**Lifting Bar.**—Work in dynamics (or kinetics in the new nomenclature) being the effect of the action of a continued force with (or having) a continued motion and being measured by the product of the force and the space through which the force moves, it is true that when the bar is simply supported in a horizontal position by the hand at one end of it (or at any other point) without motion, no work is being done. It is also true that muscular force can be altogether exhausted without motion, and therefore without doing work. A man simply supporting a weight on his back without motion is not doing work according to the above-received definition of work. Without motion both the above cases belong to statics, for in both cases the muscular force employed only resists motion; but in the original case it produces motion in lifting the bar four feet and resists motion round the centre of the hand, and the case belongs partly to kinetics and partly to statics.—J. S. C.

[57128.]—**Storage Battery.**—I fancy from what "Werdna" says in the last issue, he is thinking of an accumulator of the Planté type when he mentions a lead plate coiled up into a spiral. If he wishes to make one of that kind, the best way is to take one sheet of lead and lay it out flat, and then place thin bars of wood across the 4in. way at short distances apart, and then place the other on the top and roll them up together, taking care that they do not touch anywhere. A strip of lead should be left projecting at the end of each plate for connection, and two sticks of wood should be laid across the bottom of the jar, or some similar device adopted, to prevent the lead plates touching the bottom, as, if they do touch, any deposit on the bottom may short-circuit the cell. The plates had, I think, better be made as long as possible, being one-third of an inch apart. Before formation is begun they should be placed in a solution of nitric acid; equal parts of acid and water. I do not know so much of the Planté as of the Faure type; but I think five or six cells of the above form would answer the purpose. These take longer to form and to get into working order than the Faure. The lead must be about one twenty-fifth of an inch thick. Read what Sprague says about these in his "Electricity."—Bunsen.

[57129.]—**Steam-Engine for Farm Work.**—I could not tell you how much power is absorbed by the gearing and shafting, but I think it must be small. The size of engine you mention is larger than I expected, and, I am afraid, beyond my powers to fit up with present tools. Supposing only one of the machines was driven at once, the engine could be smaller. The churn could be driven direct from the engine, causing less friction, and only one large pulley would be required to bring up the speed of the thresher. Scotch coals are 11s. per ton, *ex* ship. English slack 8s. per ton, both exclusive of carting. Would the new motor you speak of be powerful enough for my work? I suppose it is patented; then how could I make one for myself? Would it not cost more than an engine and boiler? I have no doubt it would be very handy, and from what you say it would do well for driving my workshop appliances. Do you refer to helping me with this motor, or a steam-engine. I am greatly obliged for the trouble you have taken, and shall be glad of any more help you can give me. —Young Farmer.

[57142.]—**Planing Machines.**—The only machines which will work by treadle are those sold by Selig, Sonnenthal and Co. These machines appear to be the same as those patented in this country by M. Haas. They have two pinions, one for the cutting, and the other for the return motion. The pinions are thrown in and out of gear by means of compound or double clutches, which are alternately in gear by means of a spring; the rack is made to slip about 1in. to avoid a jolt. The planer being patented, W. Bundy cannot make it; but if a screw-driven machine will do, I can give you designs of my own, which, as far as I know, are not patented. Advertise address if you want them.—F. Shakespear, Dresden.

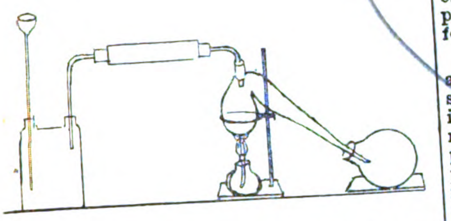
[57164.]—**Trigonometrical.**—In the accompanying diagram let A B represent the tower, and C D the column. Draw C E parallel to B D. Then it is evident that the angle C D A is equal to the angle C A D = 30°. Therefore, A C = C D. Now, in the right-angled triangle A C E, since C A E = 60° and ∴ A C E = 30°, therefore A C = 2 A E = C D = B E, and hence C D = $\frac{2}{3}$ A B = $\frac{2}{3}$ × 108 = 72ft., the height required.—J. E. Gore.



[57159.]—**Watch Query.**—The cause of your watch gaining may not be the spring, but the escapement, which is too shallow. If this is all right, the spring is three or four sizes too strong, and must be changed. To find the diameter of the spring, you must place it on the plate so that the centre of the spring is over the staff-hole, and notice where it would enter the hole in the stud. Now place the spring over the staff, and put a small piece of cork or wax on the pivot to keep the spring down. Take hold of the spring with the tweezers about where it has to be pinned in, and raise the balance. A slight movement of the hand will cause the balance to vibrate up and down. If the watch has an 18,000 train, the balance should make five vibrations in a second, or if a 16,200 train, four and a half. If this does not suit you, write again.—C. A. W.

[57166.]—**Model Well.**—Probably the bend of the siphon pipe goes through a water-tight hole in the side of the cistern, so that when the water rises above the hole the siphon bend is completely filled, and the water is siphoned off to the level of the bottom of the siphon pipe within the cistern, and this takes place again when the cistern is again filled by the smaller supply pipe.—W. Scudamore.

[57170.] — **Pure Phosphorus.**—To Mr. Bottone.—All that is required is a Wolf's bottle, in which are placed the necessaries for the



generation of carbon dioxide (chalk and hydrochloric acid). The escaping gas is led through a chloride of calcium tube to dry it. From thence it passes into the retort, wherein is placed the phosphorus which is to be redistilled. Heat is applied to the retort, when the phosphorus volatilises and is collected in the receiver under water.—S. Bottone.

[57173.]—**Easing Force Pump.**—I suppose your force pump is a lift and force of the usual make. Now, the question here is the tremendously hard work expended in forcing or lifting the water; if in forcing, an air-vessel will certainly improve it. *But I think* it is a case similar to what I experienced about 12 months ago. I made up and put down two pumps 2¼in. bore to lift water 25ft., and force it the same height, and I assure you it was very hard work indeed to lift the water, but not so to force it. So I made an alteration in the pumps, with the most astounding results—namely, that of the pumps lifting their own water and handle automatically, and only require forcing. The smallest child can work them with ease.—Pump Patent.

[57177.]—**Soldering.**—If you will kindly look over the first and second articles on "Electrical Instrument Making for Amateurs," now appearing in this paper, you will find full instructions under the heading "Soldering."—S. Bottone.

[57180.]—**Winding Laminated Armature.**—To Mr. Bottone.—The projecting shaft throws the wire on each side of itself (i.e. the shaft). But this is easily remedied by turning up the two first,

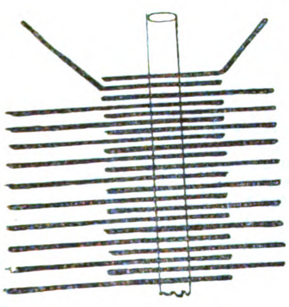


FIG. 1.

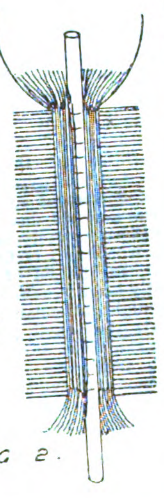

FIG 2.

and two last laminated, as shown at Fig. 1, so that they act as supports to the displaced wire, as seen at Fig. 2.—S. Bottone.

[57181.]—**Heating Greenhouse.**—"Thermo" would no doubt succeed with a slow combustion stove; but great attention would, I imagine, be necessary, as, without an evaporating pan for water, the air of the house would become far too dry for the plants. Dust and smoke are also inseparable nuisances. "Thermo" would find one of the cheap stoves with a "coil" boiler answer well if he has an outhouse or protection for the stove; or one of the "Loughborough" pattern (in which the boiler is built into the wall of the greenhouse, so that most of the heat is utilised, while it can be stoked from the outside) would be found very serviceable, and would, I think, satisfy 'Thermo" in every way.—J. T. Strange.

[57189.]—**Income Tax.**—"Os" is wrong; the tax is not levied on individuals, but on the firm or partnership. I, as a member of a firm, pay no Income-tax; this is paid on the whole profits of the business, and not by the individual partners. In the same way the Income-tax is paid on the whole dividend of a company, and deducted from each shareholder's dividend.—T. F.

[57193.]—**Balance Staff.**—A thorough reply to your queries would occupy more space than our Editor might care to allow; but I can refer you to a recent work invaluable to watchmakers wishing to learn—viz., "Britten's Watch and Clockmaker's Handbook, Dictionary, and Guide," 5s., to be had of all material dealers. The turns, turning, pivoting cylinder, and balance staff, &c., will be found admirably described in this book.—L. T. P.

[57193.]—**Balance Staff.**—You must first make a number of small holes in your runners to hold the staff, &c.; these can be made with a small chamfering tool. It is better to file part of the left-hand runner away, so that it comes to something like a point, and make the hole at the end of this. To put in a staff, first get some from the dealer in the rough; they are very cheap, and it saves a lot of trouble and time. Put a screw ferrule on one end and place it in the turns; fit the points of the staff into the holes in the runners. First turn down a shoulder on the brass to fit in the balance, and then reduce the remainder of the brass to fit in the collet. Turn the steel until the roller will go nearly up to the brass, and then polish it. Now shorten it until it is nearly the right length, which you can ascertain by placing the balance on the shoulder which you turned, and putting the centre of the staff on the potence slip without the jewel-hole in. When this is correct, turn the pivot down; when it is nearly small enough, place it on a brass runner and polish it with a soft steel polisher and red stuff; when it fits the hole well, round the end of the pivot, using a runner with a very thin edge in which a small hole is drilled for the pivot to come through; round it with a burnisher. Take the ferrule off and put it on the finished end, and make the top pivot the same as you did the bottom. When finished rivet the balance on: Pinions should *not* be oiled.—C. A. W.

[57197.]—**Watch Springing.**—Send the barrel to the material dealer, and order a best mainspring. State whether the spring is for a verge, duplex, lever, or horizontal watch. If you send your dimensions you will not get a suitable spring, and if you send your spring it may be the wrong strength or height for the barrel.—L. T. P.

[57197.]—**Watch Springing.**—I suppose your gauge has a number of different-sized cuts or openings in the edge. When the spring is out of the barrel, try which one of these openings it will go in. The number below this opening is the height of the spring. To find the strength, use a steel gauge, with two pieces of steel which are wider apart one end than the other. Put the spring between them at the wide end, and try how far it will go down. The numbers on the edge of the steel bars will tell you the strength.—C. A. W.

[57207.]—**Electric Lamp.**—You must test it. It may be 20 candle-power or 2. What size is it?—C. D. R.

[57207.]—**Electric Lamp.** — Get some kind friend who has a Wheatstone's bridge and coils to test the resistance for you. A five-candle lamp has a resistance of about 8 ohms, a ten-candle 20 ohms, a fifteen 37½ ohms, a twenty about 48 ohms.—S. Bottone.

[57207.]—**Electric Lamp.**—"Plumber" can only ascertain for certain the c.p. of his lamp by comparing its full light—by means of a photometer—with that of a standard sperm candle.—J. Kean, Northampton.

[57209.]—**Case-Hardened Iron.**—Place them in a crucible imbedded in powdered prussiate of potash. Wire the lid on the crucible, and give it a good cherry-red heat right through.—S. Bottone.

[57209.]—**Case-hardened Iron.**—Heat the iron studs to dull redness in the fire, roll them in a powdered mixture of equal parts of sal-ammoniac, saltpetre, and yellow prussiate of potash; wait a few minutes till the heat has had time to decompose the powder, and then plunge into a solution of 4oz. of sal-ammoniac and 2oz. of yellow prussiate of potash dissolved in a gallon of rain water.—W. Scudamore.

[57213.]—**Hydrostatics.**—As 92 parts by weight of the ice and 100 parts of water are equal in volume, and as floating bodies displace their own weight of water, it is clear that 8 per cent. of the volume of the ice will be above water. The thickness of a sheet of ice of sp. gr. 92, and which floats ½in. out of water, is found by the following proportion:—8 : 100 :: ·5 : $x$; $x$ = 6¼in.—J. T. M.

[57213.]—**Hydrostatics.**—Since sp. gr. of ice is to sp. gr. of water as 92 is to 100, therefore 92-100ths of the thickness of ice would be below, and 8-100ths above the surface of the water. Therefore, since 8-100ths of the thickness equal ½in., the thickness $= \dfrac{100 \times \frac{1}{2}\text{in.}}{8} = \frac{50}{8}\text{in.} = 6{\cdot}25\text{in.} = 6\tfrac{1}{4}\text{in.}$ Answer.—W. Scudamore.

[57213.]—**Hydrostatics.**—Let $b$ = breadth of sheet of ice, and $x$ = thickness. Then, since the weight of a floating body is equal to that of the fluid displaced, we have—

$$\begin{aligned} bx \times 0{\cdot}92 &= b(x - \tfrac{1}{2})\\ \text{or—}\qquad 0{\cdot}92x &= x - \tfrac{1}{2}\\ \therefore\text{—}\qquad 0{\cdot}08x &= \tfrac{1}{2} \text{ and } x = 6{\cdot}25\text{in., the} \end{aligned}$$

required thickness of the ice.—J. E. Gore.

[57213.]—**Hydrostatics.**—The weight of the ice and of the water displaced by it are equal. The volume (or bulk) of the ice and of the displaced water are inversely proportional to their sp. gr., and directly as their thickness and depth. Let $x$ be the thickness of the immersed part of the ice, or the depth of the displacement, then $(x + \frac{1}{2}\text{in.}) \times 92 = x \times 100$, or $92x + 46 = 100x$, or $100x - 92x = 8x = 46$, or $x = \frac{46}{8} = 5{\cdot}75$in.—J. S. C.

[57213.]—**Hydrostatics.**—Let $x$ = the thickness of ice below water, and $a$ = the sectional area of the sheet; then we have the following equation:—

$$\begin{aligned} (\tfrac{1}{2} + x)\, a \times {\cdot}92 &= x \times a\\ \therefore {\cdot}46 + x\, {\cdot}92 &= x\\ x &= 5{\cdot}7\text{in.} \end{aligned}$$

But there is ·5in. above water; therefore, the total thickness of ice is $(5{\cdot}7 + {\cdot}5) = 6{\cdot}2$in.—H. L. C.

[57214.]—**Electric Bell.**—2oz. No. 26 silk c., 1oz. on each leg, would be ample for $\frac{3}{16}$ by 1in. cores.—Zinci Sulphas.

[57214.]—**Electric Bell.**—Depends upon the distance of the push from the bell. If for ordinary use, as in a house, six turns on each bobbin will work with one No. 2 cell.—C. D. R.

[57214.]—**Electric Bell.**—Replying to "Constant Reader," I am afraid he will find his magnet too weak to do the required work, being only $\frac{3}{16}$in. diam. I use ⅜in. and $\frac{7}{16}$in. diam. cores for the same size gong. Three layers on each core of No. 26 c.c. copper wire will suffice.—J. Kean, Northampton.

[57215.]—**Experimental Pottery Furnace.**—A full description of such a one was given early last year in the *Photographic News*, under the head of "Ceramic Photographs."—S. Bottone.

[57220.]—**Batteries.**—You must be guided by the experiment you wish to perform. What are you going to use them for? Whose cells are they, and what form? Gravity cells should be used only for testing, &c. If you have procured them for any other purpose you have wasted your money.—C. D. R.

[57222.] — **Lecture Illustrations.** — 1. Yes. 2. A good three-wick paraffin lantern, on the Sciopticon principle, with 4in. condensers. 3. Yes; admirably.—S. Bottone.

[57223.]—**Chemical Action in Battery.**—In a battery of zinc and carbon with chloride of ammonia, the chemical action is as follows:—The zinc unites with the Cl of the ammonium chloride and sets free hydrogen and ammonia. This latter at first dissolves, but is afterwards given off as a gas, thus:

$$Zn + 2ClNH_4 = ZnCl_2 + {}_2NH_3 + H_2.$$

In a battery of zinc in a solution of ammonic-chloride ($NH_4Cl$), and a carbon rod in a porous cell, packed with oxide of manganese, the chemical action is somewhat different. Chloride of zinc is formed by the action of the Zn on the $NH_4Cl$, the separated ammonium immediately decomposes into hydrogen and ammonia, the latter of which at first dissolves in the solution, but escapes as a gas when this is saturated. The hydrogen, meanwhile, after causing successive decompositions of contiguous molecules of chloride of ammonium, appears through the porous cell and finds itself at last in contact with the manganese oxide; this oxidises the hydrogen to water, being in the first instance reduced to sesquioxide, according to the equation:

$$Zn + {}_2ClNH_4 + MnO_2 = ZnCl_2 + 2NH_3 + H_2O + Mn_2O_3.$$

The ultimate condition of the manganese oxide is not known.—J. Kean, Northampton.

[57224.]—**Prevention of Noise.**—I should make a wooden tray to hold 2in. or 3in. of sawdust, and place the lathe standard on pieces of board which rested on top of said sawdust; but these pieces must not touch any part of the tray itself.—A., Liverpool.

[57224.]—**Prevention of Noise.**—Put ½in. thickness of sheet rubber under each foot of the lathe, and put a thick rubber washer under the head of each bolt or screw used to fasten the lathe down to the floor, and the nuisance will cease. I have done this with a smith's anvil on a floor over a sitting room, and used the anvil constantly without any nuisance for years.—T. F.

[57224.]—**Prevention of Noise.**—If convenient take up the boards and put sawdust under the place where lathe stands. If this is not convenient, place the lathe upon two pieces of wood, with several thicknesses of stout felt under them; screw the wood to the floor. A thick piece of old carpet under all would also help. The wood floor must be covered to prevent vibration.—F. M. Bear.

[57229.]—**Gold and the Mint.**—There are dozens of respectable silversmiths and melters in London and Birmingham to whom you can send your gold and have the full value returned without any risk. Have you no local man?—C. D. R.

[57230.]—**Cardew's Voltmeter.**—This voltmeter should be connected as a shunt to the circuit, and it will then measure the difference of potentials at the point where it is connected; a table of the values of the readings in volts is supplied with the instrument. A push or switch is generally used, so that the voltmeter may only be connected when the reading is taken.—Eugene Brown.

[57231.]—**A Six-footed Pig.**—Not worth keeping, but if you intend doing so you can preserve them in spirits of wine in a glass bottle hermetically sealed.—C. D. R.

[57232.]—**Heating by Steam.**—"A. D." can heat his building from his boiler quite easy with steam, but he cannot put the condensed steam back into the boiler—that is impossible; but he can put back the steam again after condensation has ceased, and it will work away without attention with from 10lb. of steam upwards. I would not advise him to put the exhaust steam through, as it would choke his engine. I fitted up a worsted mill from the boiler and it works splendidly, and is not the least troublesome; so if "A. D." gives me his address in the Address column I shall treat with him.—Busby.

[57235.]—**Thermometer.**—Yes; a well-constructed thermopile in connection with a galvanometer.—S. Bottone.

[57236.]—**Paste.**—I find that a little borax, in powder, put into the paste during the process of making it has the property of preserving it as solid and good, although it be kept in an open jam jar for over a month, as it was on the day it was made. I also sometimes, for certain purposes, mix a little glue with it after having made it, which seems to increase its sticking powers.—A., Liverpool.

[57238.]—**Vacuum Tube Rotator.**—I know of an instrument which would suit "W. P. W.," but it would be very troublesome to describe, and would take much space; but if "W. P. W." will advertise his address in this paper I will communicate with him.—Accumulator.

[57239.]—**Coil Regulator.**—This has been described several times. See No. 1,042, page 40, Reply 56033.—C. D. R.

[57239.]—**Coil Regulator.**—If "W. P. W." wants to thoroughly upset his nervous system for a few days let him take the shock from a ¼in. spark coil. He had better make a new coil entirely for shocks and leave the ¼in. spark as it is. He will find plenty of instructions in back numbers.—Zinci Sulphas.

[57240.]—**Automatic Musical Instruments**—As a sequence to my articles in this journal for August 1st, 8th, and 22nd, 1884, "On the Production of Tune Bands for Automatic Musical Instruments," some explanation has been called for of the kind of instrument for which these music bands are adapted. As a description of mechanism, taken in a scientific sense, this is proper enough. The tone of the cross-examination that "B." subjects me to is more personal than practical; still, there is no reason why I should not reply. He first asks, "Is it practically successful?" Quite so; as may be judged from the simplicity of its construction; it is a machine that will not wear, or get out of order by long use, and as by the control of quality of touch given by the striker or finger piece, and the command of expression, the performance was found to be in advance of anything that had before been done in the way of a mechanical piano player. I secured it by patent, though my original object was to construct a machine for performing on the piano for my own use only, as a slight accident to my left hand had ever prevented me from doing this. I did not exhibit at the "Inventions" because I had no desire to engage in a business of this sort, or be involved in any way before I had fully satisfied myself as to the market prospects or demand that make it worth while as a manufacturing undertaking; therefore, it did not suit my purpose to part with the only instrument that I then possessed, and also provide a piano, and an attendant to perform upon it during the brief time allotted each day (no special demonstrations being allowed by the rules), so I did not feel inclined to be at any trouble for the sake of picking up orders that could not be executed. Having now a considerable stock of music in bands, I frequently use the machine and display its performance to my friends or experts. Nor (as may be judged by my communications) do I wish to throw any difficulty in the way of constructive amateurs desirous of trying their skill in this direction; but I cannot engage to play to persons not introduced, who may desire to listen to music only out of mere curiosity. If "B." has any particular object in mind in which I can aid him, will he kindly write to me or advertise his address in these columns?—F. H. Wenham.

[57242.]—**Portland Cement.**—There is an account of this substance in Wagner's "Chemical Technology," which will, I think, suit the querist.—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[57244.]—**Dentistry.**—I will send "Mechanic" working drawing of vulcaniser, and, if he wishes to take a course of lessons, refer him to Address column.—Dentist.

[57244.]—**Dentistry.**—As a dentist has to deal with the living subject, there can be no toleration for such a thing as an amateur dentist, and if "Mechanic" wants to go in for dentistry he had better begin by serving a regular apprenticeship.—Dens.

[57244.]—**Dentistry.**—It is not possible for anyone to become proficient in the art of dentistry unless they serve time to a good master; then it takes several years before they are able to do anything more than a repair. Dentistry is so complicated that I should advise "Mechanic" not to attempt anything of the kind. I have been at dentistry about nine years, and if "Mechanic" likes to advertise his address in the English Mechanic, I should be happy to see him.—Vincent.

[57249.]—**Electromotor Reversing.**—Beyond the strain caused by the sudden stoppage, no harm would accrue.—S. Bottone.

[57251.]—**Agglomerate Blocks.**—I should say the blocks were not as they should be? Whose make are they? There are quantities of so-called agglomerates that have not a particle of manganese in them. Use the Indiarubber Co.'s, who are the patentees, and you will have no cause to complain. Why do you not charge with sal-ammoniac? It gives much better results.—C. D. R.

[57252.]—**Free Reeds.**—(1) Professional tuners nearly always omit the octaves until the bearings are laid, tuning by fifths upwards and fourths downwards, the fifths a shade flat, the fourths by a like amount. (2) The exact speed of beat is of course regulated by the absolute pitch at which the reeds are being tuned. For C' 264 vibrations per second the beats of the fifths are as follows:—

| | | | | | |
|---|---|---|---|---|---|
| C'' | to | g' | 53·4 | beats per minute | 1 |
| C sharp | ,, | g' sharp | 57· | ,, ,, ,, | 8 |
| d' | ,, | a'' | 60 3 | ,, ,, ,, | 3 |
| E' flat | ,, | B' flat | 64·2 | ,, ,, ,, | 13 |
| E' | ,, | b' | 67·5 | ,, ,, ,, | 5 |
| F' | ,, | A'' | 71·6 | ,, ,, ,, | 11 |
| F' sharp | ,, | C'' sharp | 75·6 | ,, ,, ,, | 7 |
| G' | ,, | D' | 80 4 | ,, ,, ,, | 2 |
| A' flat | ,, | E'' flat | 85·2 | ,, ,, ,, | 9 |
| A' | ,, | E'' | 90· | ,, ,, ,, | 4 |
| B' flat | ,, | F'' | 95·4 | ,, ,, ,, | 12 |
| B' | ,, | F'' sharp | 101·4 | ,, ,, ,, | 6 |
| C | | | | | 10 |

The figures in the last column give the order in which the notes in the first column are generally tuned. This plan keeps the bearings in the middle octave. For fuller particulars see Staines and Barrett's dictionary on "Temperament," or Broadhouse's "Student's Helmholtz," or Dr. Stone's "Scientific Basis of Music." For general purposes, from one beat per second to three beats in two seconds for flat fifths is quite near enough, such a thing as perfectly equal temperament being unknown except in theory. (3) Tune reeds in the instrument on a medium pressure, and go over the bearings again carefully the next day if possible before tuning the octaves.—A. B. C.

[57252.]—**Free Reeds.**—I am pleased to learn that "Amateur Tuner" has now definitely stated what he requires to know. I should be obliged to the querist if he would kindly state if he is not the author of the queries Nos. 56400 and 56676, although the signatures at the bottom differ? I ask on behalf of our professional friend, "G. L. B.," who seems reluctant to inform "Amateur Tuner" how to make a tuning apparatus, which has now been asked for. I will, however, reply to the questions asked in the above query. 1. It is not customary to tune by "fifths" only, and all octaves should be tuned perfect, which means without the least perceptible wave. 2. The "speed" of the waves, in the various intervals of the scale, varies. The most important, and at the same time most difficult, task in the art of tuning is in making a good "equally tempered" scale. To do this well requires considerable practice and experience, and also a good ear. The querist would do well to practice pianoforte tuning as well as reed tuning. I should advise him to procure "Hamilton's Art of Tuning," or any other textbook, which will give him all the theoretical knowledge he requires. Then, with plenty of practice, he may succeed. Little can be done to assist the querist by way of writing. 3. Tune the reeds under the same pressure as that to which they will be subjected when placed in the instrument in which the reeds are intended to remain. 4. I cannot answer the last question until I know under what conditions the reeds are sounded when out of the instrument. The question is, Does the pressure of air vary under the two different circumstances in which the reeds are set in vibration? A reed may be made to sound a trifle flat under various circumstances.—G. Fryer.

[57255.]—**Storage Battery.**—The size accumulator you purpose constructing is useless except for lighting small microscopic lamps. How do you propose to charge it? Read the article on page 28, No. 1,016, Sept. 12, 1884.—C. D. R.

[57257.]—**Equatoreal Mounting.**—Replying to your inquiry in this week's "E. M.," if you are in town, and care to call on me at 47, Botolph-lane, E.C., I can give you just the information you require, the result of some months' practical experience. I can also give you, with pleasure, the top of a stand I manufactured for equatoreally mounting a 3in. refractor (now discarded in place of a 6in. reflector). The appliances are in Dulwich. This would be very useful provided you only wanted to follow stars. If you want to find them, the matter is more difficult. For this purpose I have an instrument I bought of Negretti and Zambra for £3. I should be glad to sell, and some home-made ones to give; but this is not my object in writing. Having gone over the ground myself, with no one to teach me, I think I can help you considerably, and I should be delighted to part with the rough but useful appliances to anyone to whom they would be of service.—Fred. Wright.

[57258.]—**Chemical.**—"Organic Chemist" should get the very latest edition of G. Jarmain's "Systematic Course of Qualitative Chemical Analysis," price 1s. 6d. (Longmans and Co.), in which he will find tests and reliable tabular methods for the detection and separation of the organic acids he names.—W. Scudamore.

## UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

Since our last, "Experimenter" has replied to 56649; "Zinci Sulphas," 56768; W. J. Grey, 56790.

**The Asylum "Tell-Tale."**—This "Tell-tale," devised by Dr. J. Millar, L.R.C.P. Ed., Medical Superintendent, Bethnall House Asylum, and exhibited at the Inventions, Stand 2100, consists of a clock movement so arranged that the hour axle carries a paper disc instead of the usual hand. It is inclosed loosely in a strong mahogany locked box, which may be fixed anywhere and in any position. In the lid of the box a hole is bored sufficiently large to admit of the insertion of a pencil. The night attendant in passing a station merely inserts the pencil gently as far as it will go, and gives it a twist so as to insure a mark being made on the paper disc, which has been set so that it corresponds with the time a mark is made. On inspection in the morning, when the clock requires to be wound up, a record will be found on the paper of the time of each visit. To save changing the paper oftener than once a week, three differently-coloured pencils are used—a different one each night. By this means three nights will be recorded in the outer ring of the disc. As the colours are different there is no difficulty in recognising the marks. To bring other rings into use the clock is raised by one or two of the slips of wood provided, and upon these circles two nights each may be recorded, thus completing the week, when the disc should be removed and another substituted, recording upon it the station and date. The simplicity, economy, and efficiency of the arrangement have been proved by fifteen being in regular use at the Asylum, Bethnal-green, for more than six months, without a hitch. More than 100 are now in use in various asylums in England.

# QUERIES.

[57272.]—**Dynamos for Practical Purposes.**—I wish to make a dynamo for working a Griscom's motor, a small electric mallet, and a 2½ c.p. lamp for about five hours daily. Will some of your readers kindly tell me what form of small dynamo is the best for such work, and what power I should require for such a machine? Should I require secondary batteries or not?—F. H. Briggs.

[57273.]—**Radius of Curve.**—Would some reader kindly give the method of finding the length of radius in the annexed formula for calculating the ordinates of a circular arc:—

E F = ordinate
R = radius
V = versed sine
D E = distance from centre to any ordinate

$$EF = \sqrt{(R - DE)\,(R + DE)} - (R - V).$$

The case in point is to set out the camber on an iron girder, 70ft. span, with a rise of 7½in. in centre, the ordinates every 2ft. If there is any simpler mode of finding the ordinates, and setting out the curve, the formula will oblige.—Fred. Street.

[57274.]—**Organ Pedals.**—Will any reader of the Mechanic, or amateur organ builder, kindly inform me whether there is an exact gauge for organ pedals, lately decided upon by any musical authority? I am about to construct a radiated pedal board, and will thank anyone for exact dimensions required for a set of pedals, 30 notes CCC to F?—Pedlier.

[57275.]—**King's College Dynamo.**—I should be much obliged if any student in the engineering department at K. C., or anyone connected with the same, would tell me the sizes and quantities of wire required for winding the dynamos that are made by the students there; also how the commutator gear is arranged, and its candle power? I believe there is only one size.—G. Park.

[57276.]—**Experiments in Light.**—Would any of your correspondents kindly inform me what kind of lantern would be most suitable for illustrating the experiments in light, required by the Science and Art Department? Must be cheap, portable and effective.—R. R. R.

[57277.]—**Science and Art Department.**—To Wm. J. Grey.—The question having been asked in the House of Commons "whether the standard in these examinations had been raised," and a reply given in the negative, it would be interesting to me, and probably to others, to have different views on this subject. I therefore venture to ask W. J. Grey and others, to give me their opinion on the matter, and especially on the advanced theoretical chemistry, and the elucidation of questions 11 and 12 of elementary stage.—R. R. R.

[57278.]—**Recovering Silver.**—Would Mr. Lancaster, or any other correspondent on photographic subjects, kindly tell me how to recover the silver from an old nitrate of silver bath? About how much per cent. is wasted; also if it is worth the while? How to recover it from silver print clippings; and also the platinum from the clippings of platinotype paper? I may mention that I have the use of a wind furnace capable of melting steel.—G. Park.

[57279.]—**Planing.**—I am told a lathe bed can't be planed as well by hand as by steam—why?—F. Shakespear, Dresden.

[57280.]—**Spring Bell for Till.**—Would any fellow-reader kindly inform me how I can make a small bell to ring when a drawer is pulled out, about the sound of a tram conductor's punch? The bell to be hidden in the till somewhere, out of fear of molestation, the till to be screwed on top of a cupboard. Any hints will greatly oblige.—Fogeye.

[57281.]—**Queen's Taxes.**—Can Queen's Taxes be distrained for elsewhere than on the premises? Say I leave a house at October, with the taxes unpaid, can I be followed to another part of the parish, and distraint made there ten months after leaving, or is the landlord liable? And how about other taxes under the same conditions—poor rates, &c., I mean?—Victimised One.

[57282.]—**Watch Work.**—Will "Escapement," or some kind reader, inform me what tools are used to turn and cut the pivots on watch pinions? A list of the best kind, and about their cost, will oblige a five years' subscriber.—B. L.

[57283.]—**Cold Air Machinery.**—I want to produce cold air on a small scale for cooling purposes, in place of using ice. Will any of your readers who have any knowledge of the matter kindly inform me if it is practicable to produce on a small scale, a current of air cooled to about freezing point, and if there are any makers of machines for that purpose?—Transit.

[57284.]—**Copper Coating Boiler.**—Will some reader of "Ours" kindly give me some instructions? I want to coat with copper the inside of a washhouse boiler; it has slightly rusted, and clothes boiled in it are stained, causing a lot of extra labour. Could I clean it with dilute nitric, fill up with sulphate of copper solution, and then, using larger copper anode, deposit electrically? I find generally that coppering iron is not permanent, it appears to eat away the iron, and fill the space with copper; but it soon peels off. I cannot move the boiler, as it is built in brickwork.—One in a Fix.

[57285.]—**Focus of Lens.**—I am making a reflecting galvanometer, and wish to use a flat mirror and fix the lens (in a sliding tube) to the galvanometer bobbin, but do not know of any formula for determining the focus of such a lens. If any reader could give me an equation, he would greatly oblige.—Lens.

[57286.]—**Bed Sores.**—The patient, a middle-aged man has for some weeks been greatly troubled with bed sores. Suffering from hip-joint disease, he has been compelled to lie on his back for the last twenty weeks, the pain being so acute as to prevent his being moved, other than raising him a few inches while the bed sores are being dressed. The pain is frequently so great, that at times he cannot bear the weight of a sheet upon his legs and thighs, and dressing the sores is almost out of question. Would some hospital, workhouse, or any other experienced nurse kindly advise what is the best to do to give relief in such a case? The patient is laid upon a water-bed; the sores have been dressed with white of egg, starch, Fuller's earth, Fuller's earth and glycerine, and sanitary rose powder. In the case of the powders, they have been applied dry, without anything, but principally upon French oiled silk, covered with lint, strapped on with soap plaster, and finally covered with cotton-wool. Also please to say if anything better can be used than soap plaster for strapping on the lint, &c., the excessive stickiness of this plaster causing pain, and often a sore on removal? Advice is asked only from those who have experience in such cases, as this is a most unusual and serious case.—W. S. L.

[57287.]—**Angular Aperture of Micro. Objective.**—How can I tell the angular aperture of a micro objective, and what advantage results from the use of a large angle in objectives of equal focal length?—C.

[57288.]—**Machine for Tearing Rags.**—Would some kind correspondent help me out of my difficulty? I want to construct a strong but cheap machine for tearing up woollen rags, to be used afterwards for manure. I have a small water-wheel, about six horse-power, available to work the same. If someone would describe clearly a suitable machine, and give a rough sketch, and state the power required to work the same, he would greatly oblige.—A Farmer.

[57289.]—**Electric Lighting in Mines.**—We read that the great objection to the use of the electric light in dangerous mines is the liability to sparking and the consequent explosion of the firedamp. What is meant by the sparking in this case? Does it mean the sparks which are produced when the wires are being coupled up to the lamps, or uncoupled, or does it mean the sparks which are liable to be produced by the accidental breaking of the conducting wire?—Ex-Garrison Gunner.

[57290.]—**Woolwich Exam. Question.**—In the entrance exam. paper for June, 1884, there is an arithmetical question, which neither my son, who is a R.E., nor myself, a C.E., can solve satisfactorily, so that it is worthy of the "steel" of some of the readers of the "E. M.":—

Given log. 3 = ·4771213
log. 7 = ·845098
log. 3·6593 = ·563399
To find the log. of 11.

The last number 3·6593 is the cube root of 49, so that it could have been found from log. 7, which is given; hence the log. of this number must be given, I presume, as a clue to the solution. I can find the answer correct to about three places of decimals, but I suppose we are to find it correct to at least five places.—M.I.C.E., Bath.

[57291.]—**Weights of Copper Wire.**—Can any of our electrical friends inform me the weights per mile of the following wires (single and strands) by the new standard wire gauge, also the size in mm., and where I can obtain a good book on the subject, and whether there are any gauges made which contain the mm. decimals to an inch, and the number of the wire all combined in one, and also where obtained? I have got a standard wire gauge; it is from No. 1 to 26, but no mm. or decimals on it:—

| Single wires. | 7 Strands. | 14 strands. | 19 strands. |
|---|---|---|---|
| 1 | 7/1 | | |
| 2 | 7/2 | | |
| 3 | 7/3 | | |
| 4 | 7/4 | | |
| 5 | 7/5 | | |
| 6 | 7/6 | | |
| 7 | 7/7 | | |
| 8 | 7/8 | | |
| 9 | 7/9 | | |
| 10 | 7/10 | | |
| 11 | 7/11 | | |
| 12 | 7/12 | | |
| 13 | 7/13 | | |
| 14 | 7/14 | | |
| 15 | 7/15 | | |
| 16 | 7/16 | | |
| 17 | 7/17 | | |
| 18 | 7/18 | | |
| 19 | 7/19 | | |
| 20 | 7/20 | | |
| 21 | 7/21 | | |
| 22 | 7/22 | | |
| 23 | 7/23 | | |
| 24 | 7/24 | | |
| 25 | 7/26 | | |
| 26 | | | |
| 28 | | | |
| 30 | | | |
| 34 | | | |
| 39 | | | |

(14 and 19 strands the same as 7 strands.)

—Young Electrician.

[57292.]—**Ebony.**—I have made a book case, and want to finish it so as to look like ebony. I have given it several coats of paint, but find that it leaves it too rough, so now I have used pumice and made it smooth, but cannot get on further. Cannot I get a kind of enamel, like Judson's Artist's Black, only much cheaper, for it would take about 12 bottles like their 1s. size? I cannot stain it, for it has on the paint.—Vincent.

[57293.]—**Razor Grinding.**—Will some kind reader of the "E.M." inform me the practical way of grinding razors and scissors ready for use, as I am about to start in that line?—D. G.

[57294.]—**Haydon's Cutter Bar.**—I have made one of the above from instructions lately given in "Ours." Will the writer, or others, kindly explain the simplest way to grind the cutter, as I don't quite understand the shape of the point? Should cutter be made of piece of square steel, and is it ground while in the bar?—A sketch would oblige.—Surveyor.

[57295.]—**Bookbinding.**—What is the reason the backs of my books are not firm, and do not retain their round shape after blocking? The first time book is opened, the back goes quite flat, and edges on the twist, although I leave in press till glue is dry. Practical hints about blocking and cutting will oblige.—Surveyor.

[57296.]—**Surveying Chain.**—Should these chains be exactly 66ft. long, or is it usual to make them rather longer, so as to allow for them not always being pulled quite straight and tight? I have tried mine by a new tape, and find my old one a link too long. A nearly new chain which I have, I find is quite two links too long, and yet only has 98 links, the 10 marks being only 9 links from either end. The old chain has exactly 100 links. Hints as to testing chains from a practical man will be much appreciated.—Surveyor.

[57297.]—**Boiler.**—The boiler to the engine which I attend is fed by an injector, which acts in a very irregular way. I cannot use it at all under 40lb. pressure. Sometimes having to attend to other duties, the water during my absence will get low in the gauge; the steam likewise has gone down. Before I can put any water into the boiler, I have to fire up, and get up steam. Is the fault in the steam nozzle or water delivery? The highest pressure the Insurance Co. allows is 60lb. The boiler is externally fired, 2ft. 10in. diameter, and the water-feed is carried in from the top to 8in. from the bottom of the boiler.—W. S.

[57298.]—**Faulty Dynamo.**—To Mr. Bottone or Others.—I have been trying to make a small dynamo, from the instructions given in "The Dynamo," but find that it will not answer at all. On sending a current from a battery through the F.M.'s, I obtained shocks like those of an induction coil, and on revolving the A. got a very feeble current; without the battery it will give no current at all. The F.M.'s are only very slightly magnetised by a single bichromate; but their continuity and insulation seems to be perfect when tested with the galvanometer.—Disappointed.

[57299.]—**Steel Castings.**—I should esteem it a great favour if any of your steel and malleable iron-smelting correspondents could instruct me how to mix the metals for making steel castings, light and heavy work, and also the proportions of the metals used? Are there any chemicals used in the process, and the names and proportions, and how to use them?—H. K. B.

[57300.]—**To "Invicta."**—Many thanks for answering my query, No. 57109. I have got my 3in. achro. of 50in. focus, and should like to write you a few letters as to the mounting and making up of eyepieces. I know your time must be very limited, owing to the numerous correspondents you have through this journal; and I would not trouble you, but for this reason: That I am off to Australia in two months' time.—Focus.

[57301.]—**Shaft.**—On a shaft 12in. diameter there is keyed a wheel 12ft. diameter, which gears into a pinion 26in. diameter. What diameter must the shaft for the 26in. pinion be? Also what work on the strength of material would they recommend?—Lil.

[57302.]—**Scraping Metal.**—Will some reader kindly inform me why in scraping hollow in o.g. moulding (metal), I make it ridges, instead of straight, smooth surface. I think the scaper is a right one, being made by grinding half-round file.—H. H.

[57303.]—**Electric Motor.**—Will S. Bottone or "W. H. E." kindly help me in the following: I have a Crompton compound-wound dynamo giving 110 volts, and about 30 ampères. Now I wish to connect to above (which already works incandescent lamps in parallel) an electric motor of about one-man power. Will any of above give me directions as to winding?—Electra.

[57304.]—**Electric Bells.**—I want to connect an electric bell (single stroke) to an electric-light circuit, E.M.F. being 120 volts, and total C. about 40 amps. The dynamo working incandescent lamp. What res. must I give bobbins on bell? Distance over which they will have to work will be 20yds.?—Electra.

[57305.]—**Bronze.**—Will any of "ours" kindly give me a good recipe for above of a brownish colour? I wish to colour a few pieces of brass with it?—Electra.

[57306.]—**Dynamo.**—Would S. Bottone or others kindly give dimensions of armature for following machine: F.M. similar to Brush; eight coils (four each side), each coil about 250ft. No. 11 cotton covered. Faces of pole pieces about 10¾ dia. and space between for armature 2¼in. Present armature 8 coils No. 16 cot. cov., but perfectly useless, being wound anyhow. Wanted for incandescent lamps either series or multiple arc. Would plain iron wire core (Pacinotti form) do best, or what?—Incandescent.

[57307.]—**Microscopical Eyepieces.**—How can I find out the magnifying power of the eyepieces to my microscope? Would an optician be able to tell me?—Micro.

[57308.]—**Water Microscopes.**—"The Ghost of Stephen Gray" would confer a favour upon subscribers of "E.M." by giving a more detailed description of the above when next he pays a visit to the pale glimpses of the moon.—R. M.

[57309.]—**Algebraical.**—A vessel just contains a pint of wine; a pint of water is now poured gently into the vessel. Supposing the water to mix completely with the wine as the process goes on, how much wine will be left in the vessel after all the water is poured in?—B. H. B.

[57310.]—**Wheatstone Bridge.**—Will some reader of the "E.M." kindly inform me where I can find stated, or tell me, the best arrangement of "arms" to use when measuring resistances by this method—that is to say, which are the best arms—10 and 10, 100 and 10, 1,000 and 100, or what—to use when measuring high and low resistances respectively? Also, for what resistances (approximately) should a high resistance galv. be used, and for what resistance a low-resistance galvanometer?—M. C. G.

[57311.]—**Flour.**—The flour I buy is good in gluten, which is what I esteem; but in eating there is a grittiness. I have found sand in my pepper, which reminded me of the old saying forcibly—viz., "when you have sanded the sugar, and damped the tobacco, come up to prayers, Maria." But I hardly think this is the case with my flour. I wish to know what it is, and method of judging good flour for gluten, and to detect adulterations.—P. W. R.

[57312.]—**Truing Lathe.**—To "Invicta" or Others.—I have a 5in. screw-cutting lathe (Whitworth's pattern). Can you kindly explain how to set lathe-head true to saddle for cross-surfacing.—P. W.

[57313.]—**Steam Launch.**—To "INVICTA" OR OTHERS.—I have a 3in. bore by 3in. stroke direct-acting steam-engine. Can you kindly state what size boat, and at what rate, it will propel it with four or five persons in it? Also, what size boiler and propeller it will require? —P. W.

[57314.]—**Electrical.**—Will Mr. Sprague or some other electrician please explain the paragraph in Gray's "Absolute Measurements in Electricity and Magnetism," referring to Thomson's method of measuring low resistances? The paragraph runs thus:—"The sections A D are so far from the ends of the rods . . . by a small fraction of the actual resistance of the wire in each case." Chap. IX. pp. 98, 99 (referring to Fig. 12). Is not the current always parallel to the axis? And if not, how can fastening the wires at some distance from the end of the rod, and making A M D and B C L of certain resistances, have any effect? Also, what is meant by "The effect of any resistance of contact . . . the wire in each case"? —M. C. G.

[57315.] — **Botanical.** — What kind of paper do botanists usually use for mounting their dried botanical specimens, and what is the price of such paper? Is there any cheap glossary of botanical terms published, and, if so, what is its title, and author's name?—B.

[57316.]—**Turbine Wheel.**—Would any reader of this journal be good enough to say, through these pages, whose turbine water-wheel is the best at present in use; and what size of a wheel would best suit a 9ft. fall with 2,000ft. of water passing per minute, and how many horse-power the fall and quantity of water would give?—JAMES.

[57317.]—**Scarlet Fever.**—I should be glad to know if it is generally believed that the infection of scarlet fever can be conveyed in milk. What is the best mode of disinfecting a room, bedding, and clothes used by a scarlet-fever patient?—RUFFLER.

[57318.]—**Lippmann's Ampere-meter.**—I was much interested in your description of the above ingenious instrument, and should be glad of further particulars respecting it, as it accomplishes the object sought in a manner which has been long attempted—but hitherto in vain—by electricians, namely, that between the parts acted upon by the forces to be measured there should be no relative movement either of translation or rotation. This is accomplished most ingeniously in the instrument described, for the small element carrying the current to be measured always occupies the same position in the magnetic field. I should be glad if any fellow reader can give further information about it, as I am sure it would be interesting to others as well as—A. D. RAINE.

[57319.]—**Electro Magnet.**—Some time since I made an electro-magnet by winding two bobbins, 4in. long by 2½in. wide, full of No. 14 wire (4lb. wire exactly filled the two), core 1in. in diameter. What I wish to know is whether I can use the same for the fields of a dynamo to light when finished about 4 × 6 candle lamps. Could Mr. Bottone or W. H. Eaves give me the size and quantity of wire to wind on armature, proper size of pole pieces, &c. If I unwind wire I shall probably be unable to rewind it, as I have two coats of shellac varnish on each layer.—ZINCI SULPHAS.

## USEFUL AND SCIENTIFIC NOTES.

**Number of Nails in a Pound.**—The following table shows the number of nails of the various sizes contained in a pound: 2d fine, 1,000; 3d fine, 760; 3d common, 480; 4d com., 288; 5d com., 200; 6d com., 168; 7d com., 124; 8d com., 88; 9d com., 70; 10d com., 58; 12d com., 44; 16d com., 34; 20d com., 23; 30d com., 18; 40d com., 14; 50d com., 10; 60d com., 8. The length of each nail mentioned is as follows: 2d, 1in.; 3d, 1¼; 4d, 1½; 5d, 1¾; 6d, 2; 7d, 2¼; 8d, 2½; 9d, 2¾; 10d, 3; 12d, 3¼; 16d, 3½; 20d, 4; 30d, 4½; 50d, 5½; 60d, 6in.

**A New Test for Codeine**—M. Lafon has found a characteristic test for codeine. A minute quantity, even a fraction of a milligramme of codeine, imparts a splendid green colour to a solution of one gramme of selenite of ammonium in twenty cubic centimetres of strong sulphuric acid. It appears that morphia is the only known alkaloid that gives anything like the same reaction. When selenium is dissolved in strong sulphuric acid, the green colour is the result; and codeine is said to have the power of setting selenium free from the ammonic salt.

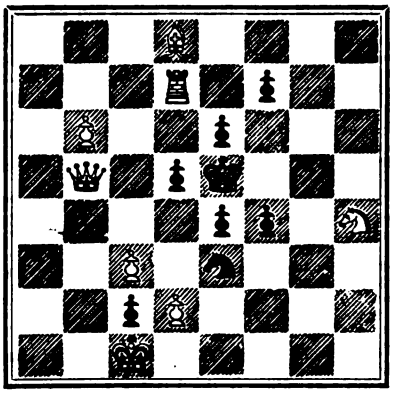
**Painter's Oils.**—The longer oil is kept the better, both as regards drying and transparent qualities. To make good nut oil, the skins of ripe walnuts should be peeled off, as it contains an acid which turns it brown. Poppy oil is made from the ripe seed of poppies. It is the best drying oil. The oil of spike, or lavender, is obtained by distilling spike with water; it is very volatile and fine for working with the pencil, or for enamelling. To make a good drying oil for extra-fine painting, take of poppy oil or nut oil one pint, of gum sandarac two ounces, of white vitriol and sugar of lead each one ounce. Boil the whole till the solid ingredients are dissolved, and the mixture is the colour of linseed oil. This oil will dry fast, and a portion of turpentine added makes a fine oil for use when the purest white tint is required. It may be mixed with other oils as a drying, where common drying oil would be injurious to the colour. Raw linseed oil for woodwork is best, as, being more volatile than boiled oil, it strikes into the wood and forms a hard, resinous filling.

## CHESS.

ALL Communications for this department must be addressed to J. PIERCE, Langley House, Dorking.

PROBLEM DCCCCLIII—RESPICE FINEM.

*Black.*



*White.* [8+8

White to play and mate in two moves.

SOLUTION TO 951.

| *White.* | *Black.* |
|---|---|
| 1. Kt-Q B 4 | 1. Anything |
| 2. Q or Kt mates. | |

(Five variations.)

### NOTICES TO CORRESPONDENTS.

CORRECT solutions to 950 by J. A. Miles (very good problem). That by E. Stanley Follwell is wrong, as Black's second move puts W K in check.

To 951 by E. Stanley Follwell, J. A. Miles (good), F. O'N. H., A. A. R., Lecluse (a splendid problem), Rev. W. Anderson (Old Romney), and W. D. Porter.

To 952 by Streetgate and E. S. (but second variation incomplete).

R. G. BROTHERO.—For a problem to be sound there should be only one solution possible from the first move. Black may have several defences; to each defence there should be but one way of mating, though the play on both sides in all the variations may be different. If in any variation there should be more than one way of mating this is considered a blemish, more or less serious according to the importance of the variation; as in several of your "sixteen variations" to 947, White's second move is exactly the same, the number is reduced to six.

J. RUSSELL.—Thanks for game.

As the Second Game Correspondence Tourney is very nearly concluded, we propose starting a third on different lines, as likely to be more acceptable than the preceding, although both the first and second Tourneys have been highly successful, and produced some excellent games. We think, instead of having three or four prizes obtained from the subscriptions, it would be much better to divide the amount according to the number of games won by each competitor. Thus: Supposing there are twelve players, and any given player (A) wins seven and loses four games, he would receive three times the stake on each game. If he lose seven and win four, he would have to pay that amount. We think also it would be fairer for each to play two games (simultaneously) with his opponent, so as to neutralise the advantage of first move. We shall be glad to receive the names of any who would like to join. We have already two; the number would be limited to sixteen. The stake on each game might be fixed at half a crown.

**Zinc Sheathing for Ships.**—The Chilian ironclad *Blanco Encalada* was docked the other day at Hebburn-on-Tyne. Much interest was attached to the circumstance on account of the ship not having been docked since she left England more than ten years ago. The iron bottom of the hull had then been covered with teak plank, fastened with iron fastenings, and sheathed with zinc sheets, in the hope that this arrangement would keep the underwater part of the ship fairly clean and free from decay. The *Blanco Encalada* was visited at Hebburn by Sir Edward Reed, M.P., under whose care she was originally built, and is now being refitted and re-armed, and with him was Admiral Latorre, Captain Montt, who now commands the ship; Mr. W. H. White, of the firm of Sir William Armstrong and Co.; Mr. Leslie, representative of Messrs. Penn, the engineers, and numerous other persons. It is worthy of record that the bottom was found remarkably clean notwithstanding its 10 years' immersion, and that the waste of the zinc sheathing was scarcely as much as had been anticipated. No evidence of any injury to the iron plating of the ship's bottom, which was examined in places, could be detected. The experiment of the zinc sheathing upon a single layer of wood was thus found to have been even more successful than could have been hoped.

## ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* [illegible] *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

### HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Aug. 19th, and unacknowledged elsewhere :—

C. H. DAVIE.—Ezekiel Mundy.—Barnett and [illegible]—S. E. Cottam and Son.—W. Robertson and Co.—Ion.—W. Watson and Co.—T. Elderkin.—A Fellow of the Royal Astronomical Society.—J. Sutcliffe.—Eugene Brown.—E. R. P.—H. D.—Lt.-Col. Ross.—Sandrat.—G. Fryer.—S. Bottone.—W. A. Cooper.—Silly Billy.—Prof. R. B. Ball.—Draco.—Rob. Crus.—Aqua.—C. L[illegible]—Pinion D.—R. B.—M. H.—F. W. Gerhard.—Horological Tommy.—Tyro.—Fireclay.—R. B. F.—Ion.—Col. Shakespeare.

ELECTRICIAN. (There is the Society of Telegraph Engineers and Electricians; we do not know of any other.)—F. J. S. (If you consult the indices, you will find several. Perhaps that illustrated on p. 423 will suit.)—CANTON. (We know of nothing better than a good saw for cutting carbon into plates.)—J. H. G. (See previous answer, p. 141, Vol. XL., and the indices generally.)—A. M. (The Guide to the Whitworth Scholarships is published by Chapman and Hall, and can be had from the Secretary of the Science and Art Department, South Kensington. There is a little book published by Abel or John Heywood, Manchester, which gives a great deal of information about them, with useful hints to intending candidates.)—BEACONSFIELD. (We cannot tell whether you want it timed, tuned, or tinned. The word is written timed or tuned; but presuming you mean tinned, we remember there is a works at Bow. But perhaps Messrs. Hughes, of Drury-lane, would do it for you.)—COAL-GAS. (One is inflammable, the other is not; but there is no simple test for the other.)—C. O. N. (The Legislature of New York simply requires railway companies to fit their stock with automatic couplers. We cannot afford space to give plans and details of the various goods waggons running in the United States.)—J. K. S. (Goodeve's work published by Lockwood and Co., Northcott's by Cassell and Co., and some others; but see the indices, or the publishers' lists. 2. Look through your back numbers for the model boiler you think you can make. There is much on the subject in recent volumes.)—J. J. ALLINGHAM. (By all means, if you can "show a number of new experiments and habits of electricity as would electrify the scientific world," patent them at once, and then describe them. You are, of course, quite sure when you say you "can highly magnetise and demagnetise glass, brass, copper, tin, zinc, lead, and silver," that you do not mean something else.)—INSTRUCTOR. (Apparently you want a set of boring and well-sinking tools. 2. Pictet's ice-making machine is about the best on the small scale. It was illustrated in No. 921.)—ANOTHER AMATEUR. (Mr. T. W. Boord, M.P., 14, Berkeley-square, W., is, or was, the hon. secretary of the Amateur Mechanical Society.)—C. D. (See recent numbers—even last week's, pp. 511, 527. 2. See Mr. Wassell's letters, others now appearing on lens making, and the indices.)—AN OLD READER. (You mean an aged reader, for if you had perused the "E. M." you would know that it is either stain lacquered, or copper bronze mixed in suitable varnish, and painted on.)—ANTI-RUST. (The iron, thoroughly clean, is immersed in a bath of molten zinc, which is covered with sal-ammoniac to prevent oxidation.)—LEDGER. (Of any bookseller.)—WILLIAM TAYLOR. (Where do you find any mention of it? We do not remember the name.)—A LEARNER. (Frequently answered. Look up the indices. Such "works" as there are placed in the hands. 2. The effect is that the coil does not work so well as it otherwise would; but what do you mean by "large"—size of sheets or number? 3. No, we think not; but you can easily experiment. 4. E.M.F. stands for electro-motive force.)—NEWCHURCH. (For cleaning solder, see p. 247, No. 947.)—THOS. BLANDFORD. (No. 740 contains several; but as good a recipe as any possibly is Tartaric acid, 8 parts; carbonate of soda, 4; ground rice, 8. Mix well.)—BALLOON. (The information that you appear to require was given in pp. 20, 44, 71, 95, Vol. XL. Hydrogen will lift more weight than coal-gas.)—ANGUS MAC MUIR. (We cannot go to the expense of making illustrations of engines simply to illustrate queries as to whether they are now running or not, and we think the L.B. and S.C. engine mentioned has been fully described enough without a sketch.)

**Holloway's Ointment.**—Sore[illegible]tions, and other diseases affecting the skin, are capable of speedy amendment by this cooling and healing Ointment, which has called forth the loudest praise from persons who had suffered for years from bad legs, abscesses, and chronic ulcers, after every hope of cure had long passed away.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
*FRIDAY, AUGUST* 28, 1885.

## ELECTRO-METALLURGY.*

TREATISES on electro-metallurgy written in French are not so numerous as those in English and German, although Roseleur's work and Becquerel's "Eléments d'Electro-chimie" take rank on the first line. As M. Fontaine points out, we have in English the works of Sprague, Napier, Watt, Urquhart, Gore, and Wilson, of which Watt's has run through so many editions that it is, we believe, to be superseded by a more elaborate treatise by the same author. As our readers are aware, Mr. Sprague does not deal much with the processes of the factory, but endeavours to give a clear comprehension of the principles underlying them, while the work of Dr. Gore is chiefly valuable as a record of investigations and experiments in electrolysis, some of which are little known and rarely repeated, not to say practised. The other works are more or less practical and trustworthy; but Roseleur's and Becquerel's are, as M. Fontaine says, the complements of one another and—out of date. He has had much experience, and for many years has been intimately connected with many specialists, especially those engaged in nickeling and refining copper, and is therefore justified in supplying what he terms a "lamentable deficiency" in French technological literature. We presume it occurred to Mr. Berly that what would be found useful to a French reader might not prove altogether valueless to English readers, and at all events many of them will thank him for introducing the work to their notice. Quite apart from its commercial applications, electro-metallurgy is a favourite "amusement" amongst amateurs, for schoolboys take copper "shells" off their plaster medallions, and modellers in wax and clay make permanent records of their artistic skill in the easily-worked copper process. Silver-plating and gilding, too, are practised by large numbers, and, though far more difficult to work with success, form interesting and sometimes profitable diversions. Though M. Fontaine, as a matter of course, describes the principal details of battery processes, the more valuable portions of his work deal with the application of the dynamo machine as the generator of current for the factory, and he divides the book into four principal sections, the first of which deals with theory, the second with the various batteries and dynamos used in electrolysis, the third with the deposition of the metal, and the fourth with the newer processes for refining metals and treating ores. With the first section we have little to do here, because although the theory differs in the phraseology and terms used by different writers, it comes to much the same thing, so far as the practical worker is concerned. M. Fontaine seems, however, to have consulted a large number of authorities, and has given in one chapter a variety of tabular data which will be valuable to those who have no other works of reference. It appears singular, though, to find in the English edition that "M. Sprague's" law on electrolysis—"the substances which, in becoming freed, absorb the smallest quantity of intrinsic energy are those which are liberated at the electrodes"—is the converse of that which M. Berthelot designated by the name of "principle of the maximum work." "M. Sprague's" law is, however, acknowledged as a "new conception"; but surely the printers and the publishers knew, if Mr. Berly did not, that "M. Sprague" should be Mr. Sprague. M. Berthelot is said to have "enumerated" instead of ennunciated a principle, which, like the first, may be a printer's error, but on p. 147 we find a more serious slip, which a translator from French to English should have especially guarded against. Thus we are told that "the deposition [silver] is begun with a current the electromotive force of which does not exceed 2 or 3 volts, and the intensity 50 ampères per square mètre." The unit names being given the student is not likely to be misled, but it would be better to avoid the term "intensity" applied in that connection. In the chapter on batteries we read "for thin depositions, and especially when the work is intermittent, Leclanché and Lalande and Chaperon's cells can be used, as also generally all cells having the property of giving a regular current for a long time, without wasting when not at work." Whatever may be the merits of the Lalande-Chaperon (oxide of copper) cell, the Leclanché can scarcely be adopted with advantage for electro-metallurgy, even when constructed, as M. Fontaine gives it, with agglomerate plates composed of 40 parts binoxide of manganese, 52 of carbon, 3 of bisulphate of potash, "5 of gum lac rosin acting as a cement to unite the two other substances." This mixture, he says, is heated to 100 degrees centigrade (212 Fahr.), and then submitted to a pressure of 4,500lb. to the square inch. The introduction of the word "rosin" tends to confuse, and the passage should probably read "gum lac resin," though "lac" simply, or "shellac," would be clear enough. M. Fontaine says that the Leclanché cell can be used with advantage in electrolytic operations when the baths have a great resistance, and he goes on to enumerate its advantages, but we should not advise its employment for any electrolytic purpose. Of the Smee cell, he says it is extensively used in England and America in small nickeling and electrotyping works, and is particularly applicable for operations in which the current must be energetic at the beginning and weaker afterwards. In France it has been almost forgotten, notwithstanding its economy. Of thermo-electric generators, he mentions and illustrates the Noé and the Clamond, the former being frequently used in Austria by goldsmiths, but M. Fontaine settles the latter by the statement that one cubic mètre of gas would develop through a Clamond a maximum power of 5 kilogrammètres, whereas the same quantity of gas consumed in an Otto gas-engine develops over 75 kilogrammètres. That statement shows very conclusively that thermo-electric batteries cannot compete with a gas-engine and dynamo, but amateurs and other dabblers in electro-metallurgy will probably find the Daniell or the Smee, all things considered, the best arrangement they can adopt, unless they do not mind the trouble involved in the use of the Bunsen, the objections to which are the poisonous fumes and the labour of cleaning up and recharging, although it is said that M. Dupré has succeeded in suppressing the nitrous vapours by using a depolarising liquid in which 77gr. of potassium dichromate have been dissolved per litre. In contact with the zinc he uses acidulated water or potassium disulphate. The dynamos described and illustrated are the Siemens, Gramme, Schuckert, Mather, Weston, and Elmore; but Wilde's machine comes in for some commendation as a device "the most perfect and the most generally used in industry before M. Gramme's conception made its triumphal appearance." Gramme unquestionably made a great step in advance, so far as electro-metallurgy is concerned, and the willing testimony of Messrs. Christofle is accorded to the fact that with the best batteries they had employed the cost of depositing was 3·87 franc per kilogramme for current alone, whereas with the Gramme machine it was reduced to 94 centimes, or less than one-fourth. These figures are the result of careful calculations based on five years' work at the factory of Messrs. Christofle, and are given on the authority of M. H. Bouilhet, chemist to the firm. It is evident, then, if evidence of the fact were needed, that the small man who employs a battery, and obtains his current from the combustion of zinc, cannot compete with the factories where a dynamo can be put down; but it is not unlikely that Mr. Kendall's gas battery, which we illustrate (in principle) elsewhere, will enable the amateur to compete on favourable terms with the large factories, as it is small and compact, and is readily worked by a gas blowpipe. In his table of the electromotive force of different cells, M. Fontaine gives the oxide of copper cell at ·8 to ·9 volt; but it is doubtful if it will maintain that for long. The third section opens with a chapter on "Nickel-Plating," in which it is stated that the purity of the salt of nickel is the primordial condition for the preparation of a bath giving good deposits. The selection of the water, too, is most important—waters from "rivers, sources, wells" (*sic*) being often defective from the salts contained in solution: hence, M. Fontaine says the best plan is to use distilled water, or in the case of large baths rain-water. For iron articles he advises the use of M. Pérille's system, which is 80 grammes of double sulphate of nickel and ammonium for each litre of water, mixing with the latter in an enamelled vessel when the temperature is at boiling. The solution should be filtered into the vat, letting it cool previously if the latter has a lining of guttapercha. The bath should be of. 6 – 8 degrees Baumé, and scarcely redden litmus paper. Before the iron is placed in the nickeling solution it is scoured and cleaned in an acid bath, which latter may be composed of water five, hydrochloric acid one. M. Fontaine rightly insists on the great importance of the preliminary operations, and gives the various processes adopted by Pérille, Pfanhauser, Elmore, and others. As to the E.M.F. required, he says experience shows that a good dynamo for nickel-plating must have an electromotive force capable of varying between 1 and 8 volts, and proceeds: "Mr. Sprague, who should always be consulted on matters of electric intensity or electromotive force, recommends beginning with five volts and finishing with about one." Silvering and gilding are treated at considerable length, and there is a useful chapter on electrotyping, and another on the deposition of various metals, including brassing and bronzing. Section IV. contains two chapters dealing respectively with the refining of copper and lead, and the treatment of ores by the electric method—a method which is being much more extensively utilised now that powerful and comparatively cheap dynamos are available. The object is to produce chemically pure copper, and not unfrequently considerable quantities of gold are obtained from the baths — for instance, the Norddeutsche Affinerie at Hamburg secured as much as 1,200 kilogrammes of fine gold in 1880; but then they produce about 2½ tons of chemically pure copper per day, and, consequently, deal with immense quantities of the crude material. The Elliott Metal Company, Selly Oak, near Birmingham, refine 10 tons of copper per week, and employ five improved Wilde dynamos, in which the armature carries a series of bobbins, which revolve between the free extremities of a number of cylindrical electro-magnets, arranged in a circle on each side of the armature, the bobbins of which have iron cores, thus differing from the Siemens alternating current machines. In this chapter M. Fontaine refers frequently to the experiments of Mr. Sprague, and also gives much information of a practical nature, and many useful data obtained from the practice at different factories. The Electro Metal Refining Company, of New York, work Keith's process; and referring to a statement that Mr. Weston had promised to supply a dynamo for £40 which will precipitate 40 tons of lead in twenty-four hours, M. Fontaine says that the power required will be 48 h.p., and that a dynamo capable of doing such work as that will cost the manufacturer at least £300. As to the treatment of ores, M. Fontaine refers to many of the best-known processes, patented and otherwise, but expresses the belief that there is not a single industrial application of electricity for the purpose. Hence he confines his remarks to descriptions of those processes which appear most ingenious and easy of realisation, and so concludes a work which is decidedly a useful addition to the literature of electro-metallurgy, and will be welcomed by those practically engaged in the industry.

---

* Electrolysis. By HIPPOLYTE FONTAINE, translated by J. A. BERLY, C.E., A.S.T.E. London and New York: E. and F. N. Spon.

## ASTRONOMICAL NOTES FOR SEPTEMBER, 1885.

### The Sun.

| Day of Month. | Souths. | At Greenwich Mean Noon. Right Ascension. | Declination. | Sidereal Time. |

| 26 | 11 57 11·53 ,, | 12 13 0 | 1 24 34 S | 12 21 48·90 |

The method of finding the Sidereal Time at Local Mean Noon at any other Station will be found on p. 355 of Vol. XL.

Spots and other signs of solar activity are visible at intervals on the Sun's disc.

At 9 p.m. on September 22nd the Sun is said technically to enter Libra, and Autumn is supposed to commence. This, however, refers to the "Sign," and not to the Constellation, as at the instant specified the Sun is just below a line joining β and η Virginis, but nearer to the latter star.

The Zodiacal light may now be seen in the East before sunrise.

There will be an eclipse of the Sun on September 8, which will be total in New Zealand. As it will be wholly invisible here, this mention of it must suffice.

### The Moon

Enters her Last Quarter at 5h. 14·8m. a.m. on September 2nd, and is New on the 8th at 8h. 43·2m. at night. She will enter her First Quarter at 6h. 14·8m. in the early morning of the 16th, and be Full at 7h. 54·7m. a.m. on the 24th.

| Day of Month. | Moon's Age at Noon. | Souths. |
|---|---|---|
| | Days. | h. m. |
| 1 | 22·0 | 4 56·6 a.m. |
| 6 | 27·0 | 9 44·4 ,, |
| 11 | 2·6 | 2 11·3 p.m. |
| 16 | 7·6 | 6 14·6 ,, |
| 21 | 12·6 | 10 6·4 ,, |
| 26 | 17·6 | 1 11·7 a.m. |

The Moon will be in conjunction with Saturn at 3 a.m. on the 4th; with Mars at 7 a.m. on the 5th; with Mercury at 4 a.m. on the 8th; with Jupiter at 10 o'clock the same night; and with Venus at 10 a.m. on the 11th.

### A Partial Eclipse of the Moon

Will be partly visible at Greenwich on the morning of September 24th. It may suffice to say here, in connection with it, that the first contact with the Penumbra will occur at 5h. 2.1m. a.m.; but as the Moon sets at 5h. 45m. before contact with the shadow proper has happened at all, all that will be perceptible in this country will be a slight shading of her Eastern limb.

### Occultations of (and near approaches to) Fixed Stars by the Moon.

† Near approaches. ‡ Stars below the horizon.

The observer possessing an equatorially-mounted telescope should look out for the Occultation of Aldebaran on the morning of September 29th, of which the details are given above. It is not predicted in the *Nautical Almanac*.

### Mercury

Comes into Inferior Conjunction with the Sun at 6 p.m. on the 2nd, and is a Morning Star during the entire month, attaining his greatest elongation West (17° 51′) at 7 p.m. on the 18th. About this time he may be well seen before sunrise. His diameter decreases from 10·4″ on September 1st to 5·4″ by the 30th.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 10 46.0 | 3 26·1 | 0 2·8 p.m. |
| 6 | 10 31·1 | 6 13·5 | 11 28·2 a.m. |
| 11 | 10 24·9 | 8 32·3 | 11 2·4 ,, |
| 16 | 10 32·3 | 9 24·5 | 10 50·1 ,, |
| 21 | 10 52·3 | 8 32·2 | 10 50·4 ,, |
| 26 | 11 20·4 | 6 11·7 | 10 58·8 ,, |

The somewhat complicated path thus described by Mercury lies in Leo (to a small extent in the N.E. corner of Sextans), and finishes in Virgo. On the morning of the 13th, Mercury will be some 48′ South of ρ Leonis, but will not approach so near to any other star of any size throughout his course.

### Venus

Is an Evening Star throughout September, and may possibly be caught just above the horizon after sunset; but as a telescopic object she is very destitute of interest, as her diameter, which is 12·4″ when the month begins, only increases to 14·2″ by the 30th. She is perceptibly gibbous now.

| Day of Month. | Right Ascension. | Declination South. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 12 41·1 | 3 49·0 | 1 57·5 p.m. |
| 6 | 13 3 0 | 6 22·5 | 1 59·7 ,, |
| 11 | 13 25·1 | 8 53·0 | 2 2·1 ,, |
| 16 | 13 47·5 | 11 18·9 | 2 4·8 ,, |
| 21 | 14 10·1 | 13 38·9 | 2 7·7 ,, |
| 26 | 14 33·1 | 15 51·3 | 2 10·9 ,, |

Whence it will be seen that Venus traverses a good deal of Virgo, and enters Libra towards the end of the month.

### Mars and Jupiter

(Who comes into Conjunction with the Sun at 10 p.m. on the 8th), are both invisible; but

### Saturn

Is coming into view again as a Morning Star. He rises, though, on the 1st at 11h. 32m., and by the end of the month at about a quarter to 10 o'clock at night. His equatorial diameter subtends an angle of 15·8″ on September 1st, increasing to 16·6″ by the 30th. His ring system is almost as open as it can be, and every week is now bringing this splendid object into a more favourable position for observation.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 6 27·1 | 22 21·5 | 7 44·6 a.m. |
| 6 | 6 28·8 | 23 23·8 | 7 26·6 ,, |
| 11 | 6 30·4 | 22 22·2 | 7 8·5 ,, |
| 16 | 6 31·7 | 22 21·2 | 6 50·2 ,, |
| 21 | 6 33·0 | 22 20·2 | 6 31·8 ,, |
| 26 | 6 34·0 | 22 19·3 | 6 13·1 ,, |

In pursuing this short path, Saturn forms a triangle of varying shape with μ and ν Geminorum.

### Uranus and Neptune

Are still both invisible.

### Shooting Stars

Are rare in September. The night of the 10th is that on which they will most probably be seen.

### Greenwich Mean Time of Southing of Twelve of the Principal Fixed Stars on the Night of September 1st, 1885.

| Star. | Souths. h. m. s. |

The method of finding the Greenwich Mean

Time of Southing of either of the Stars in the above list for any other night in September, as also that of determining the local instant of its Transit at any other Station, will be found on p. 356 of Vol. XL.

---

## THE INTERNATIONAL INVENTIONS EXHIBITION.—XVII.

### Musical Instruments, &c.

THE division of the Exhibition devoted to musical instruments is chiefly remarkable for the splendid display of pianofortes, which are shown in all sorts of cases and in all sorts of styles, the larger makers apparently endeavouring to outstrip one another in the magnificence of their exhibits. Unfortunately for the public, and perhaps for the makers themselves, there is not much to be learned from the inspection of pianofortes as they are here exhibited, for in the majority of cases it is only the handsome exterior that can be seen, though a few exhibitors have done something to make their stalls instructive as well as attractive. The would-be purchasers of pianofortes, who go to the Exhibition with the idea of selecting an instrument, will find themselves sorely puzzled to make a choice, and many of them will probably withhold the order until they have taken expert advice. With a few exceptions, it may be said that all the great pianoforte-makers send specimens of their productions, but taking the division as a whole it is rather disappointing, for it is only a small percentage of the exhibitors who show the public anything more than the outside of their instruments; and not a few of the exhibits of musical instrument-makers are little more than "shop-front" advertisements. There is this advantage, however, so far as the visitors are concerned, that they can see in a comparatively small area a variety of instruments which they could not otherwise inspect, except at the cost of travelling from point to point—which means a good deal of hard work in London—and if they cannot handle the exhibits they can at least see what has been done. The preface to this division is from the pen of Mr. W. Barclay Squire; but it deals very briefly with the improvements in musical instruments, and contains some curious statements. Hawkins is rightly credited with the honour of being the inventor of the iron piano frame; but the following sentences scarcely give a correct idea of the history of the popular free reed instruments:—"The harmonium was completed as an invention by Debain, a Frenchman, in 1840; but the expression, which permits varying intensities of sound, was subsequently added by Alexandre. The now popular American organ, in which the wind is sucked instead of blown, was introduced by Mason and Hamlin, of Boston, U.S., about the year 1860." The harmonium is a natural development of the seraphine, and the now popular American organ is a development of the melodeon, and both had their origin in the patent granted by the United States to Aaron Merrill Peasley in 1818, though instruments of some kind having free reeds appear to have been known in Paris so early as 1810. It is generally conceded that M. Martin was the inventor of the harmonium, and it is indisputable that the late Emmons Hamlin made Carhart's melodeon into the American organ by his discovery of the art of voicing free reeds. To turn, however, to the exhibits, we must leave the large pipe organs for notice later on, and, for obvious reasons, cannot do more than notice the chief objects of interest in the other branches of the division. There are many pianos, harmoniums, reed organs, and other instruments collected here which have no special feature to recommend them, and which, as a matter of fact, are very ordinary productions. The chief novelty amongst the pianos is the organo-piano of Metzler and Co., Great Marlborough-street, W., in which a series of light hammers are kept in rapid motion by working a treadle placed near the right pedal. When a key is depressed the light hammer corresponding is brought into contact with the strings or "chord," and a sustained sound is produced. The hammer proper fulfils its own purpose; but, as it does not deliver its blow unless the key is "struck," it is possible to produce tones which resemble nothing so much as a stop on an American organ, while, at the same time, the pianoforte tone is available instantly. In the hands of a skilful player the effects produced are pleasing, and the device is, we presume, the best that has been done towards developing the sostenente piano. At the same stand is a Mustel harmonium, an instrument that many visitors will be glad to see. Brinsmead and Sons, Wigmore-street, W., besides several of their ordinary patterns, show a drawing-room grand, with the patent tone-sustaining mechanism and pedal, and a skeleton piano—that is, a complete action which, to preserve it from dust, is kept in a case with glass doors. Various portions are also exhibited at this stand, including the patent screw-tuning apparatus. Several makers seem to have abandoned the peg driven into the wrest-plank, and the Mason and Hamlin Co. exhibit a piano with a new system of stringing, in which the tuning pegs are square-headed screwed pins, which take a bearing on a ridge of the iron frame, the strain being thus direct with the length of the pin, instead of at one side and transverse. M. Alibert, of Paris, exhibits improved pegs for pianos and violins, which are intended to avoid all risk of slipping. Messrs. Broadwood and Sons, Great Pulteney-street, W., besides specimens of modern instruments, exhibit the original cottage pianoforte invented by Hawkins in 1800, Wölfel's iron back, with compensation rods, cast in 1867, and some instruments which have a special history attaching to them, such as that played upon by Chopin in 1848. The Rev. G. T. Driffield, rector of Stratford-le-Bow, exhibits, under the care of Messrs. Broadwood, Handel's tuning-fork and an old tenor fork; while at the stand can also be seen a number of Mr. Ellis's forks which have been measured by Appunn's tonometer. In the Albert Hall, in the loan collection of musical instruments, manuscripts, books, paintings, and engravings, Messrs. Broadwood exhibit a piano made by Johannes Zumpe in 1766. It is believed to be the oldest "square" in existence, and has 18 keys to the octave. They also show the grand piano and seat which they made for Mr. Alma Tadema, enriched with paintings by that distinguished artist, and inlaid with ivory, tortoiseshell, and mother-o'-pearl. It was illustrated in the *Building News* of Sept. 1, 1882. Most of the other large pianoforte makers have exhibits; but as a rule it is only the casework that attracts the attention of the public. Steinway and Sons, of New York, however, show their frames, and illustrate the numerous patents they have obtained. The steel frame and the laminated woodwork of these famous pianos attract much attention. Mr. Stiles, of Southampton-row, W.C., exhibits specimens of the pianos of Bord, of Paris, which have deservedly obtained a high reputation; and Carl Hofmann, of Vienna, shows what is probably the "smallest grand" in the world, as it is only 4ft. 10in. long. Mr. Rudd, of Dean-street, W., sends a grand piano by Muzio Clementi, which has been restored. Clementi is called the father of piano music, and this instrument is of peculiar construction, having an extra harmonic pedal, and a double length of vibrating string to each note, in order to obtain continuity of sound by the sympathetic vibration of a string carried over an additional bridge called the "bridge of reverberation." Actions are shown by a number of makers, and all claim improvements; but it is curious to note with what simplicity some of the foreign exhibitors send modifications of the famous Erard action, presumably expecting them to be considered as "inventions." The Comte de Nydpruch, of Brussels, exhibits a piano with the action made of metal-band, worked up into the required shape. The stickers, hammer-shanks, &c., are all made of metal, and it is possibe that in certain conditions the advantages may be considerable. Amongst other novelties connected with pianoforte-making we may note the tuning machine of Messrs. Schucht and Schönewald, of Store-street, W.C., in which the "hammer" is connected to the "key" by toothed pinions, and one turn of the former gives half a revolution on the tuning peg. Their hammer covering machine is an ingenious device, as by its aid the hammers can be refelted in situ. Mr. Outram, of Greetland, Halifax, exhibits his patent system of stringing, in which the strings are taken on both sides of the frame, passing over pulleys at the bottom and top, one pulley being carried in a shoe, which can be drawn up by means of a headed screw, so as to put the required tension on the string for tuning. Mr. Nosworthy, of Coldharbour-lane, S.E., exhibits a dissecting model, showing his method of relieving the soundboard of a portion of the down-pressure by dividing the string scale between two soundboards. Mr. A. Squire, of Wrotham-road, N.W., shows models of his pianoforte action, which is appreciated by many good makers; and amongst the folding or cabin pianos, those of Venables and Co., of Essex-road, N., are worth notice, especially as the hammers are waterproofed, and the parts are prepared to resist the injurious effects of damp atmospheres. Mr. T. Machell, of Glasgow, exhibits what is known as a tuning-fork piano; but although his arrangements are ingenious, we are afraid they are not improvements on the older-fashioned plan of wires. Messrs. Whitfield and Co., of Birmingham, have a good exhibit of cast-iron frames for pianos, which are tolerably well known to the trade, and altogether the show of "fittings" will be useful to the makers and to amateurs. Two or three exhibitors show the application of pedals to pianofortes; but the recently patented devices of Mr. Rushton, Child's Hill, N.W., are probably the best, as his simplex and independent attachments are applicable to pianos with under or over dampers. The piano can be lifted off the pedal portion and replaced again, as often as desired, without removing a screw or altering any of the arrangements. There is no attachment to the keys, the whole of the work belonging to the pedal action, except that connected to the pedal frame, being in the case of the piano itself. Amongst free reed instruments of the keyboard type we may note a voice harmonium by Mr. Colin Brown, of Anderson's College, Glasgow, with eight digitals in each octave, and the fingering the same in all keys of the scale. We described and illustrated this invention in Vol. XXIII., pp. 298, 320, 630. Mr. Brown also exhibits one of his monopolytones. Forsyth, Bros., of Regent-circus, W., have a selection of Dominion organs (American), and show in model and diagram the method they adopt of connecting the sub-bass to the manual and the pedals. Most of the best known makers of American organs and harmoniums have samples of their productions; but the only novelty seems to be the combination instrument of Jones and Co., Bristol, which has the exhaust system applied to the upper manual, and the pressure, or harmonium system, on the lower manual. Another instrument has this arrangement reversed. Mr. G. Cousins, of Birchington-on-Sea, exhibits a harmonium showing what is termed a method of tuning reeds so that they can be quickly raised or lowered in pitch to suit any other instrument. So far as can be seen, it consists of a clip to grasp the heel of the reed, which is worked by a thumb-screw from the rim of the "pan." The reed organs and harmoniums are mostly in a sort of annexe to the Central Gallery, and in the east end of this annexe will be found an ingenious hydraulic engine by Mr. Blennerhasset, of Vernon-street, W.C., blowing a double manual pedal harmonium by G. L. Bauer. The inlet valve of this engine is a simple three-way cock, the position of which is altered by a tappet arrangement. The supply valve is a cylindrical plug, which fills more or less of the pipe, and shuts off the water without any shock. The most ingenious part of the engine, however, is the arrangement for controlling the speed by the exhaust; a rod attached to the rising bellows of an organ connecting to a lever which closes the exhaust valve as the bellows becomes full, thus slowing the engine by back pressure. Mr. Blennerhasset shows his motor at work on a bellows supplying an organ a little distance away, and also employs it for driving a printing machine. The great four-manual concert organ by Messrs. Michell and Thynne, erected in the music room, is blown by two of these hydraulic engines, which are also applied to the model great organ by Brindley and Foster, and a three-manual pedal Mason and Hamlin American organ, exhibited by Messrs. Metzler. The vocalion of Mr. Baillie Hamilton, embodying that inventor's latest designs in connection with harmoniums and free reeds, can be seen in the department marked Siam on the plan, and on Friday afternoons there is usually a performance, in which its capabilities, which are great, are well shown. Fittings for free reed instruments are shown by a few makers, and concertinas are exhibited by two of the best known makers. There is a good display of other instruments, brass and "wood," the latter being a technical term which, we suppose, would include the cut-glass concert flute exhibited by Mr. W. H. Beeby, of Ridinghouse-street, W. Violins are exhibited by several of the best makers, and Mr. Twining, of Twickenham, exhibits a cellino or lady's violoncello, which is strung an octave below the violin. Messrs. Taylor, of Lower Edmonton, exhibit their patent double-strung violins, which simply duplicate the strings of the ordinary pattern, with what advantage remains to be proved. Mr. A. Cary, of Newbury, has a stand near Willis's great organ, at which he exhibits violins and their accessories, including the Spohr adjustable chin-holder, which we described on p. 318, No. 1,029; the patent bow guide of S. Williams, which prevents the bow swerving from its proper course, and sundry folding and portable music stands. Violinists will look admiringly at the fine case of bows by Mr. Tubbs, of Wardour-street, and not a few visitors will smile at the "amateur made" banjoes of Mr. Tallack, Selhurst-road, Norwood —not at the instruments, but at the phrase, for there are amateurs and amateurs, and the exhibitor in this case, we presume, merely wishes the public to understand that he is not a professional maker. G. Tiefenbrunner, of Munich, exhibits some beautifully-finished zithers; Thibouville-Lamy and Co., of Charterhouse-street, E.C., show, amongst their other exhibits, the pianista, which was described in recent volumes; and there are a variety of the now familiar automatic instruments of the organette type, in which the sounds are obtained by drawing sheets of perforated paper over the orifices of the tubes or cavities containing the reeds. The loan collection in the lower rooms and the gallery of the Albert Hall will interest many, for probably no exhibit of the like kind has ever been made before, and it will not be easy again to get together such a collection of ancient and historical instruments, and of manuscripts, prints, and paintings relating to music. A guide and catalogue has been recently published by Messrs. Clowes, to which Mr. A. J. Hipkins has written a preface.

## THE FIELDING HIGH-SPEED ENGINE.

We mentioned on p. 338 that Messrs. Fielding and Platt, of Gloucester, have at their stand (1193, West Annexe) in the Inventions Exhibition a very remarkable rotary engine, which almost baffles description. This "engine" may also be used as a liquid meter or a pump, and the following may be found probably as clear an account of its action as can be written. The motor is shown driving a dynamo; and a full-size model is available for inspection at the stand. The invention has been patented by Mr. John Fielding:—When two revolving shafts whose axes are inclined to one another at a considerable angle, such as 150°, are connected together by a universal joint, consisting of a gimbal ring, jointed at two opposite points to two arms projecting from the one shaft, and at two points 90° from the former to two arms projecting from the other shaft, each of those points of the gimbal ring, besides revolving around the point of intersection of the two axes, has a librating movement relatively to an imaginary central plane bisecting the angle at the intersection of the axes, and therefore moves from the one side of such a plane, across it, and to the other side during the one half of each revolution, and back during the other half revolution. If then a boss, in the form of a piston, projected from the ring at one of the joints in the direction opposite to the arm, which there connects the ring to the one shaft, and if this piston entered a cylindrical cavity carried on the other shaft, the librating movement above referred to would cause a to and fro reciprocation of the piston in the cylinder. As this movement is not in a straight line, but in the arc of a circle struck from the point where the axes of the shafts intersect, the cylinder has to be made as if its axis were bent to this curvature, so that it is really a portion of a bent tube, the piston having a corresponding form. Now, if by means of a suitable slide or valve fluid under pressure were admitted to the cylinder during the one half of each revolution of the shafts and were emitted during the other half revolution, the pressure of this fluid would cause the shafts to revolve; and, conversely, if the shafts were caused to revolve by extraneous power, fluid would be drawn into the cylinder during half of each revolution, and would be expelled during the other half revolution. The invention relates to the construction of apparatus, which, acting in the manner set forth above, may be employed as a motor when it is supplied with fluid under pressure, or as a meter of liquid passed through it, or as a pump when it is driven by extraneous power. In order to make the apparatus effective during both halves of each revolution, two cylinders and pistons, as referred to, are arranged diametrically opposite to one another on each side of the ring, so that while the one cylinder is discharging the other is receiving fluid; and, in order to provide against the dead centre at each change of direction of movement, the patentee preferably duplicates the arrangement by providing another pair of cylinders and pistons at the extremities of a diameter at right angles to that which joins the former pair, and on the other side of the ring. For governing the admission and emission of fluid, passages are made in revolving bosses, carried on the shafts, presenting facings against which bear stationary slides, so that as ports in these facings pass, in their revolution, corresponding ports in the slides, the fluid flows to and from each of the several cylinders alternately in the succession of their rotation. The accompanying drawings represent the construction and arrangement of a rotary motor of the kind described, which may be worked by steam or other fluid under pressure. Fig. 1 is a longitudinal section, and Fig. 2 is a plan; Figs. 3 and 4 are respectively side and front views of the gimbal ring; Fig. 5 is a front view of the stationary slide and the passages to and from it. A and B are the two shafts mounted in long bearings at an angle to one another, and having bosses *a b* fixed on them. The shaft B serves as a pivot, and does not communicate motion to other machinery. C is the gimbal ring, which is jointed by pins *e* to two arms projecting from the boss *a* and to two arms projecting from the boss *b*. The centres of the joints *c* are in one plane, but the ring C, as shown in Fig. 3, has recesses on each side to allow play for the moving parts, and, for convenience of construction, is made in four pieces, bolted to-

FIG. 1.

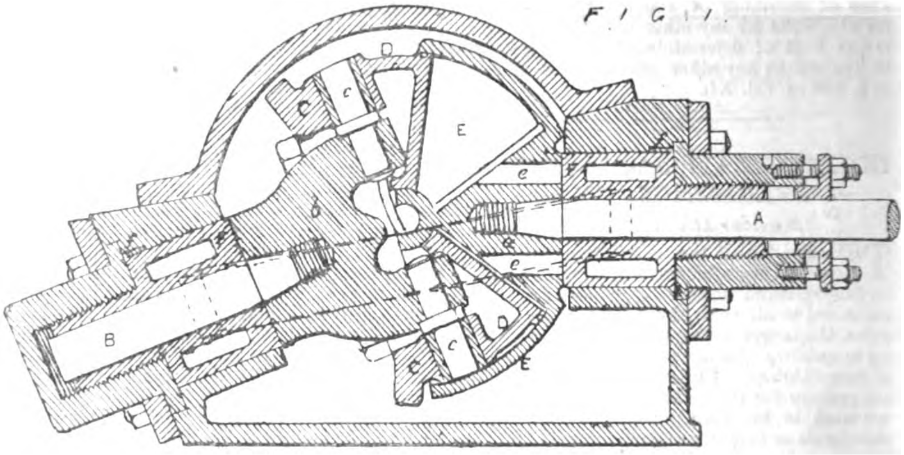

FIG. 2.

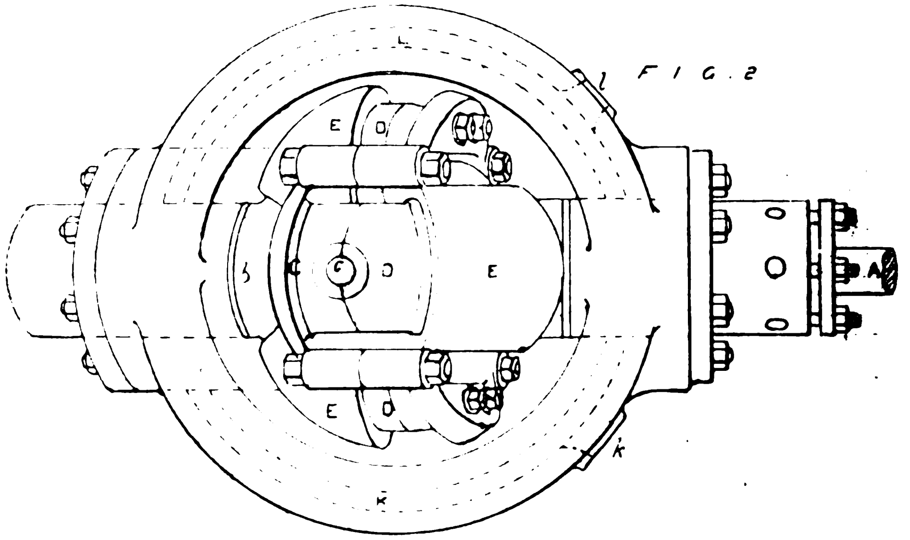

FIG. 3.

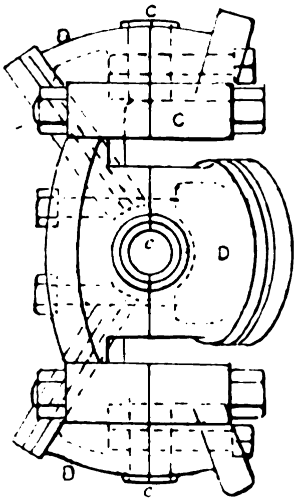

FIG. 4.

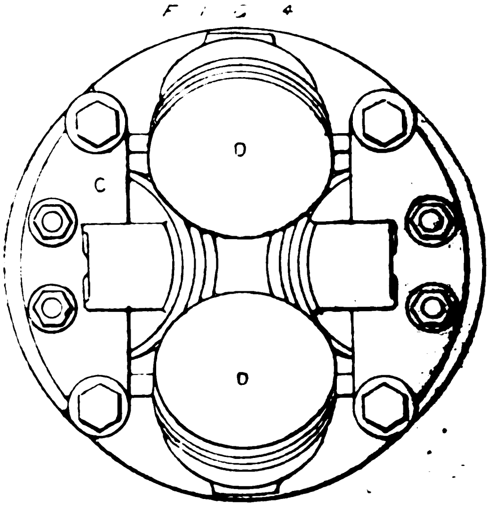

gether. From the ring C, on each side of it, project the two pistons D, each of which enters a cavity E, which, as explained above, has the form of a portion of a bent tube, but which, for the sake of brevity and perspicuity, is termed a cylinder, as it plays the part of the cylinder of an ordinary engine. These cylinders are formed, two of them in the body of the boss *a* and two in the body of *b*. Each cylinder has a passage, *e*, opening as a port in the facing against which bears the slide F, which is prevented from revolving by a key *f*. Within the body of the slide there is an annular chamber divided into two compartments, the one opening by a port G and the other by the longer port H to the facing. The slides F form bearings in which the shafts A and B revolve, and these slides are held within bosses of the fixed framing which are connected together by two semi-annular passages, K and L, the passage K opening into the G compartment of each slide, and the passage L into the H compartment. The passage K receives at *k* a supply of steam or other working fluid, and the passage L has an outlet, *l*, for discharge. As the two shafts revolve along with their cylinders E and with the gimbal ring C and its pistons D, the port *e* of each cylinder as it passes the port G of the stationary slide admits fluid to the cylinder, and as it passes the port H of the slide it allows fluid to issue from the cylinder. The slide F being in each case fixed in such a position that its ports G and H communicate with *e* during those parts of a revolution which correspond respectively with the outward and inward movements of the pistons D relatively to their cylinders E, the supply of steam or fluid under pressure causes the shafts to revolve, or, if the shafts be caused to revolve by extraneous power, fluid is drawn in at *k* and expelled at *l*. When steam or other elastic fluid is employed to work the motor, the inlet ports G are made, as shown in Figs. 5 and 6, considerably shorter than the outlet ports H, so that a comparatively small charge of elastic fluid may be admitted to each cylinder, in which it can act by expansion. When water or other liquid under pressure is employed, or when the apparatus is used as a meter or pump for liquid, the inlet ports G are necessarily extended so as to be open to *e* during the whole outstroke in each case.

FIG. 5.

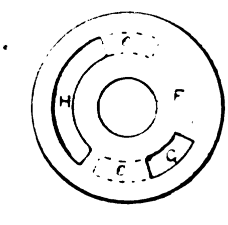

FIG. 6.

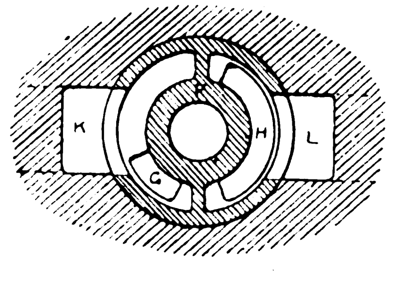
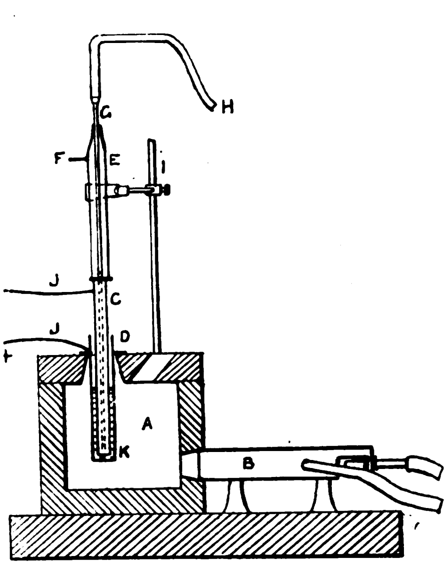


## KENDALL'S GAS BATTERY.

THE gas battery or electric generator exhibited by Mr. J. A. Kendall, of Middlesbrough, at stand 1,334, Inventions Exhibition, is specially worthy of notice, because it is an attempt to obtain electricity direct, without incurring the losses which must attend the use of the steam boiler, engine, and dynamo. Several inventors have endeavoured to obtain electricity from the oxidation of coal, carbon, or hydrocarbons without the intervention of the steam-engine, which wastes nine-tenths of the potential energy of the fuel, and Mr. Kendall's device, as probably the forerunner of other notable inventions, deserved even more than the silver medal it obtained. The battery is based upon the well-known phenomenon of hydrogen passing through platinum at a red heat, two platinum plates being used as the poles, one exposed to hydrogen and the other to oxygen. These plates are arranged in the form of concentric tubes closed at one end, and are separated by a fluid medium of fused glass. Hydrogen gas is continuously supplied to the inner platinum tube, while the entire apparatus is maintained at a high temperature by means of a furnace fed with coke or liquid or gaseous fuel. In the exhibit a Fletcher's gas blowpipe is used. The absorption of hydrogen by the platinum is accompanied by electric generation, and the current is led away by wires connected to the platinum tubes It is curious, however, that so long as the two platinum tubes are not connected by a metallic circuit, the passage of the hydrogen is slow; but that as soon as the electric circuit is completed the rate of flow is suddenly increased, and is steadily maintained at the higher amount. The speed at which the hydrogen will pass in a single cell may be gathered from the following experiment:—A platinum tube, K, 2¾in. long and ⅜in. in diameter, closed at one end, was soldered to a strong iron tube, E, and fixed vertically. The platinum tube was immersed for 2¼in. in fused glass contained in a platinum cell, D. This latter was 2¾in. deep and 1in. in diameter. The two platinum tubes were connected by platinum wires, J, with the galvanometer, and the iron tube was connected with a Sprengel pump by the tube H. The cell being heated to bright redness in an oxidising flame, a good vacuum was produced by the Sprengel pump. Then, while no bubbles of gas came down the fall tube of the pump, the galvanometer showed no deflection. The cell was then heated by a reducing flame. The galvanometer soon gave a steady deflection of 15deg., and bubbles of hydrogen came down the fall tube of the pump. The experiment was continued for half an hour, and during fifteen minutes the hydrogen coming down the fall tube was collected. It measured 1·33 cubic centimètres. The figure illustrates a single cell of the battery, and serves to explain the principle; but, at the Exhibition, a cluster or group of cells is shown, in order that the compactness of a gas battery on this principle may be understood, for one gas-blowpipe heats the group. According to Mr. Kendall, the E.M.F. of a cell is about ·7 volt, which is less than the theoretical efficiency; but the remaining energy appears to be developed in the shape of heat at the oxygen plate, and thus serves a useful purpose by keeping up the temperature of the apparatus. It is not necessary to use hydrogen, for in passing through the inner tube K, the gases are separated, the hydrogen being filtered off while the residuals are drawn off at the escape F, and can be taken to the furnace or blowpipe. Thus producer gas, a compound of hydrogen and carbonic oxide, will serve admirably for working this battery, which certainly promises to occupy a wide field of usefulness.



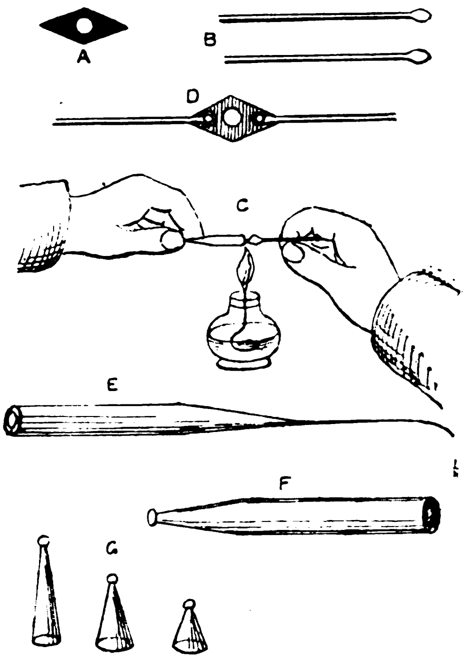
## ELECTRICAL INSTRUMENT-MAKING FOR AMATEURS.—II.*

By S. R. Bottone.

§ 5. SOLDERING WITH A FLAME.—In many instances a better joint and neater looking work can be made over the flame of a spirit or other lamp than with the soldering-iron. This is more especially the case in small work, such as joining wires, soldering pivots, &c. As an example, let us suppose we desire to make a poised magnetic needle out of two similar pieces of needle, joining them together by means of a short tinned-iron junction, in which the pivot is inserted. (It is evident that a pivot could not well be attached to an ordinary sewing needle were the needle in one piece.)

The needles (of which two are required) are broken off of the desired length by means of a pair of nippers. The heads may be the portions rejected, if a very light needle is required: the points, if a heavier needle be not objectionable. Care should be taken that the pieces be of the same weight, to insure a well-balanced needle. A small piece of sheet tinned iron ("tin-plate") about 1in. square should now be procured and flattened out. With a screw-drill, or small punch, a clean central hole is made a trifle smaller than the largest external diameter of the pivot. (See § 6 for pivots). The piece is now cut into the shape of a small lozenge, as shown at Fig. 2, A, and again flattened out by a light blow with a flat-faced hammer. The needles are now to be lightly sandpapered at the ends which are to be soldered to the lozenge, then these extremities immersed in the chloride of zinc soldering fluid. The soldering-iron is then to be heated, and a little globule of solder caused to adhere to the prepared extremity of each needle by its aid. The needles should now present the appearance shown in Fig. 2 B. The spirit lamp is now to be brought into requisition. The flame should not be too high for such work, so that the wick need not be raised much. Taking up the lozenge-shaped piece in the left hand, with a pair of tweezers (or longish piece of wire bent to a tweezer shape), and allowing one half to project, we apply with a feather a little soldering fluid to the projecting point. The needle with its adhering solder is now taken up in the right hand (a small piece of paper being wrapped round it, to prevent the fingers being burnt), and both the needle and the lozenge are held for a few seconds over the flame of the spirit lamp, in the position they are desired to remain (see Fig. 2 C). The solder will soon be seen to flow. As soon as this is the case the pieces must be pressed firmly together, and both hands removed from over the flame of the lamp, care being taken to keep the parts constantly pressed together until a sudden *dulling*

FIG. 2.



---

* All rights reserved.

shows that the solder is set. In like manner the other needle is soldered to the other point of the lozenge. The needle may then be magnetised, and after magnetisation balanced on its pivot, as will be described further on. Fig. 2 D shows the needle ready for pivoting.

§ 6. *Pivots.*—These are in constant requisition; consequently, it is well to be able to make them of all sizes. The amateur will need only two kinds—viz., in brass and in glass. *Brass* pivots are very easily made from stout, hard brass wire. The most useful size is about $\frac{3}{16}$in. in diameter. A short length of this is placed in the jaws of a vice, with its circular section uppermost. A bit, capable of cutting a 3-16th hole, is placed in the screw-drill, and after being oiled, the drill is worked over the brass rod, the bit resting quite centrally, until the shoulders of the bit just touch the outside of the wire. This produces a good deep and evenly conical hole. The wire can now be removed from the vice, and the outside of the pivot also made conical by filing, while still on the brass rod; when the desired shape has been secured, it can be cut off with a fret-saw or file.

*Glass* pivots are extremely useful in all electrical experiments. The best way to make these is to soften a glass tube over a spirit lamp, and gradually but steadily pull it asunder. By so doing, two conical pieces are the result. If the extreme hair-like points of these are held over the lamp, they fuse up into a round globule, thus closing up the hole. The pivots thus produced can easily be cut off (when the glass is cold) by making a mark round the tube with a sharp triangular file, at the point where it is desired to break it off. On applying a little pressure between the finger and thumbs of both hands, the pivot easily breaks away from the remainder of the tube. The pivots may be made very long and thin, by allowing the glass to soften well, before beginning to pull asunder, and such long thin pivots are very useful for astatic galvanometers, or other cases in which two objects have to be poised on one pivot. Short pivots can be made by pulling asunder as soon as the glass softens in the flame. Fig 2 C shows how the glass tube should be held in the hands to soften over the flame. Fig. 2 E gives the appearance of the tube after pulling asunder. Fig. 2 F indicates how the hair-like extremity should be melted into a bead over the lamp, so as to close the capillary aperture, and Fig. 2 G shows finished pivots.

## THE MAGNETIC TELEPHONE.

WE have recently had an opportunity of testing a new magnetic telephone, the invention of Mr. E. J. Gillett, of the Signal Engineering Company, which has the promise of coming into extensive use, especially as the Company purpose to erect the lines and supply instruments outright for a moderate sum. The instrument is a modification—an important one—of what is known as the ENGLISH MECHANIC telephone, which was first described in an article on experiments in telephony, p. 551, Vol. XXIII. It is put up in vulcanite cases like the Bell receiver, and has a magnet and the usual bobbin of wire round the pole, but there the resemblance to the Bell instrument ceases, for the diaphragm is a membrane prepared in a special manner to protect it from the effects of the atmosphere. To this membrane is attached a piece of hardened steel, and that being attracted by the magnet, puts the diaphragm into vibration, and so transmits or receives the sounds produced by the voice of the speaker, as conveyed by the variations produced in the current. The instruments are thoroughly efficient, and are turned out in first-class style. As the ENGLISH MECHANIC telephone has been specially disclaimed from Bell's patent, it was only necessary to construct a perfect instrument according to the description given in the volume above mentioned, and that appears to have been accomplished by Mr. Gillett, for certainly speech can be clearly transmitted and received by means of the magnetic telephone of the Signal Engineering Company, which can be seen and tested on presentation of card at the offices of the Company, 181, High Holborn, W.C. A small illustration in our advertisement columns will give an idea of the shape and appearance of the instrument.

THE new volume in the "Nature Series" will be "Flowers, Insects, and Leaves," by Sir John Lubbock.

## EVOLUTION IN THE VEGETABLE KINGDOM.—II.

(*Continued from p.* 538.)

THE most powerful antagonism to this effort of Brongniart to confirm Lamarckian principles from the phytologic side thirty-one years before the appearance of Darwin's "Origin of Species" was offered by the eminent English botanist, Dr. John Lindley, who found a fitting occasion to meet the great French palæontologist on his own ground while engaged with William Hutton in the preparation of their "Fossil Flora of Great Britain," 1831—37. Of this truly great work we are here concerned only with certain discussions which were directed against the then infant doctrine of biologic evolution in the vegetable kingdom, and which were not only marked with great acrimony, but were allowed to influence and to warp the classification adopted by the authors into forms which even to botanists now appear ridiculous. The introductory remarks in the first volume, as well as much of the general discussion throughout the work, are characterised by a most astonishing and apparently wilful ignorance of the true principles of palæo-phytology as they were set forth by Brongniart, Sternberg, and even Schlotheim, and which are now universally accepted.

One of Dr. Lindley's remarkable aberrations was the pertinacity with which he contended for the existence of cactaceous and euphorbiaceous plants in the coal measures. It is true that Parkinson had seen a fancied resemblance between certain stems and those of large cacti, and similar guesses had been made by Volkmann, Walch, and other authors of the eighteenth century, when it was supposed that the counterpart of every fossil plant must be found in the living flora, but all these imaginings had been long since laid aside only to be revived by the leading botanist of Europe.

The theory of a former tropical climate in England and on the Continent of Europe was assailed, the existence of tree-ferns in the Carboniferous was denied, the relation of the Calamitæ to the Equisetaceæ questioned, and many other tolerably well established generalisations were remanded to the domain of doubt and discussion.

The true secret of this sweeping scepticism is, however, not far to seek. It is found in the more general denial, which was finally made, of the conclusion to which the acceptance of these rejected theories would naturally lead and had actually led M. Brongniart and others. The authors say: "Of a still more questionable character is the theory of progressive development, as applied to the state of vegetation in successive ages. In the vegetable kingdom it cannot be conceded that any satisfactory evidence has yet been produced upon the subject; on the contrary, the few data that exist appear to to prove exactly the contrary." All the denials and assertions made in the work opposed to Brongniart's teachings are made to support this view. The existence of Cactaceæ, Euphorbiaceæ, and other dicotyledons in the Carboniferous would negative development; the admission of a former tropical climate was a strong argument for the nebular hypothesis as well as for geologic progress; tree-ferns would argue such a former tropical climate; if Calamites could be shown to be a Juncus, a higher type would be found in Palæozoic strata than Brongniart believed to occur. Still another good point was thought to be gained by proving what is now admitted—viz., that coniferous plants occur in the coal. All botanists then held, as many still hold, that the gymnosperms were a subclass of the dicotyledons, co-ordinate with the dicotyledonous angiosperms. But, curiously enough, Brongniart had forestalled this argument by making the gymnosperms of lower type, intermediate between the cryptogams and the angiospermous phanerogams. By a special insight, characteristic of true scientific genius, he had used their lower geological position as a proof of their lower organisation—i.e., had postulated evolution as an aid to organic research—a method which is now becoming quite common, although unsafe except in the hands of a master.

Dr. Lindley laid much stress upon the fact "that no trace of any glumaceous plant has been met with even in the latest Tertiary rocks," thus freely employing the fallacy which he elsewhere warns others to avoid, that because a class of plants has not been found, therefore it did not exist at a given geological epoch. But to cut off the possibility of a reply to the position he takes he finally declares that "supposing that sigillarias and stigmarias could really be shown to be cryptogamic plants, and that it could be absolutely demonstrated that neither Coniferæ nor any other dicotyledonous plants existed in the first geological age of land plants, still the theory of progressive development would be untenable, because it would be necessary to show that monocotyledons are inferior in dignity, or, to use a more intelligible expression, are less perfectly formed than dicotyledons. So far is this from being the case that, if exact equality of the two classes were not admitted, it would be a question whether monocotyledons are not the more highly organised of the two; whether palms are not of greater dignity than oaks, and Cerealia than nettles." Teleologic and anthropocentric reasoning like this pervades all the discussions in this work and vitiates the scientific deductions. The elaborate experiment that Dr. Lindley made and described in the first dozen pages of the third volume was obviously animated by the same spirit of uncompromising hostility to the development hypothesis. By showing that the higher types of plants when long immersed in water are earlier decomposed than ferns, conifers, and palms, he thought he had demonstrated that the reason why we find no dicotyledons in the Carboniferous is simply because they had not resisted, and from their nature could not resist, the destructive agencies to be overcome in the process of petrifaction. One could wish that he might behold the four thousand species of fossil dicotyledons now known, and realise how vain had been his experiment as well as all his theorising!

It is such resistance as this, coupled with the power of the Jussiæan method, that has retarded the progress of correct ideas respecting the development of plant life. Systems of classification have been chiefly modelled after those of the early founders. The text books of botany still generally invert the order and begin with the phænogams, although this is doubtless merely intended to facilitate study, and does not at all imply that our leading botanists believe this to have been the order in which plants have developed. This inversion of the order, however, shows how completely the notion of development is ignored in modern botany, and the system throughout rests upon the evidence furnished by the organs of the plants as they are understood. Nevertheless, it is proper to say that at the present time quite a large body of the most thorough students of vegetal embryology and histology, chiefly in Germany, have rejected much of the modern system of botanical classification, and especially that which concerns the position of the gymnosperms. They prove in the most satisfactory manner that these plants constitute a lower type than any of the remaining phanerogams, and they also find that in their reproductive organs they form a more or less natural transition from the cryptogams to the phænogams, between which they place them. This result is most gratifying to the palæo-botanist, for nearly all works on fossil plants give the gymnosperms this position at the base of the phænogamic series, so sagaciously assigned to them by Brongniart. They have been compelled to do this in the face of the prevailing botanical systems, because this is the position which they are found to occupy in the ascending strata of the earth's crust. It is astonishing that botanists could have remained so indifferent to such a weighty fact, and it is certainly most instructive to find the geological record, so long unheeded, confirmed at last by the facts revealed in living plants. There is no evidence that those who have thus confirmed it were in the least influenced by it, since Sachs and Caruel are as silent respecting palæontology as De Candolle or Bentham.

The founders and perfecters of the prevailing system of botanical classification have not been influenced to any marked degree by the idea of development in vegetable life. Few of the earlier ones had ever heard of development, except at least as a visionary theory. This system had become established long before the doctrine of the fixity of species had received a shock, for although Lamarck, himself a botanist, had sown the seed of its ultimate overthrow, still it required half a century for this seed to germinate, and it was during this half century that the Jussiæan system was supplanting the Linnæan and gaining a firm foothold.

Shaking off, for the time being, all fixed allegiance to any system, let us glance for a moment at the lesson which vegetable palæontology now teaches upon the subject of development.

## BACTERIA AND THE CELL THEORY.[*]

PATHOLOGICAL science has always been more or less governed by some dominant idea. At one time it was the blood and fluids of the body; at another the action of the blood vessels; at another that of the nerves, in which men saw the initial stages of morbid change. The autonomy of the cell and the share taken by cell life in pathological processes replaced the older theories, and now the idea of parasitism seems to overshadow all. The cell theory is becoming subordinated to the operation of microbes, and diseased action is coming to be regarded as the expression of the vital resistance of the tissues to the invasion of external organisms. Professor Virchow, in an article entitled "The Strife between Cells and Bacteria" (*Archiv. der Path. Anat.*, Bd. 101, Heft 1), points out that in spite of the modern advances in bacteriology the cell doctrine is by no means extinguished. Indeed every new discovery tends, he thinks, to confirm the truth that the whole work of the body, and all the changes it undergoes in disease, are the result of the special activities of the cells that compose the organism. Each cell may be regarded as an individual, and every discovery that demonstrates the independent activity of the cell strengthens this doctrine. Thus the discovery of the mobility of cells and of the facts of cell migration did not displace the cell theory, as some think, but merely widened its conception. The matter is somewhat different with the new ideas concerning the influence of micro-organisms; and it becomes a question how far the older view of cellular activities will have to be modified by the introduction of the notions of parasitism. Virchow accordingly traces the development of this, the etiological, side of pathology, which he admits had been much neglected. The notion that fungi could produce disease arose out of the discovery by Bassi of the muscardine disease of silkworms in 1835, of the fungus of favus by Schonlein in 1839, and that of thrush by Jul. Vogel in 1841. Some pathologists — notably Henle — generalised upon such scanty facts, and propounded a theory of disease based on parasitism, which went beyond even our present knowledge. Facts, however, accumulated but slowly; for although the life-history of the ordinary fungi was known, that of the large group of schizomycetes was ignored or misinterpreted. Ehrenberg classed bacteria among the infusoria, and their vegetable nature was for long in doubt. Again, in those days there were none of the powerful microscopic appliances now in vogue, no idea of "cultivations," none of the methods of staining which are now employed—for, indeed, the staining reagents were not then discovered. Moreover, the ubiquity of these micro-organisms, their presence in every drop of water or bubble of air, may have been one reason why they were overlooked as causes of disease.

---

[*] From the *Lancet*.

Professor Virchow relates an example of this oversight from his own experience in cholera investigation. In the first fatal cases of the epidemic of 1848 he detected "numerous vibriones" in the intestines, and noted the absence of any such foreign matter in the blood. He found in choleraic evacuations "vibriones and ciliated monads," but could determine no special forms, and concluded that their presence was due to decomposition. It is possible, he remarks, that these "infusoria" were identical with common bacilli, but twenty years later he found, in a case of arsenical poisoning with choleraic symptoms, that the large intestine contained "masses of bacteridia and vibrios corresponding with those described by Klob and others as cholera fungi." In 1868 he wrote to the effect that, although the minuteness of such organisms rendered their differentiation difficult, he did not despair that some day a specific form of vibrio in cholera would be found by experimental research. Therefore he would not abandon the notion of there being a cholera fungus, and of the cholera miasm being a ferment; and, looking to the present stage of inquiry respecting the comma bacillus, he holds that the question is still unsolved, even in spite of improved instruments and methods.

The idea that infective diseases are due to the presence of micro-organisms remained hypothetical until the discovery of the anthrax bacillus by Pollender, Davaine, and Brauell, that of the micrococci of variola and vaccinia by Keber, and of the spirillum of relapsing fever by Obermeir came to supply definite facts as to the presence of microbes in the blood. Yet how much remains to be done, even in the first stage of this etiological research—viz., the proof of the presence of micro-organisms! Such proof is wanting in the case of a large number—and these the commonest forms—of infectious and contagious diseases. For the mere discovery of the presence of a microbe is of slight gain either to pathology or treatment. Is relapsing fever, asks Virchow, better understood or treated since the discovery of the spirillum? Of what influence has the discovery of micrococci been upon the doctrines of small-pox and vaccination? Had it not been for Pasteur's application of the principle of attenuation of virus to the practice of protective inoculation, the sole practical outcome would have been, that of Lister, which, it must be remembered, was the result of a stroke of genius, and not of the demonstration of actual fact. Nevertheless, micro-organisms occupy the field. They occupy the thoughts and fill the dreams of many old and all young physicians. The part played by cells is forgotten, or deliberately ignored, and in evidence thereof Virchow quotes a passage from a Paris journal in which it is declared that the republic of cells has been vanquished by the forces of parasitism. No wonder that the great founder of cellular pathology should cry "Poor little cells! Many a man with his 'Abbe-Zeiss' seeks to render them invisible, and to bring into view only the stained microbe. Yet they are there, and can wait; their time will come again when physicians have finished the task of filling up the lacunæ of botanical knowledge. Then the cell will once more take up its position in the front rank of scientific and practical interest."

If, however, cell life should become again the foundation of morbid processes, it will be more or less under the influence of the new doctrines. For after a parasite has been discovered, and its mode of life ascertained, there remains the problem how it excites disease. When Koch discovered the tubercle bacillus, many said that all the careful labour of former days upon phthisis had been thrown away. Phthisis was a unity, for the bacillus was at its root. Pulmonary tuberculosis was identical with caseous hepatisation, glandular tuberculosis with scrofula, and so on. But in a short time it was found that this unity could not be maintained, and pulmonary phthisis remains what it was—a process of varied origin, sometimes the outcome of mere inflammation, sometimes of specific tubercle. He who would understand it aright must learn something more than how to stain bacilli. So little light has the discovery thrown on phthisis that even the upholders of bacillary phthisis have to fall back upon the notions of predisposition and immunity. The knowledge of a bacillus may be necessary for a full comprehension of the origin of a morbid change, but it does not explain the lesion nor render its examination superfluous. So is it with leprosy. The discovery of the bacillus lepræ excluded a large number of other possible explanations, but made no positive advance in the diagnosis, prognosis, or cure of the disease, and will make no advance until by the application of the older knowledge of the local affections of leprosy to the bacillus we gain some insight into the relations between the two. That relation may be expressed in the terms of the title given by Virchow to his paper. We may conceive a state of war between the microscopic cell elements of the body and the microphytes. Both cell and microphyte are endowed each with its own life and powers. Which is the aggressor? What excites its attack? Does the other combatant resist, and, if so, by what means? Which of the two is vanquished in the struggle? These are questions to be answered. In olden time disease was regarded as a struggle. The definition of Schultz-Schultzenstein made it a struggle of life with death; but it is the living thing that struggles, and not life, while death is no active opponent—it is merely a negation. Schonlein was nearer the truth in his statement that the living body contends against cosmic and telluric assaults. At present we know more of the properties and activities of cells than we do of these vegetable parasites, but knowledge of the latter, and of their product — ptomaines — grows day by day, with clearer evidence that the nature of their action upon the cells of the body is a chemical one. The near future will have to determine what is the nature of the resistance offered to this agency by the living cell; and already the researches of Metschnikoff have thrown some light upon this, showing how bacterial organisms can be taken up and destroyed by the cells of the animal body. Thus Virchow predicts we shall see inquiry enter once more within the domain of cellular pathology. The search for the cause of diseased action will lead to the further question as to how that cause operates, and to answer this our knowledge of cell life will need to be expanded. If, then, the modern pathologist is engaged in detecting and describing bacterial organisms, he will so much advance our knowledge of disease; but he cannot, in this limited view, give that fulness to knowledge which will embrace not only the causative agent, but the organism acted upon; not merely the parasite, but the host; not the bacterium only, but the cell that it attacks. We need to be reminded of such things, if only to teach us a little humility, and to prevent us falling into errors which would do much to bar real progress in knowledge.

## ON THE COLOUR CORRECTION OF DOUBLE OBJECTIVES.*

By CHARLES S. HASTINGS.

### I.—Review of Attempted Methods.

IF we call the focal length of two thin lenses in contact P, one of the lenses being made of a material with indices of refraction $n$, and the other with indices indicated by $n'$, we may write—

$$\frac{1}{P} = \phi = (n-1)A + (n'-1)B \quad \dots\dots\dots\dots(1)$$

where A equals the sum of the curvatures of the two surfaces bounding one lens, and B the corresponding sum for the other.

In order that this system may be achromatic, it is necessary that P or $\phi$ should be invariable with $n$ or $n'$, or, in other words, that the equations—

$$\frac{d\phi}{dn} = O = A + \frac{dn'}{dn}B \quad \dots\dots\dots\dots\dots\dots(2)$$

$$A = -\frac{dn'}{dn}B \quad \dots\dots\dots\dots\dots\dots\dots\dots(3$$

should be satisfied. Unfortunately, this is in practice impossible, because at present no two varieties of glass are known in which $\frac{dn'}{dn}$ is constant. On the contrary, this coefficient is itself a function of $n$, and has an infinite number of values, all included in practical cases, however, within limits nearly approached. Thus, since the last equations cannot be satisfied for all values of $n$, the problem is reduced to finding that value of $\frac{dn'}{dn}$, which substituted in (3) will make the combination the most advantageous one.

The first efforts to find a solution of this problem were attended by one of the most brilliant discoveries in physical optics. Only in objectives of considerable size does the question become of great importance, and as Fraunhofer was the first to attempt such objectives, so he was first confronted with the problem. To solve it, he performed an elaborate series of experiments on the optical properties of various glasses, during which he discovered the lines in the solar and certain stellar spectra universally known by his name. Moreover, as it was evident that the accepted value of $\frac{dn^1}{dn}$ should depend upon the relative intensity of lights of different refrangibilities, he made a photometric determination of the brightness of the various parts of the solar spectrum. With data thus derived, his theoretical method of determining the best value of the coefficient $\frac{dn^1}{dn}$ was to deduce various values by observation, multiply each value so obtained by the relative brightness of the corresponding region of the spectrum, and divide the sum of these products by the sum of the numbers denoting the brightnesses. For example, if ${}^{n}a$, ${}^{n}\beta$, ${}^{n}\gamma$, &c., are the indices of refraction for the first medium corresponding to the Fraunhofer lines $a$, $\beta$, $\gamma$, &c., ${}^{n'}a$, ${}^{n'}\beta$, ${}^{n'}\gamma$, &c., the corresponding quantities for the second medium, and $q_1$, $q_2$, $q_3$, &c., are the relative quantities of light contained in the solar spectrum between the lines $a\beta$, $\beta\gamma$, &c., then the accepted value of the co-efficient is given by the equation—

$$\frac{dn'}{dn} = \frac{q_1 \frac{{}^{n'}\beta - {}^{n'}a}{{}^{n}\beta - {}^{n}a} + q_2 \frac{{}^{n'}\gamma - {}^{n'}\beta}{{}^{n}\gamma - {}^{n}\beta} + \&c.}{q_1 + q_2 + \&c.}$$

Fraunhofer found, however, that for a combination of crown and flint glass this method always gives too large a value for $\frac{dn'}{dn}$—that is to say, that an objective so constructed would be notably under-corrected. Nor is it difficult to recognise that the theory is imperfect, for it implies that light of all refrangibilities is of value in the formation of the image exactly in proportion to its intensity, whereas in reality light of the extremes of refrangibility, instead of assisting in defining an image, is absolutely harmful. Fraunhofer was driven, therefore, to a purely empirical determination of the quantity under discussion, and from his time to the present the only way for an optician to determine the relative foci of the two components of an achromatic objective, is by a laborious process of altering the curves, and testing the result, until the outstanding colour, about the image of a bright star, is such as *experience* has shown is attended with good definition. A few of the more scientific opticians determine the coefficient by means of prisms instead of lenses, and thus by a knowledge of the mathematical relations involved, save a great deal of manual labour. Still, even in the case where a pair of prisms combined to form a *diasporometer* is used, instead of a pair of lenses, the accepted value of the coefficient depends upon an exercise of the judgment alone, and hence this process yields no unambiguous solution.

### II. A Theoretical Solution.

In order to investigate the best theoretical value for the coefficient $\frac{dn'}{dn}$, we may begin by expressing $n'$ either directly or indirectly as a function of $n$. The most naturally suggested course is to express each as a function of the wave-length of light according to Cauchy's well-known formula; but not only is the labour of computing the constants for the necessary three terms of such a formula great, but the accuracy of the expressions thus obtained is very inconsiderable. In another article*, however, I have shown that $n^1$ may be expressed for all cases of practical importance, as a function of $n$ by a simple trinomial of the second degree, so that the residuals are smaller than the errors of observation, except in cases where very extraordinary accuracy is attained. We have thus—

$$n^1 = a + \beta n + \gamma n^2;$$

and the equations above become—

$$\frac{1}{P} = \phi = (n-1)A + (a - 1 + \beta n + \gamma n^2)B \,..(1')$$

$$\frac{dy}{dn} = O = A + (\beta + 2\gamma n)B \dots\dots\dots\dots\dots(2')$$

$$A = -B(\beta + 2\gamma n) \dots\dots\dots\dots\dots\dots(3')$$

---

* From the *American Journal of Science*. Third series, Vol. XXIII. No. 135.—March, 1882.

* *American Journal of Science*, Vol. XVIII. p. 429 1879. See also ENGLISH MECHANIC, p. 447.

The problem is to determine the particular value of $n$, which can be most advantageously substituted in the last equation. This value will be designated as $n_o$, and the corresponding focal distance as $P_o$.

To accomplish this solution we must first find a criterion of excellence in an objective. This we may easily do, after defining the sense in which we here use certain certain terms, as follows:—

Light, for the purpose of this investigation, is defined as that form of radiant energy which affects the retina. Its quantity is measured, not by the value of the energy, but by the physiological effect which it is capable of producing. The *intensity of light of refrangibility*, $n$, is measured by the quantity of light contained between the refrangibilities, $n$ and $n + dn$, divided by $dn$. Thus, if $q_n$ equals the quantity of light so defined, and $\iota_n$ its intensity, then—

$$q_n = \iota_n \, dn.$$

In what follows we shall consider only such light as is given out by a very hot solid body. This light is composite, and contains light of all refrangibilities from a little less than that of the Fraunhofer line A, to practically a little more than that of the line H. We let $n_r$ and $n_v$ represent these limits of refrangibility. Then if Q is the total amount of light falling upon a given area—*e.g.*, upon an objective—we have evidently—

$$Q = \Sigma q = \int_{n_r}^{n_r} \iota \, dn$$

In this expression $\iota$ is an unknown function of $n$; but we know enough of the properties of this function for the present purpose.

A perfect objective would concentrate *all* the light incident upon it from a distant point in its axis to a very small circular area in the focal plane, which area would be constant for all telescopes of the same angular aperture. The most perfect attainable objective then would be that which concentrates the greatest attainable amount of light within this area. To investigate the conditions which must be satisfied to this end, we must determine the amount of light falling within a small circular area $\sigma$ at $P_o$, the radius of which we will set as $a$ tan. $\frac{1}{2}$ $\alpha$, where $\alpha$ is the angular aperture of the objective. It is evident that all the light of such refrangibilities as substituted in ($1^1$) would yield values of P contained between $P_o - a$ and $P_o + a$ would fall within the area $\sigma$. These limiting refrangibilities shall be denoted by $n_{-a}$ and $n_{+a}$. Only a portion of the light of refrangibilities less than $n_{-a}$ and greater than $n_{+a}$, however falls upon this area, the amount of light for the refrangibility $n$ being clearly—

$$q_n \frac{a^2}{(P_o - P_n)^2};$$

hence the total quantity of light falling upon $\sigma$ would be equal to the sum of the three integrals, the first taken from the extreme red up to $n_{-a}$; the second from $n_{-a}$ up to $n_{+a}$, and the third from this last up to the extreme violet—that is, if $q$ be this quantity—

$$q = a^2 \int_{n_r}^{n_{-a}} \iota_n \frac{dn}{(P_o - P_n)^2} + \int_{n_{-a}}^{n_{+a}} \iota_n \, dn$$
$$+ a^2 \int_{n_{+a}}^{n_a} \iota_n \frac{dn}{(P_o - P_n)^2}.$$

To find the value of $n_o$, which will render the last expression a maximum, it is necessary to find the first derivative of the function with respect to $n_o$ and set it equal to zero. Remembering that $\frac{dP_o}{dn_o} = 0$, we see that $P_n$, $n_{-a}$, and $n_{+a}$ are the only quantities dependent upon $n_o$; hence we obtain by differentiation under the signs of integration.

$$\frac{dq}{dn_o} = 0 = -2a^2 \int_{n_r}^{n_{-a}} \frac{\iota_n \, dn}{(P_o - P_n)^3} \frac{dP_n}{dn_o}$$
$$+ a^2 \frac{\iota_{n-a}}{(P_o - P_{n-a})^2}$$
$$+ \iota_{n+a} - \iota_{n-a} - 2a^2 \int_{n_{+a}}^{n_r} \frac{\iota n \, dn}{(P_o - P_n)^3} \frac{dP_n}{dn_o}$$
$$- a^2 \frac{\iota_{n+a}}{(P_o - P_{n+a})^2}$$

But from the definition of the quantities $n_{-a}$ and $n_{+a}$ we have—

$$(P_o - P_{n-a})^2 = (P_o - P_{n+a})^2 = a^2.$$

Hence, the value of $\frac{dq}{dn_o}$ reduces to minus the product of $2a^2$ into the sum of two definite integrals $dn_o$, and the problem becomes simply the determination of the value of $n_o$, which will cause this sum to vanish, as since $\frac{dP_n}{dn_o} \cdot \frac{1}{(P_o - P_n)^3}$ must have opposite signs in the two integrals because $\frac{dP_o}{dn_o} = 0$, that value which will make the two integrals equal. If both $\iota_n$ and $P_n$ were symmetrical with respect to some one value of $n$, that value would evidently answer the condition: otherwise it is necessary to know the function $\iota_n$.

It would be easy to find a transcendental function which would express empirically the photometric observations of Fraunhofer, or the more recent and elaborate ones of Vierordt; but a simple consideration of the physical limitations of the problem will enable us to dispense with this operation. Hitherto, we have made no restrictions as to the value of $\sigma$. Let us now suppose that $\sigma$ is so small that it may be regarded as the image of a star, then $a$ is small, and since $\frac{dP_o}{dn_o} = 0$, $P_n$ may be regarded as symmetrical with respect to $n_o$ for values not differing largely from $P_o$. Again, for white light $\iota_n$ is shown by the photometric observations above named to have a single maximum corresponding to a certain value of $n$, which we will designate as $n_1$, and consequently may be regarded as a symmetrical function of $n$ in the region of this maximum. Finally, $\frac{dP_n}{dn_o}$ is never large in practical cases between the limits $n_r$ and $n_o$, while $P_0 - P_n$ increases continuously in numerical value toward these limits. If, then, we set $n_o = n_1$ the two definite integrals become sensibly equal, and $q$ is a maximum.

The value $n_1$ corresponds to light of a refrangibility greater than that of the Fraunhofer line D, and less than that of E; nearer, however, to the former. The only prominent Fraunhofer line readily seen with a crown-glass prism of moderate dimensions in this region is that of wave-length 5614. This I will assume as defining $n_o$, and consequently the ratio of A to B in (3). In all substances practically useful in telescope making, $\gamma$ of (2′) is positive, therefore $P_o$ is a minimum.

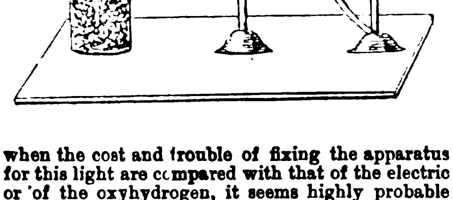
The reason given above is evidently applicable to all forms of radiation transmitted by the lens system, if appropriate definitions of $q$ and $\iota$ are given, and $\iota$ possesses a single maximal value. For instance, in the case of radiant energy, pure and simple, $n_o$ should nearly equal $n_r$ (lenses of glass); and for a photographic objective where silver salts are to be acted upon $n_o$ should be nearly equal to $n_g$.

(*To be continued.*)

## THE NITROUS OXIDE AND CARBON-DISULPHIDE LIGHT.*

By Wm. Thos. Jackman, M.R.C.S., &c.

THE light obtained by burning a mixture of nitrous oxide gas and the vapour of carbon disulphide is well known to be very powerful for photographic purposes. It is of an intensely blue colour, and very active in photographic-chemical properties, being, according to Stein, twice as powerful as that of the oxyhydrogen flame, and three times as powerful as that of the electric lamp. This able scientist points out that when in full power it illuminates a larger surface than the same sized flame of other artificial sources. Moreover, when the cost and trouble of fixing the apparatus for this light are compared with that of the electric or of the oxyhydrogen, it seems highly probable that this form of artificial light will be more extensively used than it is at present. The want of a reliable, cheap, and uncumbersome artificial light has long been felt by photographers; hence I am emboldened to draw attention to this source, and explain shortly the apparatus required for its use, and refer to a few of the experiments which have been made with it, hoping thereby to encourage its more general trial in the art of photography. An ingenious apparatus for the mixing and burning of the nitrous oxide and carbon disulphide vapour has been invented by Delachanal and Mermet, of Paris, by which a constant light can be obtained, and the danger of an explosion obviated, for it must be borne in mind that carbon disulphide vapour is very explosive under certain conditions. The apparatus consists of a double-necked flask of about 500 c.c. contents, which is filled with pieces of sponge or pumice, saturated with the vapour of carbon disulphide. Into one mouth, A, a bent tube is fixed, through which the nitrous oxide gas passes into the flask. A second bent tube is fixed into the other mouth of the flask; this passes into a wider tube of metal, B, 20 c.m. long, which is tightly filled with iron filings, the object of this being to prevent the flame passing back into the explosive vapour contained in the flask. After passing through this tube, B, the mixture of nitrous oxide and carbon disulphide is led by means of an indiarubber tube to a modified Bunsen's burner. This burner has neither the usual opening for the admission of air nor the arrangement for regulating the quantity of gas passing through it. The nitrous oxide enters the flask through A, and after mixing with the vapour of the carbon disulphide in the flask passes through B to the burner, where it can be ignited with safety, and with the production of a very blue flame. The size of this flame depends upon the dimensions of the apparatus. The amount of the mixed gasses to be burnt can be regulated by a stopcock placed between the tube B and the Bunsen burner. E. Sell, of Berlin, produced, a few years since, some excellent photographs with this light, which were exposed a shorter time than when using the electric or magnesium light, and were in every way more perfect. Riche and Bardy, of Paris, also made extensive experiments with this light, and proved it to be twice as powerful as the magnesium, and three times as powerful as the limelight. They further showed that the photo-chemical power of the light was due to the blue flame of the sulphur in the combination. Oxygen may be used instead of nitrous oxide gas, but the latter is recommended as being safer.



## RED PRINTS FOR DRAUGHTSMEN.*

AN innumerable quantity of red photographs are made daily in the city of New York. These red prints are termed silver prints, and although they, in reality, do not deserve to be called silver prints, *par excellence*, there is a certain reason or excuse for that generally adopted name. Hardwich's theory of substitution—that is, gold substituting the silver of the photograph in the toning process, does not find any application here, as the prints in question are simply silver proofs, fixed, without being toned, in a pure and plain solution of hyposulphite of soda, washed and dried. A majority of the illustrations of our daily newspapers, trade journals, price lists, and various other publications, when printed on the ordinary press from relief plates or zinc etchings, have for a base the photographic silver, or red prints. Such prints, taken from the ordinary negatives, are placed in the hands of a draughtsman, who reduces the photographic half tone, or stipple—in fact, breaks up the original photograph into a system of lines, destroying its original character altogether. The photograph having so far served the purpose of being a sketch to the finished picture is now removed from the paper. A strong solution of bichloride of mercury is poured over it, and in the manner of the so-called magic photographs, the silver deposit on the paper is bleached out, leaving visible only the India ink work upon a white ground.

Such pictures are, or ought to be, a correct representation in line manner of the photograph employed. In portraits the likeness can be kept well, and in landscapes, in machinery, and other inanimate objects, the most intricate details can be rendered sharp and distinct as in the original photograph.

The drawing in its present condition is handed now again to the photographer, who reproduces from it a negative of extremely strong intensity, fit to make from it a relief plate, or to print it on a bichromated albumen or asphaltum film upon a zinc plate, preparatory to the etching process.

Photographs for red prints are mostly always enlargements of the originals in the proportion of one to three. By reducing the drawing afterwards to the original size, the lines are rendered extremely sharp and delicate. Etchings and relief plates managed in this manner are frequently of a beauty equal to any well executed wood engraving.

The making of red prints for the engraver or draughtsman, simple as it may appear, has its difficulties, as well as any other photographic process. The tone of the print is of great importance; if inclined to be black, or when printed too deep, the draughtsman is unable to see the ink lines, especially when very fine. The negative must also be of a certain quality; all details must be visible, and great contrasts between light and shade must be avoided; still the plate must be able to give a well-defined and somewhat brilliant print. Negatives for red prints, which are mostly made on collodion, are somewhat over-exposed and slightly intensified. Ordinary Rives paper is used for printing, salted with chloride of ammonium or barium, from 10 to 30 grains to the ounce of water. Citric acid, the same quantity as the chloride, may be added to the salting bath, or the salted paper, when dried, may be floated for a minute, before silvering, upon an acid solution of the same strength. The strength of the silver should be regulated according to the strength of the salting bath; weak solutions are, however, preferable. After the proof has been printed to the desired depth, it is washed in water acidulated with citric acid, and after all acidity has been washed away, fixed in a fresh hyposulphite-of-soda solution, 1·8. Organic matter, like gelatine or boiled starch, in the salting bath, assists in keeping the red colour.

---

* From the *Photographic News.*

* By C. E., in the *Photographic Times.*

A brick-red or a muddy yellowish tone is probably caused by too strong a silver solution or impure hypo. The quality of the negative has as much to do with a good tone of the print as in any other process. The washing of the print must be done quickly and thoroughly. Hypo in the print prevents the perfect bleaching of the print with mercury; too much washing softens the paper and makes its surface woolly, hence the addition of gelatine or starch is advisable, also to impart strength to the paper. The red tone of the print is of great importance; it assists greatly the engraver's work. The fine lines he draws upon the photograph are more distinct and more visible to him than when made upon a bluish-black ground. There is a great demand for silver prints in the engraving district of New York, and when they are made in the manner described, or by a similar process, they are always satisfactory to the engraver. These prints find a practical application.

How to obtain beautiful and decided red tones has been described repeatedly. The methods with bichromate, grape sugar, and silver development, and many others, give splendid results, and are highly interesting to the student as well as the practitioner, but neither of them has gained such a popularity as the simple so-called silver print.

## THE DYEING OF FEATHERS.

THE *Teinturier Pratique* remarks that the dyeing of feathers (like that of tissues) requires two operations, scouring and dyeing.

*Scouring.*—This operation is intended to remove from the feathers the fatty substances and impurities which they may contain. For that purpose the feathers are steeped for some hours in benzine or mineral essence, and are then exposed to the air. When dry they are carefully soaped in a hot bath of Marseilles soap, being afterwards rinsed and dyed.

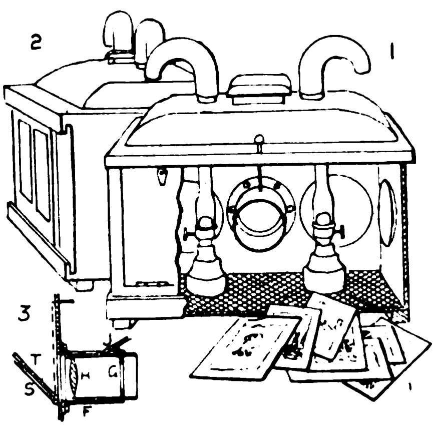
*Bleaching.*—For white feathers the soaping with a hot bath is renewed two or three times. Then rinsing follows, and afterwards azuring in a bath mordanted with a little sulphuric acid, and containing a small quantity of aniline voilet or aniline blue. The feathers are rinsed, passed through a solution of starch, vaporised, and curled.

*Dyeing in Black.*—The feathers are plunged after scouring into a bath of sulphate of iron (green copperas) at 10 or 15 deg. B. They are let soak for two or three days in this bath, then washed and passed in a hot bath of Marseilles soap. The feathers are rinsed and are steeped for forty-eight hours in a solution of tannin at 5 or 6 deg. B. After being again rinsed they are replunged for twelve or eighteen hours into the bath of sulphate of iron, and then washed. Finally they are dyed at 158 deg. to 167 deg. Fahrenheit in a bath containing the quantity of logwood necessary to obtain the shade required. They are then washed and passed through a cold soap bath, after which they are starched, dried, vaporised, and curled.

*Dyeing in Violet, Blue, Green, and Aniline Pink.*—Into a bath of water at 122deg. or 131deg. Fahrenheit, and mordanted with a little sulphuric acid or tartaric acid, there is placed the quantity of colouring substance necessary for the depth of shade required. When it is dissolved the feathers are plunged into it, and are constantly manipulated till dark enough in colour. They are carefully rinsed, and are passed into a light starch bath and dried. They are shaken to remove the excess of starch, then vaporised and curled.

## A REFLECTING MAGIC LANTERN.

A MAGIC-LANTERN which can be used for showing opaque objects has been recently patented by Messrs. H. and G. Davenport, of Somerville, Philadelphia, U.S.A., and is thus described by the *Scientific American*:—On the inside of each end of the front, and on the inside of each end of the box, is a concave reflector; these are so placed as to concentrate the light upon the picture at the centre of the back of the box. In a tube, F, projecting inward from the front, between the mirrors, is arranged a sliding tube, C, holding a convex lens, H. This tube is moved for focussing by means of a rod, J, extending up to the top of the back of the box. In the box two lamps or other lights—such as calcium or electric—are placed between the mirrors at each end, as shown in Fig. 1. Above each light is placed a detachable funnel. The top of the box is curved and the under side is polished to reflect the rays of light. In the top is a ventilating opening provided with a hood to permit the hot air to escape; the supply of air is admitted through the perforatted bottom. The pictures are held in a sliding apparatus moving between two longitudinal grooves (Fig. 2) secured on the outside of the back of the box, and having two apertures, which can be closed by hinged doors. The pictures are held in place by closing the doors, and can be shifted to appear in an opening in the back of the box. The light from the lamps is reflected by the mirrors upon the picture, and from the same through the lens upon a screen or wall. By means of a mirror, T, on a door, S, hinged to the front of the box below or at either side of the tube, the light can be reflected upon any desired surface. Any opaque object, such as a photograph, chromo, or drawing, can easily be reflected upon the screen in any desired size, all parts being clear and distinct. The pictures do not become heated sufficiently to injure them, and may remain in the apparatus for hours without being destroyed.



## USEFUL AND SCIENTIFIC NOTES.

**Effects of Lightning.**—At a recent meeting of the Berlin Verein für Innere Medicin, Dr. Liman described the changes present in the bodies of two men who had been killed by lightning when taking shelter under the trees of the Thiergarten. In the one subject, the hair over the left temple was singed, and the skin from the left ear to the shoulder-blade was discoloured a brownish-red, the chest and abdomen being covered with red and white streaks. Reference was made to the dendritic figures described in many cases, and attributed often to impressions of twigs, leaves, &c. (a specimen of which was figured in our columns not very long ago), and in this body there was a figure which could be compared to a palm-leaf, but which was undoubtedly due to the contact of the folds of the shirt. The parts thus pressed upon remained white, the surrounding skin being reddened. The apex of the heart was the seat of an irregular cavity, which communicated with both ventricles; evidently the lightning stroke had caused rupture of the organ. In the other case, the skin and hair were simply excoriated and singed, and numerous ecchymoses occurred beneath the serous layers of the pericardium and pleura; the lungs were much congested. Here death was evidently due to asphyxia. Dr. Liman mentioned, and Professor Leyden confirmed, the fact that death by lightning is occasionally accompanied by rupture of internal organs, as the brain and liver.

A PIECE of amber weighing 8lb. is at present being exhibited in the Mark Museum at Dantzig, for which the owner has refused £1,500. It is probably the largest piece in the world without blemish. Frederick the Great, more than a century ago, paid the same sum for a piece weighing 13lb., which is preserved in the mineralogical museum at Berlin, but it has gaps and cavities. Two beautiful pieces of work in amber are also to be seen in Berlin. One is a flute, which also was an acquisition of Frederick the Great. The other is a complete tobacco-pipe, belonging to Frederic William III., the father of the present Emperor; it bears an admirably carved likeness of that monarch.

A FORTNIGHTLY journal called the *Linguist* is to be published, written in five languages—viz., English, French, Spanish, Italian, and German.

## SCIENTIFIC NEWS.

THE death is announced of Prof. Worsaae, the distinguished Danish archæologist.

Mr. William Gough Birchby, the hon. sec. of the Vegetarian Society, died recently at the early age of 35. He was head-master of the New Jerusalem Schools, Salford, a Swedenborgian, and a Fellow of the Royal Meteorological Society.

An international cookery and food exhibition is to be held at the Westminster Aquarium in December. The exhibition will comprise 150 classes, and besides gold, silver, and bronze medals, there will be "valuable money prizes."

Prof. Simon Newcomb is visiting Stockholm as the guest of Prof. Gylden, the astronomer-royal of Sweden. He will proceed to Pulkowa in order to view the great Russian observatory.

The fifty-eighth meeting of the German Association of Naturalists and Physicians will meet at Strasburg on Sept. 17.

The American Association for the Advancement of Science is in session at date of publication, and it is expected that some useful papers will be read, especially in Section D, in which a discussion will take place on the best method of teaching mechanical engineering.

In the aquarium a the Inventions there are now some specimens of the black bass, which is indigenous to the rivers and lakes of Canada and the United States. We believe it has been proposed to introduce the black bass into our waters, but anglers object on account of the voracity of the fish, although they provide excellent sport. The introduction of the American catfish is also objected to on the same grounds; but according to Professor S. F. Baird, the United States commissioner of Fish and Fisheries, the catfish does not molest other fish, and does not exclusively prefer live food. The National Fish Culture Association has made some investigations, and at present cannot disprove Prof. Baird's assertions; but judging by the appearance of the specimens in the tank at the Inventions, the catfish should prove to be a useful addition to our rivers, both as a food fish and as sport for the angler.

In connection with "fish," a curious story comes from Vadö, in East Finmarken. Dr. G. A. Guldberg, of the University of Christiania, says that the fishery of rorquals or fin-whales continues to be turned to good account for scientific purposes, and that considerable quantities of the flesh of the whales killed at Vadö have been "tinned" for consumption in Catholic countries—a statement which has caused some remarks to be made about the zoology of the Church. In spite of Prof. Flower's monograph of the whale, not much is known as to the suitability of its flesh for the food of man; but the blue whale is known to feed on a small crustacean, and the absence of the *Balænoptera Sibbaldii* from the coast of Norway is attributed to a scarce food supply. Rudolphi's whale, *B. borealis*, is the "fish" that is tinned, and that has been caught in large numbers.

In connection with the British Association, which meets at Aberdeen on Sept. 9th, it is interesting to learn from the *Scotsman*, which gives an account of the "arrangements," that "Her Majesty the Queen had agreed to drive a party of excursionists round by Balmoral." The guarantee fund now amounts to over £2,505, and the number of "excursions" should satisfy the most ardent follower of the Association for the Advancement of Science.

The Essex Field Club has recently published a paper by Mr. T. V. Holmes, F.G.S., in which he reviews the evidence as to the antiquity of the human skeleton found a short time ago at the Tilbury Dock excavations, which was described by Sir R. Owen in his recent work on the "Antiquity of Man." The skeleton appears to have been found at a depth of 34½ft., nearly 2ft. below the upper surface of the sand, and is described by Sir Richard as that of a robust man who had attained old age, and the thickness and strength of whose thighbone indicated power and frequency of locomotion. The forehead is low and narrow, matched by low Australian and Andamanese skulls; and if the skeleton is, as Sir R. Owen considers, the first unquestionably palæolithic bones of man yet discovered, the conclusions which he draws, with the eloquence and clearness that still, as always, characterise whatever he writes, are fully justified. Mr. Holmes, however, points out that, as the illustrious and venerable naturalist has never visited the docks himself, he does not appreciate the difference of age between those older alluvial deposits of the Thames Valley in which Mr. Worthington Smith has found palæolithic implements and the newer alluvium of Tilbury.

The original MS. of the lectures delivered by William Harvey before the Royal College of Physicians in 1616 and the following years, which were discovered a few years ago in the British Museum, are to be published in a facsimile reproduction, together with an interleaved transcript made by Mr. J. S. Scott, of the MSS. department of the Museum. The work will be issued by Messrs. Churchill, probably in the spring of next year.

With reference to the article on "Electricity and Dust," which appeared on p. 377, it has been pointed out by a German paper that a similar experiment to that of Prof. Lodge was described by C. F. Guitard, of London, in the *Mechanics' Magazine* for Nov. 2, 1850. The following is an extract:—"Some time since, in experimentalising on the electric state of the atmosphere, I employed for that purpose a large glass cylinder, about 18in. high and 9in. diameter, open at bottom and having a neck at top. In placing the lower end of this cylinder in water the more perfectly to exclude the air, and allowing small quantities of tobacco smoke to enter the neck at top, the smoke, after assuming various actions, according to, probably, the hygrometric state of the atmosphere, would gradually spread itself into a cloud filling the cylinder, and at length, as successive portions came in contact with the sides of the cylinder, condense. Sometimes half an hour would elapse before this effect took place. It now struck me that if I brought a wire from an electrifying machine into the neck of the cylinder, the air would immediately become charged with electricity, which would cause each portion of the smoke to fly to the sides of the cylinder, and that thus more rapid condensation would take place. The effect produced was perfectly magical. The slightest turn of a small electrifying machine produced immediate condensation. It was astonishing to see how small a quantity of electricity produced a most powerful effect. I am not aware that attention has ever been drawn to this subject; and the question will probably arise, Has electricity anything to do with the condensation of steam in the condenser?"

Prof. S. P. Thompson calls attention to the neglect of the means which mechanical science has provided for the automatic extinction of fires. He alludes to the "sprinklers or distributors of water which are now to be found fitted up in many mills and warehouses in Lancashire and the North, and which are almost universal in New England and other parts of the United States. This may seem remarkable, yet it is not to me so remarkable as the fact that nine out of every ten intelligent persons to whom I have spoken on the subject do not even know what an automatic sprinkler is, and have not the faintest conception in what way a system of sprinklers can be arranged in a factory so that in whatever part a fire may break out, there the water will be automatically discharged without waiting for any human being to notice the outbreak."

At the meeting of the Leicester branch of the Amalgamated Society of Railway Servants, held last week, attention was drawn to the fact that at some recent inquests unexpected questions were asked and evidence given which seriously implicated certain railway servants, and the opinion was expressed that an officer of the society should attend and watch the case in the interests of the society. The Binegar accident was referred to, and after Mr. Stretton had explained the circumstances he was requested to communicate with the signalman's solicitors, and render assistance in defending him.

The report of the Trinity House Committee on lighthouse illuminants contains the following conclusions:—(1.) The electric light is the most penetrative of the three luminaries in all conditions of the atmosphere, fog included. It, however, is more costly than either gas or oil, and its dazzling effect in clear weather renders it unsuitable for general adoption around the coast. (2.) The gas and the oil lights are practically equal; but the latter system is considerably cheaper, and is simpler and more convenient than the former. The committee, therefore, recommend that "for the ordinary necessities of lighthouse illumination mineral oil is the most suitable and economical illuminant, and that for salient headlands, important landfalls, and places where a very powerful light is required, electricity offers the greatest advantages."

With reference to the application of electricity to the working of railways, the second section of the Railway Conference at Brussels reported that, in view of the great progress which had already been made in this respect, they look forward to further improvements; but they made no recommendation. Eventually, however, the second and third sections consulted together, and reported that considerable progress has been realised in the employment of electricity on railways, and that it is probable that further progress will be made, which will largely augment their security, and that it will be desirable, having regard to this question, to ascertain whether preference should be given to electricity or to mechanical appliances, and that this is a question for the future, having regard to the necessities of distance, climate, and the nature of the apparatus, which can only be decided by experience.

The Cunard steamer *Etruria* has made the trip to New York in 6 days 5 hours 31 minutes corrected time from Queenstown—the quickest on record. The average hourly speed was 19 miles, which means that on occasions over 20 was the rate. It is probable that with favourable weather the *Etruria* will also make a quick passage home, and thus put the quickest voyage on her record.

# LETTERS TO THE EDITOR.

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. PASSMORE EDWARDS.

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

## TELESCOPIC POWERS—EQUATORIAL MOUNTING—PHOSPHORESCENCE OF THE SEA.—THE MOTION OF THE SUN IN SPACE—HOME-MADE MICROSCOPES—RAIN-GAUGE—MEASURING THE POWERS OF A MICROSCOPE.

[24665.]—AT the place whence I write I have no means of access to No. 191 of the *Astronomische Nachrichten*, which is quoted in letter 24596 (p. 519) by Mr. Rogers. Hence I am curious to know whether, in addition to the astounding statement that a 3in. object-glass ever bore a power of 550 on Mars! anything is said about the manner in which such (alleged) power was measured?

"Landbird" (query 57257, p. 529) should send to the office for numbers 52, 296, 300, 421, 612, 613, 661, 673, 774, 778, 791, 796, 808, 898, 902, 973, 976, and 979 of the ENGLISH MECHANIC, in which he will find descriptions of very diverse forms of equatorial mounting—all of them, however, of a fairly simple kind, and within the power of construction of any fairly skilful amateur. Descriptions of more elaborate forms of the equatoreal appear in other volumes; but these are of a more costly and complicated character than your correspondent evidently requires.

The familiar phosphorescence in the English Channel, to which the same correspondent refers in query 57269 (p. 530), is produced by the Noctiluca miliaris, one of the protozoa. Why should this not be visible in smooth water? I have seen the sea luminous alike from the pier of an English watering place and the deck of a "Trooper," in the Mediterranean. In every case it is traceable to some lowly form of animal life.

One of those philanthropists who arise at intervals to set the whole world to rights, a gentleman named Tischner, of Leipzig, is circulating in this country a brochure entitled "The Fixed Idea of Astronomical Theory," with a view to show that all the (alleged) blunders of astronomers have their origin in the assumption of the fixity of the sun. Speaking merely for myself, I have always been under the impression that so fair a case had been made out for a motion of translation of the entire Solar system in space in the direction of the constellation Hercules, that such motion was ordinarily referred to in textbooks as an established fact. It is not, however, so much the mere translation of our system bodily in space, as the alleged results of such translation which form the subject matter of the funny little pamphlet before me. Between absolute and relative motion, Herr Tischner seems wholly unable to discriminate. The planets, he asserts, do not describe closed curves, on account of the proper motion of the system of which they form part; but, surely, we, here on earth, at a practically infinite distance from the Universe of Stars, must refer our movements to the centre which dominates them. Let me take a simple illustration. Suppose that Herr Tischner were to travel by railway from Leipzig for an hour, and on starting were to lay his watch, face upwards, on one of the cushions of the carriage, then, in the course of that hour, the end of the minute hand would complete one revolution about the centre of the dial. But, meanwhile, the carriage will have travelled, say, 35 miles on the rails. The whole part of the earth on which those rails are laid will have been carried rather more than 648 miles round the earth's axis by her rotation, and some 66,199 miles in her orbit in common with the whole world, to say nothing of the little journey—or part of it—towards Hercules; so that to be consistent (on Tischnerian principles) we ought strenuously to deny that the curve described by the extremity of the minute hand of our hypothetical watch is a closed curve at all! I have selected this one contention from the pamphlet as a fair illustration of its style of argument. It is wholly needless to discuss what its author says with reference to the non-existence of "centrifugal force," a term never now to be found in the most rudimentary books on mechanics, celestial or terrestrial; or his astonishing notion that the motion of the sun in space causes the precession of the equinoxes! Enough has been said to show in what a muddle an earnest and well-meaning man may involve himself who meddles with what he does not understand. Did Herr Tischner ever hear how the existence of the planet Neptune was not only independently predicated by Adams and Le Verrier; but its very position in the sky pointed out, by the application of that law of gravitation which he asserts to be non-existent?

In thanking Mr. Hippisley (letter 24637, p. 540) for his most courteous offer to send me specimens of microscopic lenses of his own manufacture, I must express my regret that I am precluded from accepting it by the inexorable rule as to my incognito. I gravely question whether it would be possible to define the curve assumed by the surface of a piece of glass melted into a lens in the manner he describes. In point of fact, I should say that it was made up of three or four curves, differing considerably in character.

May I be allowed to refer Mr. Williams (letter 24646, p. 542), to page 339 of Vol. XXXVIII. of this journal?

"Micro." (query 57307, p. 551) presumably wishes to know the magnifying power of his eyepieces with different object-glasses. He may do so with probably sufficient accuracy for his purpose by getting a stage micrometer divided to hundredths, and for high powers, thousandths, of an inch, and a rule divided into 10ths of an inch. The latter is to be placed at a distance of 10in. from, say, the left eye, and the micrometer scale viewed through the microscope with the other eye; by shifting the rule about a little, some of its divisions may be made to correspond with one of those of the stage micrometer, then a simple-division sum will give the power. Thus, suppose that 1·7in. on the rule, as seen with the naked eye, exactly coincides with one of the (magnified) divisions of a hundredth of an inch, then must the microscope magnify 170—and so on.

**A Fellow of the Royal Astronomical Society.**

## THE DAYLIGHT OCCULTATION OF ALDEBARAN.

[24666.]—WHILE sharing Mr. Pearson's desire to bring this correspondence to a close, I feel I cannot do so without pointing out that, notwithstanding the honourable position attained by him in the mathematical tripos of 1848, he fails to grasp the fact that my expression, "different geographical positions," includes differences both of *latitude* and longitude, and thus indicates a knowledge he is so good as to say I ought to possess.

In the concluding paragraph of Mr. Pearson's letter the following passage occurs: "If Mr. Peek is still unconvinced, I have done with him." Convinced of what? I am certainly not convinced that the prediction of the circumstances of an occultation ever can, or ever were intended to, take the place of the observation itself, especially when I remember that the lat. and long. of any station must be accurately known before such prediction can be accurate, whereas the very object in observing the occultation is to deduce the long. from it. Such extreme accuracy is, however, by no means necessary for practical purposes. It is quite sufficient if the time of its occurrence is known within such limits as will allow the observer to be ready at his telescope before the phenomenon takes place.

That there is a necessity for computing the circumstances of occultations at places distant from Greenwich no one for a moment doubts, as it would be sheer waste of time for a traveller to remain at a place where the occultation of a fifth or sixth mag. star takes place in the full blaze of sunlight, and anyone who contributes to the simplification of the computation necessary to ascertain this fact is doing very good work. What I maintain, however, is this: that the results obtained by a partially graphic method cannot be compared, for accuracy, with the results of actual observation when the instrument used is a good telescope, and the time taken by a chronometer, the error of which on local sidereal time is accurately known; the former is theory, the latter is fact.

**C. E. Peek, M.A., F.R.A.S.**

## TELESCOPE POWERS.

[24667.]—With reference to H. Sadler's "contradiction" (letter 24628, p. 539), I beg to say that my authority in stating that Mädler used a 3in. refractor in his observations of Mars in 1830 is to be found in the *Observatory* for September, 1877, p. 180. In a letter on "Drawings of Mars," Mr. W. G. Lettsom there states that Mädler's observations "were taken with a Fraunhofer refractor of only 3in. aperture and 45in. focal length, English measure." I presume the correction now afforded by H. S. is just; if so, I am obliged to him.

My own experience with regard to telescopic powers is that about thirty-five to the inch is as much as can be employed with perfect satisfaction for ordinary purposes. **W. C. Rogers.**

August 24.

## MOTION OF STARS IN THE LINE OF SIGHT.

[24668.]—My attention has just been called to a report which appears in your issue of the 5th of June of a lecture on "The Motion of Stars in the Line of Sight," which was delivered by me to my students in Trinity College. The report omits, however, to mention that many of the facts discussed in this lecture had been taken from a very interesting article which had been published in the *Observatory* for April and May by Mr. E. W. Maunder. I also take this opportunity to say that the change in the direction of the movement of Sirius had been demonstrated by Mr. Huggins's observations alone, and that it was afterwards confirmed and extended by the observations at Greenwich, to which Mr. Maunder has so largely contributed. **Robert S. Ball.**

## LUNAR GLACIATION—TO "F.R.A.S."

[24669.]—I fear the letter I wrote in reply to the inquiry by "F.R.A.S.," on p. 167, April 24, has shared the fate of two other home letters, and been suppressed in the local post-office for the sake of the sixpenny stamp. Government know this partiality of our Babus for any undefaced stamps, and wisely issue envelopes with stamps embossed on them.

If, when run out of such "overland envelopes," we use a common one, and forget to deface the stamp by some means, the result is too often what we see in this case.

We are all hot to educate the native, but omit all training in morality, honesty, and such; the outcome is a race that can quote Shakespeare, drink unlimited "grogs," and curse parents in a way that takes an old Indian's breath away. I hope "F.R.A.S." will write me an ass if I trust to Babu honesty again.

Now, regarding the slow decline of atmosphere on the moon, and its taking place unequally, I should say the decline took place equally, and not in patches or zones, with semi-vacuum between.

Restating the entire case, I should say that the moon has long ago passed through what I call an "erosive era"—such as our earth is in now—where temperature was higher where there was air, and rivers, and seas of water. That gradually the globe cooled, and as it did so, atmosphere became more rare (a phenomena seen to go hand in hand elsewhere, as in Venus and Mars), the result being that this "era of erosion" gave place to one of surfacing by deposit of frozen moisture.

Towards the close of this erosive period, the air would fail as means of transport for aqueous vapour, which latter would only move by diffusion; there would, in fact, be no winds or moving air, or mist, and the permanent deposition of ice on the poles would begin. These ice caps, slowly extending on all sides century after century, would here and there leave deep bays or indentations in the margin (like in the line of the Altai), and due to deeper water, or warm springs, or submarine volcanic vents, such as are common on earth. The moisture raised off the liquid areas would become slowly diffused in the rarefied air, and be unable to travel far or fast, for all over the ice-sheet the temperature would be much lower, and cause its fall as spicula, on and about the margins, thus slowly raising ramparts. As time went on, and glaciation advanced, the horns of the bays would extend, and appear as in Fracastorius or S. Iridium, and at last meet, as in Pitatus, or in Beaumont, &c., where this rampart would be necessarily small, or even incomplete, on the seaside of the lagoon at first. But as glaciation still further advanced, it would increase in height by the deposit of the aqueous vapour off the lagoon, the floor of which (as in Posidonius, &c.) would thus become lowered as the wall rose.

In this way such forms as "Clavius" originated, and after its floor became at last frozen, or the liquid areas restricted to the larger vents that caused it, other vents opening out under the ramparts, would liquefy large areas as lakes that would again raise their own ramparts.

If a first-class heat vent persisted for immense periods, we should not only see complex rings as terraces, but floors deeply depressed, as in Tycho; and at last, ever after the floor or lake surface had frozen over, the moisture still given off by such orifice would slowly pile, and form the vast central cones that are such conspicuous features in these deep and terraced craters.

They would also mark not only the period about which water, as liquid, ceased to exist on the lunar surface, but also of air, as diffusion of aqueous vapour ended.

Thus, during the formation of a huge polar ice cap, covered by these circular forms, and bounded by irregular promontories and bays, the moisture raised in the attenuated air would slowly become diffused and fall on or near the margins of the seas, bays, or inland lagoons, and would not travel far afield to deface older formations in higher latitudes.

Moisture, as aqueous vapour, would only be found near areas of liquid—in any quantity, at least; but the great ice caps continually extending as the globe steadily cooled, would at last come more within the zone of solar influence, which would long retard glaciation on the equatorial seas (as internal heat had also retarded it in bays).

But, as secular cooling would still go on, the moisture raised off these seas, and diffused in the air, would pile for ages around and form the vast maritime ranges, the higher ridges of which, being cooler, would resist solar energy. Gravitation would transport an enormous amount of material literally *à la* glacier, and form vast raised regions, sloping gently from the main crest along the sea edge. The incline towards the warmer sea side would naturally be steepest, and at the actual sea level many thousands of feet below, in warmer strata, so to speak, by melting (at times of greatest solar influence), cause the precipitous profile there seen.

But at last even the seas would glaciate one after the other, by zones around the edges, leaving lagoons, large and small, here and there, as Archimedes, &c., and "clefts," due to subsidence, would appear as internal shrinkage went on. Where such "clefts," as huge crevasses, passed right down through the ice crust to the warmer and moister interior, they might give a series of orifices through which aqueous vapour would pass, and, congealing at the openings, form the strings of craterlets seen in many places, or may give but few openings, one here and there.

The existence of water (as liquid) at the surface, and the existence of air, seem to have ended simultaneously, and at last, after the period of piled cones and craterlets, any aqueous vapour given off flashed steam-like into the vacuum, and formed the well-known cloud, which, being of ice particles, would fall and form the equally well-known rayed white patch or nimbus around orifices.

I hope "F.R.A.S." will still look into the matter, and send any objections that he may see. I have no desire to bolster up a false theory, however ingenious it may appear. Also I hope Mr. T. Gwynn Elger may look into the above.

I would urge here that the question of complete absence of colour in lunar detail, even under the higher powers, be admitted as another argument, and added to those on page 127, April 10th. Surely if there has been water, we should see polar caps? Where temp. is admitted as low as 60° or 70°, and if polar caps are admitted, how comes it that there is no edge or line of demarcation from the tropics that are confessedly of same tint and structure? But, as far as possible, the various parts of this theory should be viewed together.

First, the probability that the temperature of the smaller globe is less than ours.

That there have been seas of water, and also polar ice caps, and that these *mares* are more like frozen sea surfaces, covered with bergs, than dried up sea *bottoms*.

That the entire series of circular forms from seas, like M. Crisium, to craters are due to formation of lagoons in a glaciating crust (the *floors* are all ominously level).

That this entire series beautifully illustrates decline of heat and atmosphere.

That the prevalent monotint is suggestive of an ice surface stained by meteoric dust that remains on the *levels*, and is removed by gravitation on the steepest inclines, as lips of craters and rugged mountains.

That the dark masses seen between Gambart and Copernicus are really *mountain peaks* that protrude through the ice sheet; also that volcanic surfacing, as a rule, is conspicuous for brilliant colouration on large areas.

That bays are *unfinished* craters, and not *deformed* circles, and afford proof of the truth of the lagoon origin.

That maritime zones are due to the seas solidifying first around the margins.

That "clefts" are huge crevasses, and due to subsidence of an adjoining area.

These are some of the main features to hold in view, as well as that Professor Langley's lecture at the Royal Institution bore out so completely the general *possibility* of this theory being sound.

**S. E. Peal.**

Sibsagar, Asam, July 26, 1885.

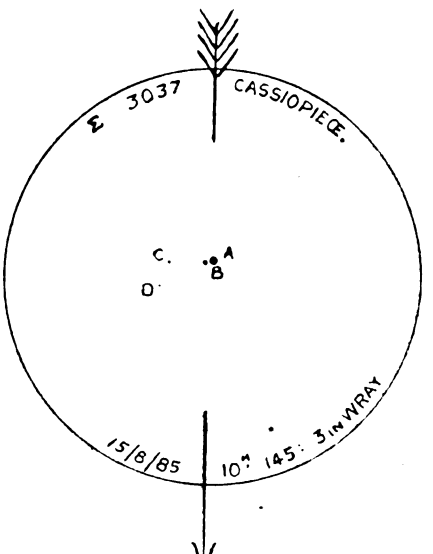
## Σ 3037 CASSIOPEIÆ.

[24670.]—Whilst observing this pretty triple on the night of Aug. 15th, I saw another *comes* in the neighbourhood of that given in "Celestial Objects" as of mag. 9.

The air was unsteady and the star very faint, so that I could but glimpse it now and then; but of its existence I have no doubt.

I should suppose it to be of about the 11th magnitude, the P.A. somewhere about 230°, and the distance from its primary from 40" to 60" ±.

The accompanying diagram may help to its identification; it is there marked D.



Would Mr. Sadler or Mr. Gore, to whom I return thanks for favours, kindly communicate the details of this fourth star?

Perhaps Σ 3037 Cass. may be classed among the quadruples.

Aug. 17. **H. D.**

## THE MICRO-OBJECTIVE.

[24671.]—The general method of mounting lenses is well known—I mean the burnishing them into a cell. It is also the best for a permanency.

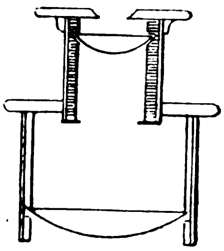
I will indicate two convenient methods which are easy to adopt for temporary work. One I use when mounting in triblet tubing alone; the other when I use additions to the triblet, or make special tubes.

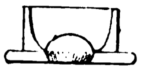
Suppose an eyepiece is to be made of two lenses having foci equal 1½in. and ½in. respectively. They are to be mounted just 1in. apart.

Cut (or make, if necessary) a piece of tubing which will just admit the larger lens, and in this case about ¾in. long. Cut another piece which will snugly slide into it, and let it be of the same length, but cut an eighth of an inch or more off the end. Thrust this narrow ring into one end of the larger tube; run a little solder in to secure it. The lens may now be put in its place, resting on the soldered ring, and when the inner tube is slid in it will be quite secure.

In the upper end of this inner tube a ring of brass may be soldered, carrying a smaller tube of ½in. length, carrying the eyelens at one end and the diaphragm at the other.

I will now suppose that the eyelens is to be mounted by the second method. Take a slip of stout zinc, of the right size to make a tube which will slide snugly into the small brass tube, if possible, but its inside diameter must be about $\frac{1}{20}$in. less than the lens' diameter. Before bending it into a tubular form, cut a channel along it near one edge, so that when it is bent the lens may be slipped into the channel, whilst the tube is sprung open, where it will be held securely when the tube is closed, and slipped into its place in the brass tube. These two methods apply only to lenses with thin edges. A modification of the first plan will do for thick lenses, such as achro-combinations.





In the trade they are usually worked to fit accurately-bored cells and cemented. I work them to fit, &c., but I usually leave a tiny collar at bottom of the cell on which the lens bears, and so it needs no cementing.

The small but thick fronts for an o.g. I mount with cement in a cell turned out of a solid piece, as indicated in the sketch accompanying this.

In the eyepiece sketch the light lines are brass, the dark ones zinc.
**Rob. Orus.**

## DAYLIGHT v. LAMPLIGHT FOR MICROSCOPIC OBSERVATION.

[24672.]—MR. NELSON'S views hereon (letter 24626) are curiously opposed to those of Dr. Carpenter. I quote from "The Microscope," 5th edition, page 169:—"The young microscopist is earnestly recommended to make as much use of daylight as possible, not only because in a large number of cases the view of the object which it affords is more satisfactory than that which can be obtained by any kind of lamplight, but also because it is much less trying to the eyes. So great, indeed, is the difference between the two in this respect, that there are many who find themselves unable to carry on their observations for any length of time by lamplight, although they experience neither fatigue nor strain from many hours' continuous work by daylight." Who is right?
**W. A. Cooper.**

## THE FIFTH VOLUME OF "HOLTZAPFFEL"—A DUBIOUS WORD.

[24673.]—I HAVE just completed the reading of the fifth volume of Holtzapffel's great work, and consider it, in most respects, a *chef d'œuvre*.

I am glad to see that the author has allowed someone familiar with the English language to do his "punctuating" for him.

Nothing could be more absurd than the punctuation of Vol. IV., which, in many instances, obscures the text hopelessly. One paragraph I have read over some dozen times, and I am not yet sure if I know what the author intended to mean.

Vol. V., however, seems quite free from this *bizarre* defect, and no one can fail to admire the beautiful photographic illustrations, although they cause the book to cost us, in the United States, at least 12dols. (50s.), which is a good deal for a book of that size.

I should be glad if Mr. Holtzapffel would give some explanation of a word he uses, page 587, where he speaks of a colouring material, presumably one of the aniline group, as "Orine."

This I hever heard of before. Does he, par hazard, mean "Aurine," or what?
**"Roi ne Puis, Souza je Suis."**
Brooklyn, N.Y., Aug. 10.

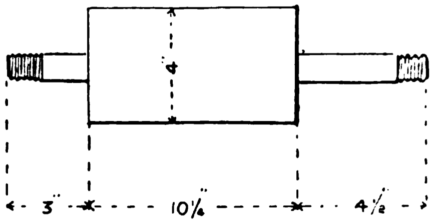
## THIRTY-LIGHT DYNAMO.

[24674.]—IN my last letter I described the construction and winding of the armature. After the armature is wound, and before the wires are soldered to the commutator, it must be thoroughly tested for insulation. The parts to be tested are the wire binding on the outside of armature for insulation from armature wires, the armature wires for insulation from the iron core, and the commutator bars for insulation from each other, and from the shaft and the washer that holds them together. The insulation of these bars being perfect, the armature, after being carefully examined to see that none of the wires bulge out, may be put on one side ready for mounting.

We must now turn to the consideration of the F.M.'s. The F.M.'s are really the most important part of the dynamo. The F.M.'s are to the armature what the boiler is to the engine. No matter what size the engine, if the boiler is not large enough very little power can be got out of it. In the same way, no matter how large the armature, if the field-magnets are not sufficiently powerful very little work can be got out of it; and to complete the analogy, the exciting coils bear to the magnets the same relation that the fire does to the boiler. From the foregoing remarks it will at once be seen, even by the most amateur electrician, that the field-magnets are the very life and soul of the machine.

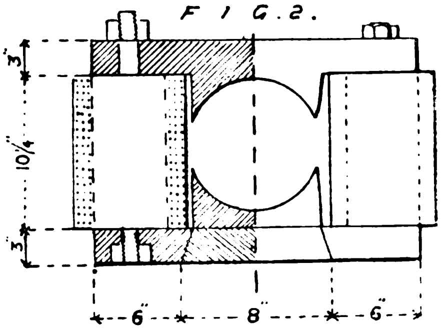
In choosing the type of F.M. to be used, I have had two considerations before me: a low resistance magnetic circuit, and simplicity of construction. During a practical experience of 5 years at dynamo construction, I have had many types of F.M.'s through my hands; but I think, on the whole, that the type adopted by Mather and Platt, Joel, Elwell, Parker, and others is the easiest, and, at the same time, one of the most efficient the amateur can construct.

FIG. 1



As will be seen by reference to sketches, the F.M. consists of two pole-pieces with extensions, and four upright electro-magnets. Fig. 1 represents one of these bars. Fig. 2 is a side elevation and half section. Fig. 3 is a plan of the bottom pole-piece, showing the position of the four magnet-bars. The sizes marked in the sketches are finished sizes, so the builder of machine must have the parts large enough to stand turning and planing. The pole-pieces are made of cast iron and afterwards annealed. I must warn the intending constructor to take his patterns to the foundry when they are casting machine work, as there is cast iron and cast iron, some specimens which I have seen resembling dirty sandstone more than anything else. When the bottom pole-piece is cast the lugs *c* and *c'* are removed, and the same pattern used for the top pole-piece. The electro-magnet (Fig. 1) must be made of the best wrought iron and carefully annealed. If it can be obtained, Swedish charcoal iron is the best brand to use, as it is so beautifully soft.

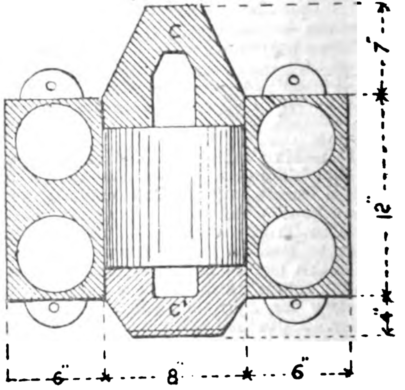
FIG. 2.



Having got our raw material, we may start on the construction of the F.M.'s. The first thing to be done is to have the upper surface of the bottom polar extensions and the lower surface of the top polar extensions carefully planed, care being taken to have a light finishing cut taken so as to bring the surfaces up smooth.

The next to claim our attention are the four electro-magnet bars. It will be at once seen that to insure perfect contact between the four bars and the polar extensions the bars must be of exactly equal length; the magnet-bars must also be of such a length that, when they and the pole-pieces are bolted together, the pole-pieces will be the right distance apart to give the armature its proper clearance. There are several ways of doing this; the one I have always used is to have a cylinder of wood turned right size—that is, the size of the armature and clearance. The bottom pole-piece is placed on the bench; the block of wood is then put in the position which will be occupied by armature, and the upper pole-piece placed on the top of it. The length of the electro-magnet bars can then be easily measured by observing the distance between the surfaces of the polar extensions. In the section half of Fig. 2 I have endeavoured to show the manner in which the cast-iron pole-pieces are bolted to the wrought-iron magnet-bars; the top pole-piece will be seen to be fastened by four ordinary nuts. But a somewhat different plan must be adopted with the bottom pole-piece, as the nuts must not project beyond the iron of pole-piece (the bottom pole-piece being used as a bedplate), and at the same time if recesses were cast in so that the spanner could be got to the nuts, the iron thus taken out of the body of pole-piece would considerably reduce its capacity as a conductor of lines of force, and this of course would lead to a reduction of the E.M.F. of the dynamo. If a hole were drilled and tapped in the polar extension, and the bar then screwed in, the difficulty would be overcome. At the same time, it must be remembered that if the hole is not drilled at a perfect right angle with the plane surface of the polar extension, the shoulder of the magnet-bar will not fit down snugly, and a great loss of magnetism would be the result. To overcome this difficulty, I have four square recesses cast in the under service of pole-piece, and in these square cavities I fit, somewhat loosely, a square nut. This nut is held in place while the bar is screwed down. The nut may then be loosed, and the screwing down of the bar finished by means of a pair of large pipe tongs. As the nut cannot turn round, the shoulder of the bar is drawn to the planed surface, and perfect contact made, even if the holes in the pole-piece are not quite straight. There are several points which I should like to go into, such as construction of brushes, holders, bearings, &c.; but as most of those interested in this letter will be quite capable of dealing with the questions, I think it would be occupying an undue amount of space to describe them in detail. I may say, however, that the bearings need not of necessity be adjustable. They should be made to carry a gunmetal bush, which being made to gauge, could be renewed in a few minutes. On no account use white metal or any other anti-friction metal which has a low melting point. I had a dynamo to repair some months ago which met with an accident from this cause. The machine was used for electroplating. The plater left the machine running while he went to his dinner, when, from the needle of the lubricator sticking, or some other cause, the bearing at the pulley end of the dynamo became so hot that the lining of the bearing melted, with the consequence that the armature wires were torn off. The brush holder should, of course, be made adjustable round the axis of commutation, and should be so arranged that it could be readily clamped in any position. The brushes, which may be either layers of copper strips or hard-drawn wires, should press on the commutator with just sufficient force to take up the current. Any pressure in excess of this only serves to increase the wear and tear of the commutator. In a well-made modern dynamo the spring of the brushes themselves is not relied on, but the pressure is obtained by means of iron or brass spiral springs. The amount of pressure exerted is easily regulated by turning the spindle on which the brushholder is supported. If the commutator does not run perfectly true, the pressure necessary to insure perfect contact will be com-

FIG. 3.



siderably increased. Grooving of the commutator, once the bugbear of dynamo manufacturers, is now almost entirely prevented by allowing the armature from ⅛in. to ¼in. endshake. The armature, moving gently backward and forwards while running, entirely prevents the formation of those rings which used to be so fatal to the life of the commutator and the temper of the electrician in charge.

We now come to the question of winding, and the proposition presents itself, Shall the machine be wound as a compound series or shunt? It is impossible for me to know the requirements of all those who may build this dynamo; so I think it will be best to give the sizes and quantity of wire required for each system, and then leave to the choice of the maker which system he pleases. Before I do this, however, I shall go into the different systems, and try to explain their respective advantages and disadvantages. We will take the series system first.

In a series dynamo the whole of the current generated in the armature passes round the coils of the field-magnets, with the consequence that on open circuit the E.M.F. at the terminals of machine is very small, due, in fact, to the residual magnetism of F.M.'s; thus, when a set of partly-discharged accumulators are introduced into the circuit the machine is instantly reversed. The series machine is at a disadvantage in lighting incandescent lamps, as, although this machine (series wound) would light forty 20's easily enough, yet it would not even redden two. With five lamps in circuit, the current passing round the F.M.'s being only about five ampères, the E.M.F. of machine would not rise to above 28 or 30 volts. The advantages of the series machine lie in arc-lighting, as its current can be kept nearly constant, while the E.M.F. varies within considerable limits.

In the shunt dynamo, only a part of the current passes through the coils of the field-magnets, the remainder going to feed the outside circuit. Unlike the series machine, the E.M.F. of the shunt dynamo is greatest on open circuit, and a single incandescent lamp placed between its terminals would be driven much beyond its proper candle power; as the current in the outside circuit is increased the current in the shunt-coils is diminished, and the E.M.F. of machine gradually falls until, with the full number of lamps in circuit, the E.M.F. of machine will have reached its normal amount, the difference in the amount of the E.M.F. between one lamp in circuit and forty lamps being about 12 volts. The shunt-machine has one advantage—it cannot easily be hurt by an accidental short circuit, and the disadvantage of the E.M.F. falling as the current is increased can be avoided by using a variable resistance. This resistance prevents the E.M.F. from rising too high when there is only one or two lamps in circuit. As more lamps are turned on, the resistance in circuit with the shunt coils may be decreased, and the E.M.F. kept constant; but as this requires someone to switch on more or less resistance as the lamps are turned on or off, it is rather inconvenient.

The compound winding has been introduced to obviate the difficulties experienced when shunt or series-wound machines are used. In the series dynamo the E.M.F. increases with the current; in the shunt dynamo the E.M.F. decreases with the current. It is thus possible to wind a dynamo with a certain proportion of both shunt and series coils, that their opposite effects on the steadiness of the E.M.F. may so neutralise each other that a machine with a constant E.M.F. will be the result. It as well, however, to observe that this perfect condition is seldom, if ever, obtained.

We must now consider the amount of wire required for F.M.'s, and I will take the series first. 100lb. of No. 10, 25lb. on each bar, all four bars connected in parallel arc, resistance of the four coils in parallel arc 0·6 ohm.

For plain shunt-winding, 90lb. of No. 16, 22½lb. on each bar, all four bars connected in series.

For compound winding 60lb. of No. 18, 15lb. on each bar, all four bars connected in series, and connected as a shunt on armature, 36lb. of No. 12, 9lb. on each bar, all four bars coupled in parallel arc, and then connected in series with armature.

It will be found best to wind the wire on a wooden framer of such a size that when the core was knocked out the coil would slip easily over the magnet-bar. This is the method of winding adopted on most modern dynamos, as in case of a breakdown of the insulation the coil can be easily removed for examination. In the compound winding it does not much matter whether the shunt wire is wound on first, and the series wire then wound over it, or whether the series and shunt wires are wound as two separate coils; so the builder of the dynamo may use that method which is most convenient.

The speed of the dynamo will be about 1,500 revolutions per minute, and at that speed the E.M.F. will be 48 volts at its terminals; this amount of E.M.F. is just right for Woodhouse and Rawson's 45 volt lamps, allowing for some loss in the leads. If it is desired to run 50 volt lamps, from 100 to 150 more revolutions per minute will give the extra E.M.F. required.

The amount of current which may be taken from dynamos with only one layer of wire on the armature is very large in proportion to the size of wire used. For continuous work (day and night) the density of current in the armature wires should not exceed 3,000 ampères per square inch, and for runs of from three to five hours' duration the density per square inch should not exceed 5,000 ampères. From these facts we may calculate the current the machine will safely give thus:

$$·109^2 \times ·785 = ·0093.$$

$$\frac{3000}{·0093} \times 2 = 64\ 4 \text{ ampères.}$$

It will thus be seen that when well made the machine will light from 30 to 60 20 c.p. lamps easily, and even if through bad workmanship the E.M.F. should be considerably reduced, the dynamo would still light what I have stated—viz., 30 20 c.p. lamps.

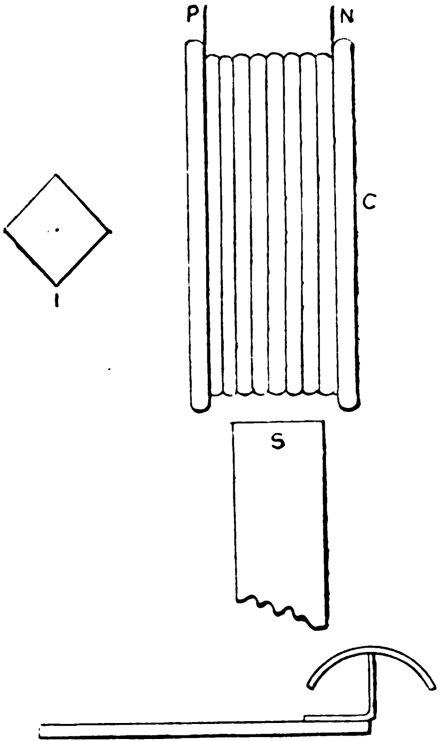
Spon-street, Coventry. **W. H. Eaves.**

---

## INDUCTION COIL ROTATIONS.

[24675.]—Inclosed is the illustration of an experiment I have recently made on rotary motion by vibration. The apparatus is a modified form of Lontin and Fonvielle's rotating disc, and can easily be made by any of your readers who are interested in the theory of electricity.

In the illustration C is a coil of silk-covered wire, No. 28, and about 30 yards long, something like a galvanometer coil, and is wound on a square frame made from a match-box; the opening is 1¼in. by ¾in.



A, B is a piece of sheet brass 4in. long by ⅜in. wide, having a common brass pin soldered at the end and fixed at right angles to A B; on this pin is set a piece of square sheet iron or tin ¾in. by ½in., with a centre mark made by a punch, and then bent, as shown, so that it may balance and revolve on the point of the pin, like a compass needle. The brass plate is fixed on a piece of wood (which is not shown), so that the square piece of iron can revolve either inside or just outside the coil C, as in the figure at I.

When the pole of a bar magnet S is placed, as shown, near the coil of wire, and the ends P N are connected to the pillars of the contact breaker of a common induction coil which has an iron core about 8in. by ⅞in., and 16 yards of No. 16 cotton-covered wire (no secondary coil is required), the square of iron I revolves very rapidly, as long as the battery current continues from one-cell Bunsen battery. Any piece of iron, such as a nail or screw, will revolve when suspended by a fine silk line; but if the piece of iron is long, there are four dead points in the rotation which prevent it revolving, unless it is first started by mechanical means."

The effect is owing to the action of the extra current on breaking contact; the rotations can also be produced by a battery of high electro-motive force, and a mechanical contact-breaker.

**J. Sutcliffe.**

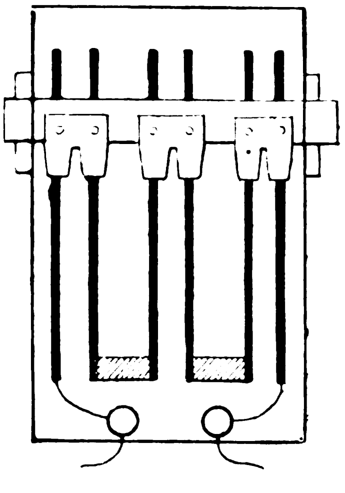
---

## VARIABLE RESISTANCE FOR USE WITH AMMETER, &c.

[24676.]—I inquired some weeks ago for a rough, quickly variable resistance for letting on a current quickly to an ammeter or galvanometer, so as to avoid the sudden swing of the needle.

I have found that Jablochkoff candles answer very fairly for the purpose used as a Poggendorf's rheostat; the conducting patch at the top being removed, and a slider fitted so as to bring any desired length of the carbon rods into circuit. The resistance of a candle 25cm. long is about 2·5 ohms, and several of these may be fitted into grooves cut in a piece of board and bedded firmly in cement, so that one side of the carbon rods projects slightly above the board. One rod of each candle is connected with the next by a strip of copper, and a slider with brass contact-springs is fitted on the board, so that the current may have to pass up and down along the whole series of rods, or any desired length of them.

An extra copper spring contact-piece (not shown in the drawing) is fitted to the slider, so that when pushed down close to the terminal binding screws contact may be made direct between them, and the resistance reduced to nothing.



If greater resistance is required, the rods, when firmly bedded in cement, may be scraped or filed down to half their thickness or less.

I do not recommend this as an accurate resistance measurer, but only as far preferable to any arrangement of wires for the purposes above indicated, or for rough-and-ready adjustable shunts.

**E. R. P.**

---

## WHAT IS "CREATION"?—ANOTHER ASPECT.

[24677.]—As a simple man, it has struck me as something wonderful that natural historians have always attributed Creation to external causes alone, without any reference to an internal power. I suppose that the peculiar education of the time being has prevented the mind from perceiving only half the tale. Evolution, sexual selection, hereditary features, adaptation and survival of the fittest, are only part and parcel of one general and particular law—viz., from a centre. Yes, you say, the universe is derived from the sun as a centre; but this is not so, for there are other suns than ours. Then there must be a universal centre, not only in one particular but in all, even the most minute. Can you find anything that does not proceed from a centre? Take music, a range of sound—say a piano. Now this is derived as to its visible substance from the universe, yet without the centre of sound it has no meaning or being. Strike the soundboard, or make all the strings vibrate at once, and there is only a void; but divide this vibration and find a centre, a middle C or A, tune each part in accordance, and a musical creation ensues. This central power exists in harmonic shape or mode from the bass to the treble, and is independent; but mark how it acts, never equally, but always in opposition to itself. Take a tensioned string. Its sound begins in the centre; if you strike or bow it here discord results, and there will be no creation; but analyse the sound into harmonics and the two halves act in opposition, and the divisions are unequal to the whole string.

Berkeley's philosophy intimates that things only exist because we perceive them; more modern thought insists that things or matter is the cause of perception. Goethe is bolder; he says—"Matter can never exist and be active without mind, nor can mind exist without matter." But there are vibrations both of string and pipe that are so quick that it is impossible to hear them, and also so slow that the sound passes away unperceived by the mind. It always ceases in the centre, whether quick or slow, because the centre of sound is universal.

Please allow another simile. Greenwich is taken or derived from the universe, and by itself has no relation to time, but being made a centre it is a creation, a measurement of distance and time. This creation is quite independent of Greenwich, for New York or Calcutta would do as well, yet it would be the same centre with different and opposing action as it is now. We are too apt to think that the universe is only that part that we see, whereas the greater part is unperceived. How about the impenetrable darkness that still covers the interstellar deep that is greater than our minds can perceive. Byron took one of his characters to the confines of the universe before it became a supposed darkness. But we know that the zenith becomes gloomy on the ascent of high mountains, and higher still would become a chaotic night. Is it true that one can see the stars in daytime by descending a deep coal-mine, or that the stars are reflected on the water down a deep well, and is the darkness always surrounding us? We can only have an idea of the universe from the particular centre that is our individual creation, and that idea only by contrast. There is no contrast without a centre to mark the difference, no balance, no lever, and no motion without this universal independent centre. A wheel can only turn round on an immovable centre, which centre is really the ground it runs on, say the fulcrum. Gravitation, attraction, action, and reaction are all governed by the same internal law, that always acts in opposition to itself, and which can never be understood by only observing one side of the question of creation by collecting external facts without considering the internal cause. This will be found in each individual creation. We only feel the heat of the sun, because we have an internal fixed temperature of our own, without which we should be insensible to heat or cold. Instead of saying that man is descended from apes, &c., it should be that all things are from one universal centre, which always creates with a likeness to itself, yet each individual is different to its own self and all others. I wish I could express my meaning better. **Fiddler.**

## WHAT IS CREATION?

[24678.]—WHILE I consider that this subject has now been pretty well ventilated in your columns, I may, perhaps, be permitted to reply to "F. W. H.," who was one of the original correspondents on the subject. He asserts (in letter 24662, page 546) that "Darwin's theories, showing evolution, adaptation, natural and sexual selection, &c., all working together *to bring about changes* in existing matter, are met by his opponents simply with crude assertions, &c."

Now, although I am not an opponent, even a humble one, I would advise "F. W. H." to read more carefully Darwin's voluminous and most interesting works, and I think he will see that he misunderstands the position taken by that great naturalist. Instead of bringing about new and original changes in organic forms, the phenomena which Darwin has embodied as a theory simply explain intelligently how, when new forms have appeared, they may be propagated—how a variety, appearing at first as a single abnormal specimen, may, in time, become a dominant one. He postulates over and over again in his works that, "*unless new variations do appear, natural selection can do nothing.*"

Now, the question under discussion in your columns has been, How do such new variations at first appear? I have unhesitatingly ascribed the phenomenon to "Creation," and have challenged "F. W. H." and others to suggest any other possible explanation.

"F. W. H." erroneously includes *evolution* with natural and sexual selection, adaptation, &c., as among the methods employed by Darwin in explaining organic nature, for, though I have carefully studied the whole of Darwin's works, I have not met with one instance in which he ascribes any phenomenen to "evolution."

In fact, "evolution," if it be not what I defined it in letter 24256, page 257, or if it be not synonymous with natural selection, must either mean spontaneous generation or an undefinable nothing.

If the term "creation" be obnoxious, I have no objection to substitute for it the term "transformation," suggested by "F. W. H.," subject, however, to my explanation in letter 24329, page 304, since no new transformation can be self-introduced or self-transformed; but as the more direct and lucid of the two I prefer the term "Creation."

**H. B. F.**

## SAFETY BICYCLES.

[24679.]—IF you can grant me the space, I should like to say a few words on the subject of safety bicycles, which I see has been lately ventilated in your columns. I cannot claim a long or varied experience, as, with the exception of the "boneshaker" of my youth, I had not ridden a bicycle until April, 1884, when I bought a Facile. I have since ridden some 5,000 miles, and I have no hesitation in saying that as a roadster the Facile is far superior to the ordinary bicycle: it is safe and comfortable, easy to mount and dismount, and certainly very fast. I am not by any means an athlete, being engaged in a sedentary business, and am 35 years of age. I am very fond of trying conclusions with anything and everything I meet on the roads, and yet I very rarely find a rider of an ordinary bicycle who is my equal in point of speed, be the roads what they may. I know several men who have given up the ordinary for a Facile, and they all say that they feel much less strain and fatigue after riding 50 or 100 miles now than they did formerly. I myself recently rode 155 miles in 20½ hours over some of the worst roads in Lincolnshire, and crossing the London stones from Highgate Archway to Peckham Rye, and suffered much more from want of sleep than from fatigue.

With regard to the geared Safeties, they are very extensively advertised; but I seldom see them about, although I frequent those roads where cyclists most do congregate. I see at least 20 Faciles for one other Safety. I have only been passed once by a geared Safety, and then by a man who is now one of the best Facile riders I know. From what I hear from riding men, I should be very sorry to exchange my Facile for any other Safety machine now on the roads. I will only add in conclusion that the Facile wants learning; no one can bring out its speed until some time has been spent in getting the feet and ankles used to the rapid motion of the pedals; but I am sure that those who give that time will find themselves well repaid.

Cyclists' Touring Club. **W. D.**

## MIDLAND ENGINES.

[24680.]—I REGRET to say that there is an error in my last letter (24639), which I suppose was caused by my general heading, "Midland Engines." I used it in an open sense—not limited, as would appear, to the large cylinder express engines. The two breakdowns mentioned occurred with the smoke consuming four-coupled engines used on the Metropolitan extension of the M.R.

The large cylinder type are, in my opinion, by far the best on the line, but I do not consider that their performances come up to many others. The Midland Railway Company are generally considered to own the best in the world; at least, their partisans say so. However, I am very glad to see by the letters in the "E. M." that there are some champions of the L. and N.W. compounds. I prefer the 8ft. G.N. engines for passenger express traffic to any others which I have tried, the run from King's Cross to Grantham especially, which is undoubtedly the best in England, being invariably taken by these engines. **Shylock.**

## L. & N. W. COMPOUNDS.

[24681.]—IN letter 24580 I stated my belief that, taken as a whole, the compounds consumed as much as the Precedents, if not slightly more. Nevertheless, I am greatly surprised at the figures given by "Kappa" (24641), showing, as they do, an average consumption by the two compounds of some 4½lb. per mile more than the six Precedents. This is indeed startling, especially as economy in fuel is the very *raison d'être* of all compound engines. I think the best compound in point of fuel is "Experiment," which burns about 28lb. per mile. The big compounds burn about 32lb., which certainly seems very poor as compared with the non-compound engines of the G. N. and Midland burning 26lb. In what respect does "Adiabatic" (24642) consider the compounds "wonderful"? In the coal consumption? Will "Adiabatic" tell us in what single detail the compounds are better than the Precedents? I totally fail to see their advantages, though their defects are obvious to all who are not absolutely blind. **G. D. Seaton.**

Aug. 24.

## THE SWADLINCOTE ACCIDENT: THE TWO-MINUTE BRAKE AGAIN.

[24682.]—MAJOR MARINDIN'S report upon an accident which occurred at Swadlincote (near Burton) on the Midland Railway has now been published, and attention is once more directed to the dangerous and inefficient character of the Clayton so-called automatic vacuum, or better known as the "two-minute" brake. On the 13th June a return excursion train, consisting of engine and tender, No. 1,440, and equal to 16 coaches, arrived at Swadlincote. The engine and tender had steam brakes and vacuum apparatus, the vehicles were fitted and worked with the vacuum brake. The engine was detached to run round the train, the vacuum brake was applied but leaked off, and the train commenced to run back. The line being on a heavy falling gradient, a pair of runaway or catch points had fortunately been provided, or doubtless the carriages would have run back two miles to the Swadlincote Junction with the main line, and come into serious collision; as it was the rear part of the train was thrown off the line at the points, and came into collision with three goods waggons; there were about thirty passengers in the runaway train, but they happened not to be in the vehicles which left the line. The facts of the case show at a glance the danger of the leak-off brake, and Major Marindin reports as follows:—

"It must be remarked that when the engine was uncoupled the continuous brakes were fully applied throughout the train, but the whole of them must have leaked off in less than two minutes. I cannot," he continues, "consider a continuous brake which leaks off in two minutes to be at all a satisfactory one, for it must frequently happen, as in this case, that it is desirable to hold a train by means of a continuous brake after the engine has been uncoupled, and in the case of a break away, either on an incline when running, or owing to a collision or other accident to the train, I can easily imagine that serious consequences might follow the release of the brakes so soon after their application. This slight accident should, in my opinion, be a warning against reliance being placed upon this brake under all eventualities."

A reference to back numbers of the ENGLISH MECHANIC will show that the dangerous "two-minute brake" has by its failures and inefficiency given the Midland Company numerous unmistakable warnings; it is to be hoped the leak-off system will be abolished before some really serious disaster occurs, as it certainly will sooner or later, if this unreliable appliance is continued in use. When the brakes return is published it will be interesting to see if this accident at Swadlincote is recorded in the list of failures.

**Clement E. Stretton, C.E.,**
Hon. Mem. A.S.R.S.

40, Saxe Coburg-street, Leicester.

## THE BINEGAR COLLISION.

[24683.]—As an old, practical signalman I should like to say a word. It seems it was a new line, and Colonel Rich had been down and inspected the arrangements. Well, he hadn't found them right and safe for traffic, and would have them altered. Mind, I speak as a practical man feels on the matter. When the Colonel found things weren't right, would it not have been better for him to have said, "This locking is wrong, I can't let you open the line till all is made safe"? Instead of that he seems to have said things are wrong, but you may open the line and put the locking right after. Can you or your readers explain why they didn't carry out the rules, and why was there no man at points as per rule 149*a*? **Signalman.**

## RIFLE SHOOTING.

[24684.]—ALTHOUGH perhaps not quite agreeing with "Invicta's" idea of the advantages to be derived from the use of Morris's or other tubes as a substitute for actual long-range practice, I certainly fail to see that his advice is as bad as "Bacchus," in his letter of last week, would have us believe. The reasons why these tubes are not of much utility as practice for long-range firing were sufficiently set forth in Sergt. Grey's letter of last week. Now as to the advantages of these tubes—and it is evident that they do possess some merit, as they would not have been admitted into the army, and have received such commendation from those who "ought to know." If "Bacchus" is a rifle shot, he cannot deny that plenty of aiming drill is an immense assistance to the eye, especially at a Wimbledon "bull" at 200 yards; and granting that he agrees in this, he cannot but agree that a mark, the size of a shilling, twenty yards distant is equally good practice, educating, as it undoubtedly does, the brain and hand to work in unison. Now it certainly is anything but interesting to stand or kneel for one or two hours before a mark and merely aiming and pressing the trigger, and obviously it is here that these tubes come in, and give pleasure and excitement to what otherwise would be but very monotonous work. We all like to see something for our trouble. Even the pea-shooting boy would be ill-content to blow wind, no matter how much he might be assured that his aim was straight; he delights to see the pea hit something, even though it be the tip of the nose of an unoffending nervous passer-by.

One word more. If recruits were trained more with Morris's tubes we should have fewer bullets whizzing about in all directions than we have now. Besides being less expensive, it would most certainly be more safe.

If "Invicta" would like good practice with the Martini at 100 yards—this should suit "Bacchus," as it is not converting the weapon into a small bore—here it is:—

Get a mechanic to bore a piece of steel to take a ·450 revolver cartridge easily, and let this steel be turned up to nicely fit into the breech as far as the shoulder where the rifling commences, and to have a rim the same size as that in a ball cartridge so as to fit the extractor, and this is all that is required to convert the military weapon into an excellent sporting rifle, and with it one may have good target practice with little noise.

Leicestershire Regiment. **J. S. Rochard.**

### VENTILATION OF COAL-MINES.

[24685.]—In reply to "Lyons," letter 24664, in your paper of 21st inst., "heavy" ventilation, as the present system is called, is stated to be the cause of more frequent and worse explosions than formerly. The reason is obvious.

When gas is about, a mine is really ventilated by a current of fire-damp travelling at a velocity that may fire a safety-lamp in less than a minute; especially may this be so in return airways. Now, the speed is here the greatest offender, since no lamp will fire in a low-speed current; besides, when gas appears, it has become a common practice to increase the velocity of the current, and so increase the danger.

Under such circumstances, what is best to be done? As it is at present, pure air in the down-cast shaft is sucked half-way through the mine, and in its advance so far gets fouled, and on its return gets worse fouled. Hence many a mine has been fired in the return airway by lamps or the furnace.

My argument is that one-half the quantity of foul air now passing the face of the coal would, if delivered there as fresh air, do far superior service.

The colliers would breathe a better atmosphere, while the speed of ventilation would be too slow for danger.

It should never be forgotten that a current moving only 7ft. a second—i.e., about good walking speed—is very risky.

In my opinion, the speed to the up-cast shaft or shafts of air delivered near the face of the coal, as I have suggested, would not exceed 4ft. a second. Thus that fruitful cause of explosions, "speed of a fire-damp current," would not occur.

Now, as to cost of engines, compressors, pipes, &c., no doubt it would not be done for nothing; but 6d. per ton would cover interest on the capital required. As about 500 men lose their lives annually by explosions in collieries, the question arises as to checking that loss at the price of 6d. a ton to the consumer.

I greatly prefer a moderate but sufficient supply of fresh air at a low velocity—which can do no harm, while doing much good—to huge volumes of foul air at a higher velocity, which is often most mischievous, and will continue to be so under the present system of "heavy ventilation."

August 24th. **J. D. Shakespear.**

### COLLIERY EXPLOSIONS.

[24686.]—It affords me much pleasure to discuss a question in the English Mechanic, provided the views I have expressed are correctly given when they are referred to by correspondents.

In your paper of 14th inst. is a letter (24606) signed G. Worlands, saying that "As a mining engineer, it will not be difficult for me to show that Colonel Shakespear's suggestions are practically of little value for the purposes intended."

Now I have not the slightest objection to that opinion so far; but when he makes out that I advocate that gas should be "kept back by a great pressure," he shows clearly that he does not understand me, nor the question of positive *v.* negative ventilation. I have never made, nor am at all likely to make, any recommendation so impossible to carry out as that of ventilating at a greater than atmospheric pressure. But that is very different from the practice of sucking the ventilating current from the down-cast through the mine to the up-cast shafts, for the tendency then is to lessen pressure; besides, the current is fouled both going and returning.

My argument is that air might be delivered under pressure near the face of the coal, which, on expanding as it would when free, resume ordinary atmospheric pressure, and become the ventilating current. Mr. Worlands has perverted that reasoning into an idea for heading back gas at a pressure of 30 atmospheres. The idea is nonsense, and not mine.

Mr. Worlands' remarks as to the value of discipline are right, no doubt; but explosions continue in spite of discipline, and will continue in spite of it, for the mine-storm below ground corresponds to the hurricane above.

Inst. C.E., Aug. 18. **J. D. Shakespear.**

### ALUMINIUM.

[24687.]—Many thanks for Mr. Allen's kind offer (letter 24600, p. 519). I will explain my present position. It is near 60 years since I became an experimentalist. My first patent for aluminium was dated Dec. 16th, 1856, No. 2,980. I commenced with calcining ammonia alum and obtained 2cwt. or 3cwt. of $Al_2O_3$. It was not remunerative. I then substituted cryolite, a double fluoride of aluminium and sodium only to be found, I believe, in Greenland. It was an improvement, but did not pay. The following is an extract from the *Chemical News*, May 26th, 1860, p. 291—the Society of Arts Exhibition of Inventions:—"In conclusion, we may briefly name the specimens of worked aluminium exhibited by Mr. F. W. Gerhard, the metal having been produced by the process of the above gentleman at his works at Battersea. We have never before seen the metal with so fine a tint and of such apparent purity." This was obtained from cryolite. Since that period I have been occasionally experimenting on a small scale in plumbago crucibles 2in. or 3in. in diameter, either in a Fletcher's gas furnace, or more frequently in a common fire-grate. It was in the latter that I made my successful experiment in obtaining Al and calcium without the aid of sodium about four years since. The problem was solved. I then commenced with the salts of Al, Mn, and Ca for electro-plating, and succeeded, the patents for which are now offered for sale (see the Sixpenny Sale Column). Should I dispose of them, I shall be enabled to have an appropriate place, which I have not at present, to make my experiments on a larger scale, and produce ounces and pounds instead of grains; but I find energy diminishes (age 75).

I had almost forgotten to name my last experiment. It was to produce crystals of alumina (corundum), and if I had added a few grains of the oxide of cobalt to the alumina, I should have had two or three crystals of sapphire. My process is superior to Ebelman's boracic acid process, which requires more days' heating than mine hours. Can you inform me of the properties of boron? I see it advertised at 2s. per grain. Suppose it could be obtained in large crystals, what would be their value? **F. W. Gerhard.**

Wednesfield-road, Wolverhampton.

### EXAMINATION OF MINERALS BEFORE THE BLOWPIPE.

[24688.]—No. 16. A double carbonate of barium and calcium, generally called "barytocalcite" (or "alstonite," from Alston Moor, in Cumberland, the only locality, I believe). This mineral is unique in its way. It is only found in one place in the world, and is, I think, the only mineral in the world which assumes a green tint by mere heating *per se*, as baryta and $MnO_2$ fuse together at high temperature, the mass assuming a green colour, Plattner was perhaps right in guessing the presence of a little heterodox manganese oxide in this mineral. On the other hand, neither Johnston, Delesse, Hauer, or Children, who analysed it, could find a trace of Mn; and I observe Col. Ross's system does not detect that oxide either. Professor Brush, in Dana's "System of Mineralogy," says, "with the fluxes, reacts for manganese"; but this is a mistake, as the merest trace of $MnO_2$ fused with soda, alongside the powder of this mineral fused with soda B.B. on Al plate assumes a brilliant greenish-blue like turquoise, whereas barytocalcite affords a dull, slate-blue bead, to my eyes, quite different. I inclose the two soda beads, and shall feel obliged if you will send them to Col. Ross for his inspection.

No. 17. Strontium sulphate, or "celestina." I maintain, with all due deference to Col. Ross's note, my opinion as to the similarity of the blowpipe reactions of this mineral and of "barite."

No. 18. Strontium carbonate, called "strontianite."

No. 19. Fluor spar evidently; but surely it affords more than "a *slight* choking smell" B.B. (due to disengaged hydrofluoric acid), considering it contains 48·7 per cent. of fluorine?

No. 20. Gypsum.

No. 21. Crystallised calcium phosphate, called "apatite" by Werner, from ἀπατέω—I deceive (probably from Spain).

I was not aware phosphoric acid, as well as sulphuric and carbonic acids, afforded effervescence in boron trioxide before the blowpipe. Col. Ross does not mention the reaction in any of his works on the blowpipe. **Mineralogist.**

### PYROLOGY.

[24689.]—As Mr. Allen is apparently tired of this subject, and must, besides, be very busy preparing for his Association visit to Aberdeen, I shall, with his acquiescence, drop it for the present; content with his admission that the ball of calcium pyroborate discovered by me is a new definite chemical compound (as, indeed, none but lunatics could deny), and that "no one doubts the fact that the ball is four times the weight of the lime used to make it, when small quantities are employed."

I have now in twelve years discovered about thirty other similar and equally obvious chemical compounds, which, although the combining proportions have not yet been determined, are entirely new to the science of chemistry. Besides these, there are some admittedly new substances, as, e.g., the black pyroxide of zinc, &c., and many new oxides developed by the use of aluminium plate as a support. Whether these are of sufficient interest to him and other leading English chemists to engage their leisure attention, it is for them to determine. They will not deny that a knowledge of them and their reactions upon each other anhydrously would extend and probably complete their knowledge of chemistry as a whole. Further than that, it seems to me, and even to some very eminent professors with whom I have conversed on the subject, that the English chemist who first could and would "seriously" take up the study of this subject, and patiently strive to assimilate the results he obtains with the known analogous reactions of the same substances in aqueous solution, would probably stand at the head of his profession.

For myself, I am too old to undergo the (to me) necessary course of study in aqueous-solution analysis; and, besides, the Government laboratories (which I consider I have contributed to keep up by my taxation all my life), where I should have to undertake such a course, are exceedingly expensive in the way of fees, &c., instead of being, as they ought to be, free to taxpaying students, who would, of course, pay for use of apparatus and reagents.

Again thanking Mr. Allen for the courtesy and and ability with which he has conducted this discussion, I beg to conclude it by stating in reply to his last query (page 519, "E.M.") that you cannot employ a platinum crucible in anhydrous analysis, (1) because platinum itself at *red* heat communicates opalescence to borontrioxide, just as calcium, hydrate does; (2) because you cannot maintain a sufficiently high temperature in the menstruum and its contents through the "walls" of a crucible; and (3) because the effects of oxidation and reduction cannot be thus properly applied to the assay for the same reason. In short, you must have *direct application* of the different parts of the pyrocone to the assay. **W. A. Ross.**

P.S.—I hope Mr. Allen does not really think I would "attempt to ridicule the wet methods." My object was to show that the blowpipe properly used is as close a detective of traces of oxides, &c., as even the spectroscope, especially when used in conjunction with the microscope.

### A NICOTINE SYNTAGMA.

[24690.]—Those of your readers who have done me the honour of using and approving of my condensing tobacco-pipe are aware that its greatest defect was the horrible smell of the nicotinic essential oils evolved by it when the protruded end of the sponge in the unscrewed mouthpiece of the new pattern was defecated in squeezing out the "juice" during a smoke by the pressure of the breath, blowing the sponge against some opposing surface.

In the open-air this was of no great consequence, as the smoker can generally find a wall, or post, or tree against which to press the sponge while he blew out the collected empyreumæ; but in a room the difficulty of doing this inoffensively constituted a very serious drawback to the enjoyment of my pipe in company.

I think I have now completely overcome this defect by a piece of smoking-room furniture, to which I have given the name of a Nicotine Digester or Syntagma, because it instantly absorbs the offensive products of smoking without communicating any smell to the room. This is effected by pressing the protruded sponge-end of the mouthpiece, strongly blown through, against the side of an ordinary yellow well-burned house-brick cut in half; this pressure leaves a small, dry, brown strain on the surface, but no smell, even on any other side of the brick itself. The half-brick is inclosed in an ornamental bronze filagree stand, having four open sides, and placed on the table on the left hand of the smoker. The stand has a door for admission and extraction of the brick, and a handle for the smoker to hold while he presses his sponge against the brick, the unscrewed bowl of the pipe being placed, *pro tem.*, on the table. After long use the brick is purified simply by being put into the kitchen or other fire for a short time.

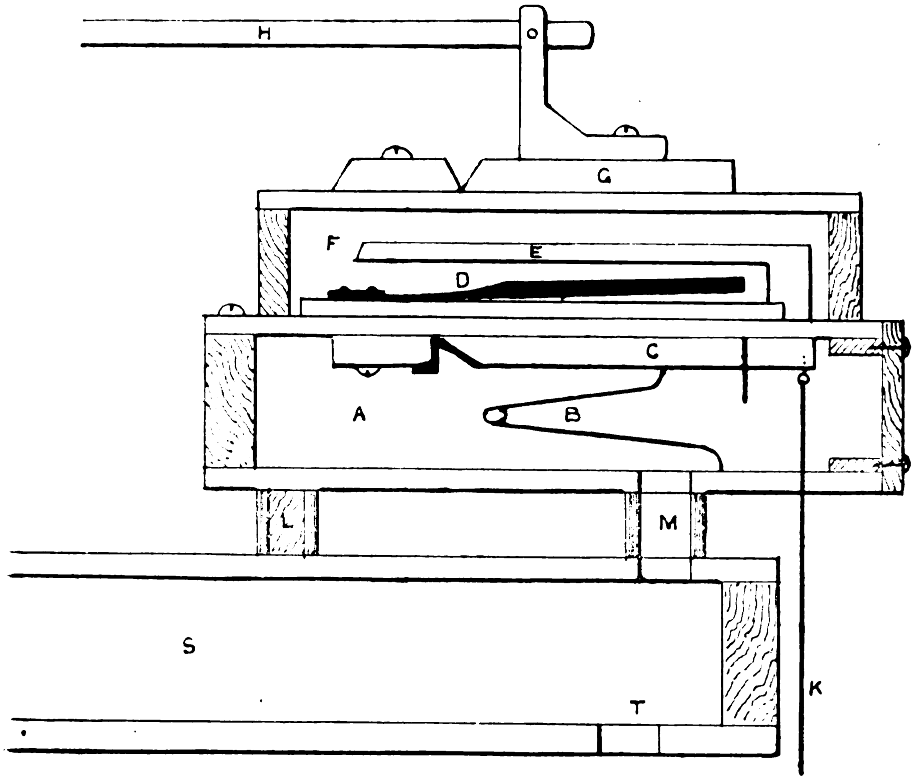
The principle is this. The alumina of the brick becomes semi-caustic by burning, and then possesses intensely absorbent qualities for fluids, evolving with water or saliva a well-known strong, but not unpleasant, odour, which overcomes that of the small portion of the nicotine unabsorbed by the brick.

N.B.—This implement could, of course, be easily fixed on the inner sides of smoking-carriages of railways; when there would be no more pools of the disgusting discoloured saliva usually found on the floor, as no one expectorates in using my pipe. A few drops of scent may now and then be put with the forefinger over the spots.

A friend suggests that slips of firebrick might be slid into the lids of the ordinary metal fusee or "light" boxes. **W. A. Ross.**

### AMERICAN ORGAN PEDAL BASS ATTACHMENT.

[24691.]—As proposed, and promised by me on p. 374, Vol. XL. of the English Mechanic, I send sketch and brief description of a good arrangement for an American organ pedal bass attachment. In sketch, A shows the windchamber, in which are situated the pallets in connection with the pedal bass reeds. The pallet springs are fixed similar to those found in small pipe organs. The pallets are actuated by pull-down wires connected to inner ends of pedals. The reeds and tubes are mounted on a sounding board, distinct from that of the instrument to which the arrangement is applied. In fact, Seen by me for the 1st time 30 Oct /85 [illegible]



the whole arrangement is entirely independent from the American organ action. The attachment should be raised from the soundboard of the instrument by two standards and also two tubes, the latter applied for the purpose of conducting the air to the pedal bass reeds, and also to partly act as a support for the arrangement. If the arrangement, or action, is raised about 1½in. above the soundboard of instrument, that will be sufficient. It is simply intended to be raised from the soundboard, in order to facilitate the operation of access to the back rows of reeds of instrument. If preferred, the pedal bass reeds and tubes may be mounted on the main soundboard of instrument, but in this case the pallet action would require to be arranged somewhat different to the method which I here describe. It may be necessary to remark that this pedal bass attachment is most suitable for those who contemplate building an American organ with a separate pedal bass action. It can also be applied to ready-made American organs, providing there is sufficient room at the back portion of the soundboard. As in pedal practice there are never more than two reeds sounding at the same time, the amount of air required is not very considerable; but the pressure of air certainly demands some consideration, as the pedal bass reeds will not speak well under a light pressure. In reference to sketch, B shows pallet spring, C the pallet, D the reed, E the tube, F the soundbox over tubes and reeds, similar to that usually placed over the horizontal sub-bass arrangement. G is the mute controlled by the stoprod H. K shows the pull-down wire connected at the upper end to pallet, and at the lower end to inward end of pedal. S is the windchamber of American organ to which the arrangement is applied, and T shows the windway to bellows. L shows one of the standards, and M one of the conducting tubes. On four of these (two at each end)—viz., two tubes and two standards, the whole of the pedal bass action rests. I think this may be considered one of the most simple, and, at the same time, one of the most effectual arrangements for a pedal bass action. If this method is employed, it will be difficult and inconvenient to adopt a compass over two octaves of pedals. The tubes and reeds of the pedal bass should be so arranged on the soundboard as to allow a space of 2½in., or a very trifle less, between each natural note, from centre to centre. There is another arrangement which I shall shortly describe, in which the reeds are placed in vertical tubes, like small organ pipes. The latter suggested plan is somewhat superior to that which I have described, but it requires a certain amount of room for the tubes, which is not to be found in American organs generally. The greatest desirability in arranging a pedal bass is to procure a good sonorous tone, full and round, a tone that can be felt as well as heard, and differing from the weak and dingy rattle so prominent in many of the sub-bass arrangements.

**G. Fryer.**

## WATCHMAKERS' QUERIES.

[24692.]—Referring to letter 24655, I think the reply by "Peganredstuff" is quite clear. The vibrations of the balance may easily be found by multiplying the numbers of the wheel-teeth from, and including, the centre-wheel by twice the number of the escape-wheel, and dividing by the product of the pinion leaves. Having found the required number of vibrations, say 18,000 per hour, which is equal to five per second, fix on the balance spring by pressing the collet down over it; take hold of it at a radius equal to the distance of the stud from the centre of the balance; now set vibrating, and count. Two or three springs may have to be tried before one is got to suit. With a little practice it is easy to count every second or double vibration so near that when pinned in the watch, in many cases, it is only a few minutes wrong in 24 hours.

"Escapement's" method may do when there is an old spring as guide, but is quite inapplicable when the spring is wanting altogether. If two balances of the same weight, but one much larger in diameter, be tried with the same spring, the large one will vibrate much slower owing to its radius of gyration being greater, although when weighted the spring will be deflected the same with both balances.

This method of fitting springs is only suitable for common watches, as when isochronism has to be taken into account the operation is rendered much more difficult.

22nd August. **G. W.**

## LATHE WORK AND OPTICAL INSTRUMENTS.

[24693.]—I was glad to see the letter of "An Amateur" (24650) in your last issue, and hope someone, able and willing to do so, will give your amateur readers, especially those living in the country who have no opportunity of seeing certain kinds of work done, some practical help on lens-grinding, and making the necessary tools for such work. The papers should be illustrated by good working diagrams.

**H. A.**

---

## THE SOARING BIRD—A MECHANICAL PROBLEM.

[24694.]—Having read with much interest the leading article in "Ours," of Aug. 14, upon this subject, I must say that I thoroughly object to Mr. Lancaster's theory; for the sufficient reason, in my opinion, that he assumes that the action of the air upon an inclined plane which is free to move would produce an upward current, but ignores the fact that an inclined plane to move in any direction would certainly travel backwards and downwards with a speed proportionate to that of the air which sustained it, and unless sustained by a power unknown to us, would not wait one instant for the commencement of said upward current. Now, I have also witnessed this soaring of sea birds in warm latitudes, and venture to submit two theories to the crucial criticism of the critics of "Ours." I start with the proposition, which I am prepared to prove if anyone disputes it, that everything upon this earth is unceasingly in motion, although it may be invisible to the unaided eyes of mankind. 2. There cannot be any kind of motion whatever without friction; and, 3. There cannot be any friction, of which I am aware, which does not develop electricity; but because almost, if not all, the bodies conceivable by us are conductors, more or less. This universal and ceaseless production of electricity has been heretofore suffered to go on without any apparently, to me, of our savants endeavouring to turn this feature of the electric problem to the advantage of mankind. Now, all electricians are aware that when two neighbouring bodies are charged with electricity of the same name —viz., + or −, positive or negative, that they will repel one another with a force proportionate to their mutual areas. Thus, this soaring taking place in warm air, I am, I think, in a position to prove that said birds can be and really are highly charged with electricity, and that also in a state of high tension. I consider this theory to be consistent with fact when we bear in mind that suitable apparatus will show that even the working of the brain acts as does our ordinary pumps in this respect, and collects this all-pervading electricity; but, apparently, according to my present light, only to be spilled, as it were, upon the ground again. How these facts have hitherto escaped the notice of electricians making this branch of science their assiduous study, I am at a loss to understand, but trust that I will be in a position shortly, when I have secured my rights by patents, to publish a new treatise upon this most interesting topic, accompanied with descriptions of entirely novel experiments and results, as will render a new text-book upon this subject far more important than the newly-revised Bible appears to be. This electrical theory as to bird soaring is the one that I prefer myself; but a prudent general always provides for a means of retreat, and I propose theory No. 2 as a base in case of a possible defeat upon No. 1. Most of "Ours," I conclude, then, have, at some time in their career, worked up a piece of fresh bread into a ball about the size of an ordinary pea, stick a pin through the same, and placing the pin in a suitable piece of pipe stopping; then throwing back the head (not of the pipe, but that of the operator), holding it vertically (the pipe stem). Upon blowing, the pin and pea dance about upon the ascending column of air for a considerable time before some inadvertent change in the conditions causes them to fall. Some also, as well as myself, have doubtless taken a piece of pipestem, made a hole in a piece of board, inserted said stem therein level with the board's upper surface, holding board horizontal, and placing over the orifice of said small tube, say, a watch-glass with the concave side downwards. No amount or pressure of blowing underneath can blow off the said watch-glass. A bird's wing is not, in my experience, a flat plane. It is decidedly curved on both sides—upper side convex, and the under one concave—which formation I have carefully studied, and offer the following explanation: In the case of the bread pea, I submit that when we blow, the pressure of the issuing column of air raises pea and pin, which would instantly fall off were it not that any column of water or air issuing from any given orifice draws a certain amount of the body surrounding it, if said body be capable of motion, along with it. Take the ordinary injector as a case in point, and in this case the air rushing in from all sides, save that where column of air occupies, keeps said pea in position. In the case of the watch-glass, we have a column of air of relatively small diameter impinging upon the centre of the curved surface, and turned off on every side at an angle. It rushes freely down the curve and produces a partial vacuum under the whole area of said glass, so that it is pressed down with considerable force instead of being blown away, as one might naturally expect to see; and lastly, in the case of the bird's wings, if there be any wind stirring it strikes the curved surface, and its horizontal motion is gently converted into a curved downward motion, which causes a rush of air off the upward surface of said wings, in obedience to the laws I have enunciated. Consequently, the bird's body endeavours, as it were, to occupy the partial vacuity, or rather, is pushed up by the underlying air. If the bird allows itself to fall when it is calm, precisely the same result will follow, only that the air will rush past the wings and take the air on top of same along with it, thus producing the same upward tendency of its body. In conclusion, permit me to submit these two theories to the readers of "Ours," as being more practical than the American one upon page 509. I submit that he is entirely in error as to the conduct of a flat surface or body set free in air.

**A., Liverpool.**

---

## AUTOMATIC MUSICAL INSTRUMENTS.

[24695.]—A correspondent having given the number, I have obtained Mr. Wenham's specification, which has cleared up certain points which I had not quite comprehended from his letters in the "E. M."

The arrangement is certainly a very clever one, and as simple as it is clever; but I would ask Mr. Wenham to kindly reply to a couple of questions relating to its actual working. Since the plungers are all in the same line, they must necessarily be placed about the centre of the white keys in order to (at the same time) act on the black keys; but in order to depress the black keys fully, it is necessary for the plungers to have a stroke of ¾in., while the extreme depression of the white keys at this point of their length is only ⅜in. Since the vibrating bar depresses all the plungers equally, it must happen that while the white keys are struck down to their full extent, the black keys are only struck down half-way, from which peculiarity one would expect considerable differences in the loudness of the notes and consequent irregularities in the music. The other question is this: When a note has to be rapidly repeated, is the plunger pushed under the vibrating bar *for each repetition*, or is it left under the bar till the number of repetitions is complete? In the former case it would apparently be necessary to insure very exact time between the passage of the paper strip, and the movement of the bar; while in the latter case the repetitions might be more rapid than the music required.

I am rather surprised that cartridge paper is found rigid enough to work the levers and bell cranks, and overcome the inertia of the long connecting wires, not to mention the resistance of the springs, that throw up the lever points into the perforations. Since I last wrote I have seen several more varieties of these instruments, but the only one that struck me as of special interest was an arrangement by which the "pneumatic action" long since used for large pipe organs was adapted to these little automatic concerns. By this method the perforations were able to be made much smaller, and more reeds acted on for a given width of paper band. I think about 9in. width of band controlled 30 or more reeds. If any correspondent can give me the particulars of the specification, I should like to get a copy, as though the principle is old the arrangement of the parts (so far as I could see them) was new, and was also particularly neat and compact.

I am glad Mr. G. Fryer is about to fulfil his promise to send a drawing of a complete instrument. If the reeds in his two-row arrangement are so placed that those opposite each other in the same channel are a note and its "twelfth," a certain amount of variety is obtainable by allowing one or the other or both simultaneously to sound by suitably-placed valves commanding the air passages. I use the expression "twelfth" as if it was an organ, as Mr. Fryer will readily understand.

A. S. L.

### AN EASILY MADE RAIN-GAUGE.

[24696.]—Yes, the gauge described in letter 24646 is very easily made, but very bad when it is done, for the rod rising above the funnel will collect rain which ought to pass over it, and will make the gauge show several inches per annum too much. Moreover, if frost catches any rain in the gauge a leak will soon follow. G.

## REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[56031.]—**Reservoirs (U.Q.)**—Thickness of a tube 12ft. long by 72in. diam., to collapse with a pressure of (14 × 3) = 42lb. will be ¼in. Ends dished inwards to a radius of 6ft. The above gives minimum thickness. I should make plates ⅜in., and put a few angle bar rings, say 3in. deep, round outside to preserve the circular form.—Glatton.

[56440.]—**Warnerising (U.Q.)**—The waterproofing liquid is prepared by dissolving 1oz. caoutchouc, or other elastic gum, and 1oz. paraffin or other wax in 1 gallon of any hydrocarbon solvent, such as benzoline. Hydrochloric acid gas or chlorine gas is passed through this solution for some time; it is then filtered or decanted, the clear liquid placed in a retort, and distilled at a temperature of 145-165° Fahr. When the vapour distilling over is no longer acid to litmus paper, the distillation is stopped, and nine-tenths of the liquid in the retort is drawn off. This portion is claimed to be perfectly free from acids or alkalies. Full particulars will be found in the patent No. 5,486, 1882, Nov. 18, price 2d.—Alto Petit.

[56961.]—**Boating.**—Many thanks to "Invicta" and others for their replies on this subject. I think it cannot fail to be of general interest to many of our readers. I earnestly join with T. Handel in hoping "Invicta" will favour us with particulars and sketch of the method he considers best; and that J. Adams will give us full details of the one he speaks of going eight miles an hour with half the labour of rowing. I think T. Handel's arrangement might be considerably improved upon. In giving details of propelling arrangement, kindly give dimensions of boat, and particulars and dimensions of paddles or screw. Is the paddle or screw the most economical, both as regards power or speed? Would the outside of the boat not be best covered with canvas? Could the most power be got from the hands or the feet? I hope this subject will not be allowed to drop until something definite and useful is brought out.—Aqua.

[56985.]—**Planing Machine.**—Press of business must be my excuse for not thanking "J. H." for his kind reply to my query before, and for sketch. Many years ago it came to my lot to fit up a machine from similar castings. In them the weakness feared of the V's breaking off was avoided by making the thickened portion containing the hollow V a little deeper, thus affording more support, the rack frame being made so as to match, and though only about 9in. longer, I never remember its lifting under cut. I advocate this form of V because, in the case I mention, it being well planed, the surfaces had only to be smoothed, and required no further fitting. Perhaps one reason of its steadiness was owing to the V's being barely half as wide as yours, and much more acute. I regret much forgetting the dimensions of this table, as I am anxious to know what should be the depth and weight of a carriage of the same area as yours to be exempt from lifting under cut with V's as I propose. From some crude experiments I am led to believe that it is quite possible to modify this tendency of rack and pinion to separate or the reverse, by timing them to each other so that the ascending teeth only shall engage with the rack in the first case and the descending in the other.—J. C. G.

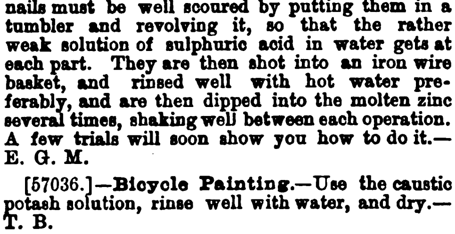
[57028.]—**Stamping in Relief.**—There are any quantity of receipts for lacquer in back numbers of the "E. M.," but the base of nearly all is shellac dissolved in methylated spirit. Writing from memory, I should say that about an ounce of shellac to one pint of the spirit would be amply sufficient, and if you would like a coloured lacquer a little of any aniline dye can be added. The lac will require a day or two to dissolve (giving it an occasional shake), and the insoluble portion will settle to the bottom of the bottle. The clear solution must now be poured into another bottle for use. Bottles should be clean and dry before use. The articles to be lacquered can be placed on an iron stove or on a sheet of iron over an ordinary fire till they are about as hot as can be held, and a thin coating of lacquer brushed on with a camel hair or other soft brush. If they are too hot the lacquer will blister and spoil the appearance at the right heat; the lacquer will dry smoothly the moment it is put on. The same part should not be brushed twice over. I have been told that the lacquer can be applied to the brass when cold, and then afterwards heated till the lacquer gets transparent; but I have not tried this method. A smaller and lighter press will do for stationery, and can be bought second-hand also for a very few shillings. It is far better and cheaper in the end to put every tool to its proper use; anything in the shape of a makeshift always causes a loss of time. Your own judgment will require to be used in these matters, and it will not take you long to experiment on a piece of paper with the dyes and press you use for the brass, and if they will not do you can then get something else that will.—Os.

[57030.] — **Galvanising Clout Nails.** — The nails must be well scoured by putting them in a tumbler and revolving it, so that the rather weak solution of sulphuric acid in water gets at each part. They are then shot into an iron wire basket, and rinsed well with hot water preferably, and are then dipped into the molten zinc several times, shaking well between each operation. A few trials will soon show you how to do it.—E. G. M.

[57036.]—**Bicycle Painting.**—Use the caustic potash solution, rinse well with water, and dry.—T. B.

[57065.]—**Cork-cutting Machine.**—Will not the illustrated description on p. 181, No. 970, do for this querist?—Nun. Dor.

[57116.]—**Bell Telephone Circuit.**—To Mr. Bottone.—Perhaps the following arrangement is the best under the conditions. T and T′ are the telephones (shown detached from the microphones for clearness' sake), M and M′ the microphones, S S′ are switches, on turning which the microphones can be thrown in or out of circuit, as also can the telephones. B is the battery, L the go, and R the return wire. T′ is shown as sending, T as receiving. The circuit is complete through R, M′, D′, L, T, S back to B. If the switch S be placed so as to make contact with M, while S′ is placed against X′, then T can transmit, whilst T′ can receive, since the circuit is now complete from B to S; from thence throw M to D, L, T′, S′, R, back to B. No coils could be used on this single battery and single line circuit.—S. Bottone.



[57122.] — **Problem.** — In the solution by "W. A. S." ought not the – 4, six lines up from the bottom to have been divided by 20 like all the rest of the equation? I admit my inability to work it out, or even to understand how "W. A. S." obtains his results, as I never learned the modern system of putting all the terms on the left hand side, and making them = 0, which, I suppose, simplifies matters to those who are used to it.—J. K. P.

[57166.]—**Model Well.**—Thanks to Mr. Scudamore; but he has, I think, failed to understand my query. Out from the side, and close to the bottom of a leaden cistern on end, a siphon is soldered; the cistern is supplied by a tap from another reservoir. My query was: "The bore of supply-pipe to the leaden cistern being smaller than pipe forming siphon, how is it able to fill the latter at the bend, drive out all air, and cause siphon's action to commence?"—H. A.

[57182.]—**Great Northern Locomotives.**—Errata.—A fortnight since I wrote that the trailing wheels were 3ft. 6in. It should have been 4ft. I mentioned also that I thought a new broad gauge was being built with 9ft. wheels; but I find on further inquiry it has only 8ft. drivers.—Angus MacMuir.

[57183.]—**Planing Machine.**—To F. Shakespear, Dresden.—The answer given to this query by "J. H.," on p. 527, is correct according to the way in which he understands the query itself. I interpret it differently, and should say that the way to make your "clamps" and angle-plates hold their work is to "cramp," not "clamp," them together by means of horizontal bolts. In this way a couple of angle-plates make a very excellent parallel, or even angular vice. A "clamp" is a structure of unburnt bricks arranged for burning, and a very unsavoury structure too. A "cramp" is a mechanical arrangement for bringing things into close contact, either by screws as usually done in mechanical arrangements, or as in masonry, by bending down the ends of a small bar of iron to form what are called by some "corkings," or, in my opinion, more correctly, "calkings"—i.e., *little heels*; and these cramps are fixed by pouring melted lead into the groove in which they lie. They first expand with the heat, and then contract and "cramp" the work forcibly together. A *clam* is another thing altogether, being merely a plain piece of wood, metal, cork, or any other substance introduced for preventing the work under treatment being injured by teeth or jaws of vice, chuck, or other "cramping" arrangement. Thus far I wrote for insertion in last week's issue, but forgot to forward it. Curiously enough, the job I now have in hand required holding in the manner above described, as it was too high to plane safely in the ordinary vice. I happened to have by me, ready planed up, two castings of angle-plates, 6in. long, the branches of the ∟ being 2⅜ and 1⅜ respectively, and ⅜ thick. One bolt to each held them down perfectly, and a pair of iron rods screwed on both ends for the nuts held them together effectually. This was without the use of any set screws. Of course, in this case, the work being only about 4in. wide, there was room to put the tie bolts *outside* the work, and as it was of the form of a capital ∩ (upside down), it would have allowed of one through the middle, and that would have sufficed, and in many cases the work may be raised and have the ties under it; but often it is necessary to select your angle-plates of some greater length than the work itself, and put the ties outside.—J. K. P.

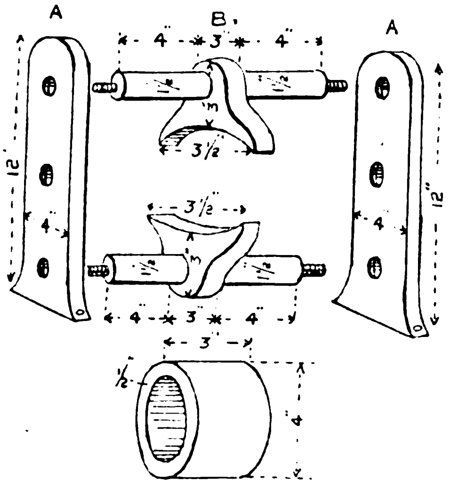
[57185.] — **Dynamo.** — To W. H. Eaves, Coventry.—When I read your query I expected you had made a mistake, and allowed for it; but as you have now given me the exact size I can advise you more correctly. Wind the armature with a single layer of No. 18 double s.c. wire, and for the field-magnets use about 30lb. of No. 18 d.c.c. wire. At a speed of 2,000 per minute, you will get from 50 to 55 volts, with a current of 12 ampères, including that required to excite the F.M.'s; so you may reckon on getting 10—20 c.p. lamps from your machine. Be sure you have a very powerful field, and use the best iron you can get in the armature rings and F.M.'s—W. H. Eaves, Coventry.

[57189.]—**Income-Tax.**—I have evidently made a mistake here; but although my general conclusions were not correct, the advice I gave was so.—Os.

[57201.]—**Violin Strings.**—It is difficult to give accurate dimensions for double bass strings, as they seldom run even all through their length, and also lose in diameter as they stretch and dry with use. I have just measured one of mine and find them $\frac{11}{100}$, $\frac{15}{100}$, $\frac{20}{100}$ of an inch, but believe that on another bass of mine, which I cannot refer to, as it is at the Loan Exhibition, the diameters would be found rather smaller. The third string appears rather thick in proportion; but this allows of your tuning down to G, which is now very usual. Of course Bottesini, for solo work, uses much thinner strings; but he usually tunes to a much higher pitch. A set of the best Italian strings should cost about 15s., but you may buy others much cheaper, although I think the economy doubtful.—J. W. M.

[57201.]—**Violin Strings.**—Take your instrument with you to any respectable music shop. You can there ascertain the "probable cost" and "relative thickness" of the double-bass strings. I quote prices of good strings, in case the querist should not be able to take the advice offered above. Firsts, superior, 3s. each, Roman, 5s.; seconds, 5s. and 7s.; thirds, 7s. and 11s. All double-basses are not made strictly to one measurement or form, and the quality of tone produced depends chiefly on the care bestowed in its manufacture, and also on the quality of the material used. The quality of the strings used is also of some importance with regard to the quality of tone. You will find a string gauge very useful when you want to purchase a set of strings. Always keep to one particular gauge for each string. This advice holds good both for violoncello and ordinary violins, as well as for double-basses. The distance from foot of bridge to soundpeg can be ascertained by measuring.—G. FRYER.

[57221.]—**Gramme Dynamo.**—To MR. BOTTONE.—The inclosed sketch shows the dimensions and form of the parts required. One pattern will serve for both the standards, A and A′; also the field-magnets, with their horns, B and B′, can be cast from the same mould. The armature can be cast; but would be better, if made from sheet iron, by rolling up. You will require about 6lb. of No. 16 on the fields, and 2lb. of No. 18 on the armature. The more sections you have in the armature, the steadier the machine will work.—S. BOTTONE.



[57223.]—**Chemical Action in Leclanche.**—I think it would have been better had Mr. Kean (p. 549) corrected the equation given. The reduction of alumina by sugar itself would be a mere detail compared to the spontaneous generation of manganese and oxygen in a Leclanché cell.—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[57224.] — **Prevention of Noise.**— "Spes" will find a cue to the solution of his difficulty about the transmission of sound by taking a wooden rod, say, 20ft. long, putting a watch at one end, and his ear at the other, when he will hear distinctly the ticking of the former. Let him then saw the rod across the centre, and the sound is no longer transmitted. Hence, he will simply have to place his lathe on a platform which has no contact with the boarded floor, and the noise of his lathe would, I think, be so far diminished as to leave little ground of complaint from his next-door neighbour. Inasmuch, however, as brickwork is also, to some extent, a transmitter of sound, I should recommend that the timbers supporting the platform should have some elastic or soft material placed between them and the wall, on which they would rest. The transmission of sound from floor to floor and house to house is a very important question, and I am surprised that it has not received more attention in the columns of the "E.M." than it has done. I find by experience that a party wall of 14in. in thickness does not prevent the sound of a piano being heard from an adjoining house, and, with an attempt to obviate this, I am about to try the experiment of building the party wall of a pair of semi-detached houses in two thicknesses, leaving a clear space of 9in. between the two houses, covered only by the continuous roof at the top, and iron gratings in the front and back walls. I am of opinion that the outer walls of the kitchen, and other heated flues, being only 4½in. thick, will cause such a rush of wind through this 9in. space as will carry with it any amount of sound which might otherwise be heard from one house to the other.—Z. A.

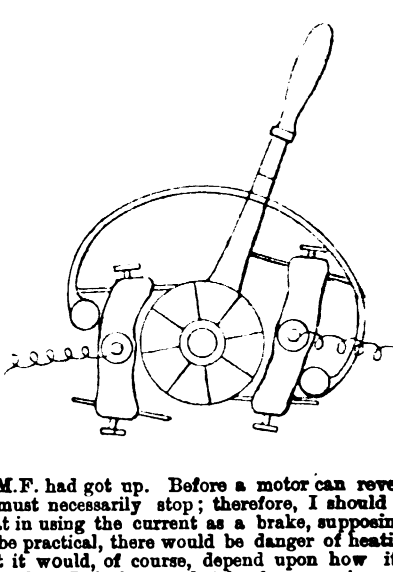
[57233.]—**Fret Saw.**—If possible, get an old sewing machine and table, as some parts of the machine will come useful. If you are unable, you would require to make a table and a corresponding arrangement to what I am about to describe. I bought an old style Wheeler and Wilson machine and table for a few shillings, and decided to make the fret machine of mahogany. The dimensions given are those of my own when finished; but, of course, you can alter them if you wish. Get two pieces of 1in. mahogany, 4ft. by 3in., and two 2ft. by 3in. Bolt one long piece flat on the table so that the centre will be about 2 or 3in. on one side of the hole through which the belt comes. (You will see reason and distance presently.) Dovetail the two short pieces into the ends of this piece, making them fixtures; or, if you wish it portable, a screw through the dovetails would answer. The two short pieces are now upright. Into the tops of these dovetail the second long piece, making it a tight fit, but movable. You have now the stand in which the saw frame will work. Next take two pieces of mahogany 3ft. 9in. by 2in., and two 12in. by 1¼in. The two long pieces must be planed so that they may taper from the middle to each end, keeping one side of each straight, and making the ends 1in. and the middle 1¾in. deep. These four pieces are for the saw frame. Dovetail them or fasten them at the corners with squares on the face. I have both, finding the dovetails hardly kept it stiff enough. All the straight edges of these pieces must be inward. Next come the guides for this frame. Get two round ½in. iron bars about 21in. long. Make them as smooth as you can. Then in the bottom corners of the stand fix two blocks, and 1¼in. from the uprights drill a hole in each exactly to fit the ends of the rods and about 1¾in. from the front of the stand. Repeat the process on the movable top-piece, but be careful to get the two pairs of holes parallel and perpendicular, or the frame will stick. Now procure four screw eyes, and file them out to slide easily on the rods. Screw these into the back of the short pieces forming the sides of saw-frame, with same care to have them parallel and perpendicular, and seeing that the top and bottom pairs are the same distance apart as rods. Take off the top of stand, slip the eyes on the rods, and replace the top. The frame now ought to slide easily. Now for the movement. Do away with the whole of the old sewing machine except the bed-plate and the pulley on which the belt runs. The axle of this pulley projects from one side of the bed-plate. Fix the bed-plate so that the pulley will be just under the saw-frame (taking care, of course, that the pulley and driving-wheel are in a straight line, though they need not be perpendicular to each other). Now, on the end of the axle fix an eccentric, which should come nearly, but not quite, in the middle of saw-frame. Now connect your saw-frame and eccentric by a rod working on pivots in each. When you work the treadle the frame should slide bodily on the guide rods. It may work a little hard at first, but after a short time will run smoother. Mine has about 1½in. or 2in. stroke. Next, exactly in the middle of top and bottom of saw frame drill holes to take the saw clamps. These should be small rods with the clamp at one end and a screw cut for about 2in. at the other, on which is a wing nut to tighten the saw. You must be careful to get the holes exactly perpendicular, and it is well to have the rod of the clamps square, and working through a square hole in a piece of iron screwed inside of frame to prevent the wood wearing. Now the table for the fret wood. At any height that suits you to the back and front (from end to end) of the stand screw two pieces of mahogany, 2in. deep and exactly level. Get a piece of pitch pine, 3ft. 6in. by 2ft. by ⅜in., and screw it on these supports, so that the frame works outside the ends. I have two crosspieces screwed under mine, and let into the two supports, so making the table stronger. Cut a hole for the saw to pass through. To check the recoil at bottom, I took two cotton reels and sawed them across, to make the four halves. Then two halves were screwed to the front of uprights of stand, and the others to the uprights of frame, so that stout elastic bands passed round them would be stretched before the frame reached bottom of stroke. You would require to suit position of reels to your own machine. I am a young draper, and although very fond of machinery, am unfortunately out of the way of seeing any, so that my description may be prolix enough to try even Job's patience, and you, or some other writer, may be able to suggest improvements. However, I made the machine about two years ago, and have done a good deal of work, sometimes cutting two pieces of ⅜in. walnut at once. The advantages, to my mind, over the two-arm bought machines are larger bearing-surface in table, and the saw working perpendicular with no tendency to swing when turning corners. I cannot recommend any book, having picked up all I know from experience. Two things I can advise—namely, keep your saws tight; and do not crowd the wood on them quicker than they can cut. Faults in these two things are the principal reasons for saws breaking. I enlarge my own patterns, as then I can make any alterations. If you are unable to understand anything, and will advertise your address, I will do anything I can.—E. J. A. B.

[57237.]—**Grooves of Pulleys.**—This was the subject of the second communication that I ever made to the ENGLISH MECHANIC, and involved a sketch. It is to be found in Vol. VIII., Feb. 2nd, 1869, No. 203, p. 460. If the Editor likes to insert it over again, it may go in just as it there stands—at least, as far as the sketch is concerned. I have no objection to writing the directions afresh, if Mr. Editor consents to a reproduction.—J. K. P.

[57244.]—**Dentistry.**—Referring to the remarks of "Dens" and "Vincent," on p. 550, I should like to say that there is no trade—I beg pardon, profession—in which there is more quackery than in that of dentistry. A diligent study of the *Transactions* of the Odontological Society would enable anyone who is already a decent mechanic to become a superior sort of dentist.—A. MALLARD.

[57244.]—**Dentistry.**—I really cannot say that I would advise this querist to make a vulcaniser. I have known these to explode; two instances are within my recollection. The usual pressure when they are in operation is 80lb. or 90lb. to the inch, and they should be tested to 600lb. The fees at the various dental schools are about £50, more or less, and it takes four years to get through, including twelve months at mechanical work under a recognised dentist. Diploma at College of Surgeons (after examination) is £10.—Os.

[57249.]—**Electro-Motor.**—The direction of rotation of a motor depends on the relative positions of the poles of the armature and field-magnets. Merely reversing the current would not reverse the direction, unless the fields were connected up different to the usual way. There is danger of heating by sending the full working current through a motor before its speed, and, consequently, its counter E.M.F. had got up. Before a motor can reverse, it must necessarily stop; therefore, I should say that in using the current as a brake, supposing it to be practical, there would be danger of heating; but it would, of course, depend upon how it is wound. I inclose a sketch of a reversing gear invented by Dr. Hopkinson.—EUGENE BROWN.



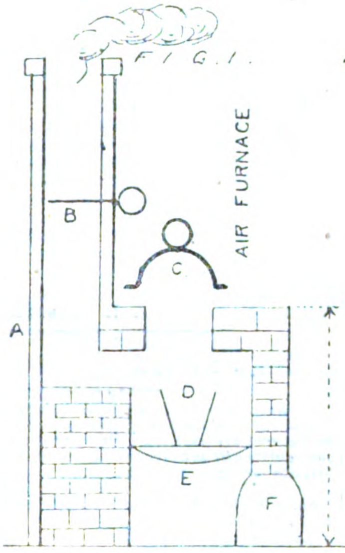
[57251.]—**Agglomerate Blocks.**—"C. D. R." says: "There are quantities of so-called agglomerates that have not a particle of manganese in them." I suppose it would be too much to ask your correspondent to name the dealers in these spurious agglomerates, appending, of course, his own name and address; but he can scarcely have any objection to telling your readers how they may recognise the agglomerates without a particle of manganese, or the means adopted by "C. D. R." to ascertain the truth of his statement.—SILVERTOWN.

[57252.] — **Free Reeds.** — Many thanks to "A. B. C." for his kind attention to this query; but if that gentleman had put the speed of wave of each interval only (4ths and 5ths) a little more simply, I should have understood him better, as I am not an adept at figures. I wish to inform Mr. F. that I am the author of query No. 56676, but not of query 56400, and I know nothing whatever about it. Mr. F. says that a reed may be made to sound a trifle flat under various circumstances. That is just what I have experienced in tuning reeds for various small instruments (steel reeds, of which I have made hundreds) in a temporary tuner which I have made. I have tuned two reeds, unison or octave, without the slightest wave in tuner, and when I put them in the instrument perfectly tight as in tuner, and same size of hole, they don't always sound in tune under any pressure of wind. Has the thickness of reed anything to do with it ?—Amateur Tuner.

[57255.]—**Storage Battery.**—(1) If flat plates are used the best way to keep them in position is to place slips of wood, or vulcanite, or hard substance between each two consecutive plates at the top and bottom, and bind together with two or three elastic bands. Contact is formed by flaps of lead projecting, so that plate and flap is all in one piece. (2) when they are fully charged gas is given off. (3) This depends on which form is used, Faure or Planté. (4) Two cells would only give four volts, and this is not enough to light a 10 candle-power lamp; if 12 cells were used, 10 or more lamps could, I think, be lit.—Bunsen.

[57257.]—**Equatorial Mounting.**—In reply to "Landbird," I would point out that whatever plan of equatorial he may adopt, it is essential that the tangents for slow motions should never be out of gear. The object is, of course, found with the fast motion, which must be obtained by unclamping some kind of screw, which releases the axis at once, and when found can be again clamped instantly, and the object followed by the slow motions of the tangents. If the tangents are taken out of gear to give the fast motion to find the object, which is a frequent method, he will find that while they are being put in again the object will be gone. In a word, the fast motion must be got by a clamping screw, and not by taking out the tangents.—T. Westlake, Fordingbridge.

[57261.]—**Cupola.**—"J. K." had better build a small air-furnace, and use a plumbago pot. If he has the use of a tall chimney, as he speaks of, 30ft. or 40ft. would do first-rate. You can flux with either limestone or broken bottles. With regard to the iron, I would advise him to get new pig-iron, Scotch, Glen Garnock, Welsh pig, Blainhaven, or any other soft pig, and a little machine scrap; old burnt fire bars and the like are only fit for fire bars again. I should recommend you to make a small fan, if you have not got a chimney large enough. You can erect a small chimney, or use the house chimney, and assist with the fan. You can then either make a small blast furnace and do without the pot, or make a square furnace about 3ft. square, with a hole about 15in. square. Connect with chimney, and cover with an iron plate, with fire bars half-way up; use coke. I will give more information if required. I will give you two small sketches of air and blast furnaces :—



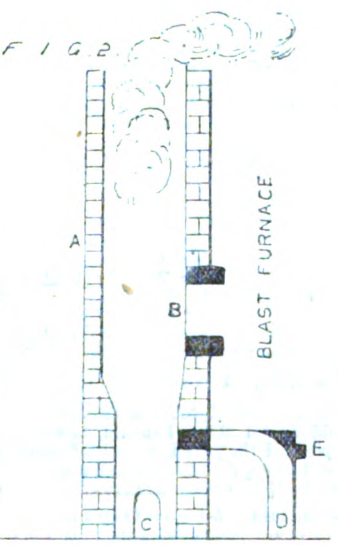


Fig. 1.—A, furnace stack; B, damper; C, cover for furnace; D, plumbago pot; E, fire bars; F, draft-hole; common house chimney will do.

Fig. 2.—A, furnace stack; B, charging hole; C, tapping hole; D, blast pipe; E, peep hole. If it is only for a very small amount of iron, turn the blaze into house chimney, and only make furnace about 24in. deep; cover top over, and turn the draught.

—Sand Rat.

[57265.]—**Bees.**—I should not advise R. Parkes to keep bees in a room, for unless specially built for the purpose there is no end of trouble, and even if built for the purpose it requires more skill and attention than out of doors. All the best beemasters advise the stocks to stand out of doors, and each stock on a separate and independent stand. You can then operate on any one hive without jarring or annoying any of the others. I shall be glad to give you or any other inquirer information, and, by the bye, if you are now beginning, get an old stock which has swarmed once this year, or an early second swarm, for in either case you will get a young queen. Of course you should see that either of the above have, say, 20lb. or 25lb. honey, and a good population, so as to stand through the winter.—J. I. S.

[57269.]—**Surveying Chain.**—"Surveyor" will, I believe, find all the information he wants in Heather's "Mathematical Instruments" (Weale's series). I knew an old surveyor who used to check his chain on a standard line, marked on a garden wall, made of heavy slabs of slate, and always kept by him a lot of ½in. round links to put on or take off from chain as required.—H. A.

[57270.]—**30-Light Dynamo.**—To "W. H. E."—As you will observe by the perusal of my second letter on this subject (which is now in the Editor's hands), the machine is designed to light 45 volt lamps at a speed of 1,500 per minute. To get 50 volts the machine would have to be run at 1,600 per minute. If you object to the speed being so high, you must wind the armature with No. 14 instead of No. 12, when 50 volts would be easily obtainable at a low speed. Any further particulars you may desire I will give with pleasure.—W. H Eaves, Coventry.

[57272.]—**Dynamos for Practical Purposes.**—Although it is not a very practical idea to have an engine to drive a dynamo, which in turn has to drive a Griscom with a loss of about 50 per cent., still, as perhaps this is required more for show than for actual work, I subjoin the following dimensions:—Height of fields, 12in.; dia., 2in. Armature (Pacinotti form), 4in. in dia., 3in. long. Armature wound with No. 16 wire; fields with No. 14. Power required to drive about ¼-horse power. No secondary battery required.—S. Bottone.

[57273.]—**Radius of Curve.**—In the latter part of this question the span is given. Suppose this to be S, then the formula for finding the length of the radius will be—

$$R = \frac{S^2}{8V} + \frac{V}{2}$$

When S = 70ft. and V = 7·5in., R = 11763·75in. If many ordinates are to be calculated with such a large radius, and so small a versed sine, it will be found much less laborious to use the formula—

$$EF = \sqrt{R^2 - ED^2} - (R - V),$$

which differs only in form from that which is given in the question. Putting in this R = 11763·75, and V = 7·5, it reduces to—

$$EF = \sqrt{(11763{\cdot}75)^2 - ED^2} - 11756{\cdot}25.$$

For finding the ordinates for every 2ft., it is now only necessary to make E D successively equal to 24, 48, 72, &c.

Thus for E D = 24 E F = 7·475in.
,, E D = 48 E F = 7·402in.

—Milverton.

[57276.]—**Experiments in Light.**—A Sciopticon or similar lantern. Before you do anything read the admirable articles on the subject, published about three years ago, by Mr. Lewis Wright, in our paper.—S. Bottone.

[57277.]—**Science and Art Department.**—I am too busy at present to take up this subject, but will write next month.—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[57278.]—**Recovering Silver.**—It is quite worth while to recover silver from nitrate bath. Add solution of common salt till no fresh precipitate is observed. The precipitated chloride should be washed, dried, mixed with two parts of carbonate of soda, and a little borax, and well heated in a crucible; when the silver is reduced, the heat should be raised to fuse it. Silver print clippings, if there is a large quantity, should be burnt in a closed stove, the ashes collected and treated with nitric acid; this may be added to the nitrate bath before its treatment. Platinotype clippings should be burnt and boiled with a mixture of nitric and hydrochloric acid; the result is a solution of bichloride of platinum.—C. E. T.

[57278.]—**Recovering Silver and Platinum.**—Silver from old bath. Place clean strips of zinc in the bath as long as liquid blackens clean zinc. Remove what is left of the zinc, throw the whole black-looking mud on a filter, wash with several waters. What remains on the filter is pure silver in a state of fine division. *Platinum.*—Burn the clippings. Treat the ashes first with strong nitric acid, to dissolve any lime, &c. What remains may then be treated with nitro-hydrochloric acid, which will dissolve the platinum. The solution, after filtration through glass-wool or asbestos, may be evaporated until it crystallises as platinum chloride.—S. Bottone.

[57278.]—**Recovering Silver.**—It is most certainly worth while recovering the silver from your bath. You have first to filter the bath solution and add a strong solution of sodium chloride (common salt) until it ceases to precipitate; filter, wash the precipitate, and mix with twice its weight of sodium carbonate. Heat a common fireclay crucible to redness in your furnace, and throw little at a time into some of the above mixture, occasionally stirring until all effervescing ceases; then finally fuse, and on cooling, you will find, by breaking the crucible, a metallic button of silver. Your paper clippings may be treated by reducing to ashes, boiling in nitric acid, filtering, and precipitating with a solution of sodium chloride, and finally treating as above. To extract the platinum from your platinotype paper cuttings, reduce to ashes by heating in an iron pot over a fire; after which, put the residue in a long-necked flask with enough aqua-regia to cover it; boil about thirty minutes, pour off the acids, and replace by fresh. Continue boiling about fifteen minutes longer, then pour off the acids into the first lot, and evaporate down to drive off excess of acids; afterwards precipitate with a solution of ammonium chloride, filter, and wash precipitate with 50 per cent. solution of methylated spirit (the ammonium chloroplatinate here formed being partly soluble in water). The precipitate is then put in a porcelain crucible, and strongly heated until it is reduced to a spongy mass, which is pure platinum. This is afterwards dissolved by heat in aqua-regia, and crystallised; these crystals, being very deliquescent, must be kept in a closely-stoppered bottle, or in a hermetically-sealed tube. If Mr. G. Park should require any further information I will be glad to give him it.—A. Treyer Evans, Monmouthshire.

[57279.]—**Planing.**—Is not F. Shakespear aware that with any job requiring accuracy of workmanship, such as planing a lathe bed, boring a cylinder, surfacing a shaft, &c., once the tools are set in motion for the finishing cut they must not upon any account be stopped until the end is reached, or a ridge would be the certain result, as the tool would cool, and so become a shade shorter? The error is doubled by the work also cooling.—A., Liverpool.

[57279.]—**Planing.**—I never yet paid for any planing done by steam power that I did not go over again for my own satisfaction in my hand planer, or that I had not to true up by filing. Perhaps others are not so particular, and I know that many think because a thing has been planed it must needs be true. It all, or nearly all, depends on how the work is chucked, and whether it is sprung out of truth by being forcibly bolted down. With end-stops and side-stops to prevent the work slipping about, its own weight will often render bolting down quite superfluous.—J. K. P.

[57282.]—**Watch-Work.**—To begin with, "B. L." must get some steel Swiss turns, with a good assortment of runners. This will cost about 10s., and will do almost any job of turning. The tools for cutting are gravers. About half a dozen will be enough. Have one large square, two lozenge, and three small square. Also an assortment of screw-ferrules, five or six assorted sizes. Be very particular as to what edge you get on your gravers, or you will never do a job properly. Go to Grimshaw and Baxter's for them. The whole need not cost more than 14s.—Escapement.

[57284].—**Copper Coating Boiler.**—Iron cannot be electro-coppered with an acid solution by

reason of the very fact mentioned in the query. When iron is placed in a solution of cupric sulphate the iron is dissolved in the acid, and the copper deposited in its place; this mechanically prevents the adhesion of the two metals. The cost of the solutions and batteries required to copper the boiler you have would probably be more than the price of a galvanised iron boiler, which I would advise you to get (that is, if you value a quiet life). —Os.

[57286.]—**Bed Sores.** — Querist does not state where the bed sores are situated; but I presume they are at the lower part of the back. If so, let him place the patient on a semicircular air cushion, concavity downwards, to relieve pressure; keep the sores well dusted with iodoform, and apply salicylic absorbent wool in thick pads, which will avoid the necessity for frequent dressing. This, however, is only treating symptoms. Is there no surgeon within reach who could remove the diseased bone before it kills the patient?—Doctor Medicinæ.

[57286.]—**Bed Sores.**—Some time since I was laid up with rheumatic fever for more than six months, and could not move without assistance. The pain I suffered in my hip and knee-joint from pressure was excruciating. I obtained two springs, such as are used for chairs, sofas, beds, &c. (to be had at the ironmonger's), and had a pad fitted to each end. One I placed between my knees, and the other under my hip-joint, and found considerable relief. "W. S. L." might, try a ligature of indiarubber (to be obtained at most haberdashers'), and fastened with a buckle similar to those used for ladies' belts; this will do away with the inconvenience of knots.—Q. K.

[57290.]—**Woolwich Exam. Question.**—We have here two equations—viz., log. 3 = ·4771213, log. 7 = ·845098; to find two unknown quantities—viz., "M" (the modulus) and log. 11. Apply formula—

$$\log. x = 2\text{M}\left\{\frac{x-1}{x+1} + \frac{1}{3}\left(\frac{x-1}{x+1}\right)^3\text{\&c.}\right\}$$

First—

$$\log. 9 - \log. 7 = \log. \frac{9}{7}$$

$$= 2\text{M}\left(\frac{1}{8} + \frac{1}{3}\cdot\frac{1}{8^3} + \frac{1}{5}\cdot\frac{1}{8^5}\ \text{\&c.}\right)$$

$$= 2\text{M} \times {\cdot}1256571.$$

$$\therefore 2\text{M} = \frac{\log. 9 - \log. 7}{{\cdot}1256571} = \frac{{\cdot}1091446}{{\cdot}1256571} = {\cdot}868591.$$

Again—

$$\log. 11 - \log. 9 = \log. \frac{11}{9}$$

$$= 2\text{M}\left(\frac{1}{10} + \frac{1}{3}\cdot\frac{1}{10^3}\ \text{\&c.}\right)$$

$$= {\cdot}0868591 + {\cdot}0002895 + {\cdot}0000017$$

$$= {\cdot}0871503$$

∴ log. 11 = ·0871503 + ·9542426 = 1·0413929; or 1·041393 to six places. I can't imagine of what use the third logarithm given can be. The whole question seems rather too hard on the examinees.—X. Y. Z.

[57291.]—**Weights of Copper Wire.**—Most electrical works contain tables of weights, &c., of copper wire. Among the best of these are Sprague, Kempe, and "The Electrician's Pocket-Book" (Cassell). Write to King Mendham's for their catalogue, in which much useful information is given.—S. Bottone.

[57291.]—**Weights of Copper Wire.**—Tables of the weights, &c., of electrical wires can be had from most manufacturers and dealers (see advertisements in current number); it is, therefore, perhaps hardly fair to ask space for such a long list as that applied for. A. P. Trotter's patent wire gauge—which was described and figured a few months ago in this paper—will give at one operation the standard wire gauge, and the diameter in decimals of an inch and of a millimètre, of any thickness from No. 6 to No. 40. Also the sectional area in thousandths of a square inch, and formulæ by which weights and resistances can be computed therefrom. The description did not, however, convey a correct idea of the actual size of the gauge, which measures only 2½in. by ½in., and weighs ½oz. —R. T. Lewis.

[57295.]—**Bookbinding.**—"Surveyor" seems to have confused "blocking" with "rounding," making it difficult to understand his meaning. If a book is properly rounded and pressed, it is not likely to become flat again. The reason why the backs are not firm is probably because the books are badly sewn. "Surveyor" would do well to obtain a copy of "Bookbinding for Amateurs," by W. J. E. Crane, 2s. 6d.; publisher, L. U. Gill, 170, Strand, London.—Thos. F. Cass.

[57296.]—**Surveying Chain.**—A chain should most certainly be exactly 66ft. long, and nothing allowed for it not being quite tight or straight, as it should always be so, of course, not pulling it too tight so as to stretch it. The best way for "Surveyor" to test his chain (that is, if he lives in or near London) is to take it to Guildhall, where there is a standard chain gauge laid in the floor of the hall. (I believe gauges are also to be found in several provincial towns.) It is not much good testing (?) it with a tape, even if the tape is new. I suppose "Surveyor" knows that the 66ft. include the handles, as he talks about there being only nine links at either end. Of course, the other two are made up with the handles.—Ikey Mo.

[57298.]—**Faulty Dynamo.**—I cannot, unless you give all details as to the quantity of wire on fields, armature, size of wire, mode of coupling, what experiments have been tried with it, tell what is wrong. Either write to this paper, giving full details, or send it to me, when I will repair it. —S. Bottone, Stanley-road, Carshalton.

[57301.]—**Shaft.**—The diameter of the shaft for the 26in. pinion will be 6·784in. I recommend Anderson's "Strength of Materials and Structures," published by Longmans and Co., London.—A. Gray.

[57303.]—**Electric Motor.**—A small Siemens armature about 6in. long by 2in. in diameter would do the work you require. The fields should be 6in. by 6in. by 1in., with massive pole-pieces and a good heavy iron plate for base. Wind the armature with No. 18. and balance the resistance with No. 16 on the fields.—S. Bottone.

[57306.]—**Dynamo.**—Why not rewind the armature again as a Brush? Or if you find that too difficult, wind as a Pacinotti, which gives excellent results.—S. Bottone.

[57309.]—**Algebraical.**—Consider the pint of water as divided into $n$ equal parts—$n$ being a very large number—and consider these parts, added one at a time to the pint of wine. The first addition may (if $n$ be a large enough number) be considered as expelling $\frac{1}{n}$ of a pint of unmixed wine, leaving $1 - \frac{1}{n}$ of a pint of wine and $\frac{1}{n}$ pint of water. The next addition will expel $\frac{1}{n}$ of $\left(1 - \frac{1}{n}\right)$ wine, leaving $\left(1 - \frac{1}{n}\right)\left(1 - \frac{1}{n}\right)$ wine—*i.e.* $\left(1 - \frac{1}{n}\right)^2$ wine. So after the third addition $\left(1 - \frac{1}{n}\right)^3$ wine will remain. Therefore, after $n$ additions—i.e., the whole pint of water, there will remain of wine

$$\left(1 - \frac{1}{n}\right)^n = 1 - 1 + n.\frac{n-1}{2n^2} - n.\frac{n-1}{2}\cdot\frac{n-2}{3n^3} + = 1 - 1 + \frac{1}{\lfloor 2} - \frac{1}{\lfloor 3} + \text{\&c., if } n \text{ be taken}$$

indefinitely great.

$$= e^{-1}$$

$$= \frac{1}{2{\cdot}71828}$$

This fraction of a pint will therefore be the quantity of wine remaining in the mixture.—F. B. A.

[57312.]—**Trueing Lathe.**—Had I such a job to do I would make a temporary wooden square as long as the shears, then put on the largest face-plate upon mandrel, see that it revolved perfectly true first, and then applying a carefully planed up straight-edge of wood, also in conjunction with aforesaid square, the "biz" would be done.—A., Liverpool.

[57313.]—**Steam Launch.**—Size of boat for engine 3in. by 3in., say 16ft. by 4ft. by 2ft. 1in.; size of vertical boiler for ditto, 1ft. 9in. by 2ft.; propeller—diameter 17in., pitch 16in. This boat would seat three persons; speed, about four and a half to five miles per hour.—O.E., M.E.

[57314.]—**Strength of Gear Wheels (U.Q.)**—You have not given sufficient particulars yet. Assuming that the weight of 5cwt. is hung by a chain from one side of a 10in. drum on the same shaft as the 15in. wheel, the pressure on teeth will be $\frac{5 \times 112 \times 10}{15} = 373\text{lb.}$ If two teeth are always in gear the pressure on each tooth = 186·5lb., and ½in. pitch would do for this. I should, however, make it ¾in. pitch if the gear is to be used much. No shrouding will be required for so small a weight. The wheels may be 1½in. wide.—Glatton.

[57315].—**Botanical.**—All sorts of paper is used; it depends greatly on length of purse. A thick printing paper will do very well, demy size. For book, get Bentham's "Flora"; this, with Balfour's or Henfrey's "Botany," will greatly assist you.—Os.

[57316.]—**Turbine.**—The best turbine is considered to be that invented by Professor Thomson. There are a great many others made, especially in America, but none give so great a percentage of efficiency as this one. If "Jakes" advertises his address I shall be pleased to give him further particulars. I may add I am not interested in the manufacture of the turbine.—Engineer, London.

[57317.]—**Scarlet Fever.**—From personal experience, an efficacious and indestructive method of disinfecting rooms, bedding, &c., is a small fire—composed of paper, cinders, lumps of common brimstone, and lucifer matches—placed in a fire basket or any utensil that will resist heat, and stood on any old tray or zinc in centre of room; bedding, &c., to be about, that the fumes can penetrate, but away from danger of ignition; windows and register closed. After setting light to fire, shut door and lay wet cloth at the bottom to prevent the sulphurous smoke escaping. It does not discolour, but gilt frames should be removed. It is a searching remedy, destroying the infection in the flakes of skin from the peeling. It was recommended by the physician who attended a child of mine in scarlet fever away from home, and we returned to a family of five children who happily did not catch the illness.—Jane Wrenn.

[57317.] — **Scarlet Fever.** — It is difficult to understand exactly what the querist means by the infection of scarlet fever being conveyed in milk. Under certain conditions, it decidedly can be conveyed in milk. If milk has been kept in a room in which scarlet fever is present, such milk is certainly not to be regarded as safe if introduced into the human stomach. All liquids have a tendency to attract impure matter from the air, which is proved by water becoming stagnant if allowed to remain unused. The infection from scarlet fever, like that from other infectious diseases, can be transferred from one person, or place, to another, in various ways, and under various circumstances. Condy's fluid is one of the best-known disinfectants, and full directions for its different uses in disinfecting is to be found on the outside of the bottle.—G. Fryer.

[57317.]—**Scarlet Fever.**—Contagium can be, and has been in several cases, conveyed in milk. The clothes used by the patient, and bedding, when it can be done, should be steeped in chloralum or carbolic acid solution for an hour, then boiled, and hung on lines in the open air. Chloralum is best, as it is non-poisonous and cheap. The bed and other articles which cannot be washed, should be fumigated with sulphurous anhydride, or, better still, when it can be done, exposed in a disinfecting chamber to a temperature of 240° F. for one hour. The doors, windows, &c., of the room should be closed, and ½lb. of sulphur burned in it over a pail of water; the room should then have free ventilation, the ceiling be whitewashed, the paper stripped from the walls and burned. The furniture and paint should be washed with soap and weak solution of chloride of lime.—Temeraire.

[57317.]—**Scarlet Fever.**—There are several methods of disinfecting rooms by gases, &c.; the best seems to be by sulphurous acid. Shut the windows, doors, and chimney, and stop up all the chinks, &c., with paper. Get two tubs of water, put two sticks across them, and saucer on the top; into each saucer put 1½lb. of sulphur, put red-hot coals into them, and get out of the room as fast as you can. When outside, stop up cracks of the door you came out at by putting rugs and mats against it. Leave the room alone for 24 hours, then open the door, rush in, and open the windows. Leave the windows open for 24 hours more, keep letting in plenty of fresh air, wash ceiling and walls with solution of chloride of lime, 2oz. to 2 gallons of water. Sulphuring a room disinfects bedding, furniture, and everything in the room; but it is well to have everything baked if possible, and in severe cases it is better to burn as much as possible. The clothes may be washed in Condy's fluid till the fluid ceases to change colour; when the fluid is clear it is disinfected (even drinking glasses ought to be disinfected). The clothes may be baked (not on metal plates) at a temperature of 220° C. Everything ought to be freely exposed to the air, which is a good disinfectant. There is no doubt whatever the infection of scarlet fever can be conveyed in milk. Many cases have been known in which it was so.—R. A. R. Bennett.

## UNANSWERED QUERIES.

# QUERIES.

◆◆◆

[57320.]—**Model Dynamo.**—I wish to make a model dynamo after the Edison style, big enough to light a three c.p. lamp. Will anyone kindly give me size of F.M.'s and armature, and quantities of wire, &c.?—Silly Billy.

[57321.]—**Webster Condenser.**—I wish to make a Webster condenser. Will someone kindly give radii of curves, and arrangement of lenses?—Draco.

[57322.]—**Violoncello.**—Would any readers give the dimensions for a full-size cello, give length of neck, and say best kind of wood to use?—C. Leech.

[57323.]—**Restoring Clock Case.**—Will any of our kind readers tell me how I can restore an old dead gilt clock case? The case is of a French make, and made of brass.—Horological Tommy.

[57324.]—**To Mr. Bottone.**—I have wound the cog armature of my Gramme with No. 18 wire; it is covered first with silk and then with cotton; a telegraph engineer has tested its resistance, which he finds to be 1·1603 B.A. units; the resistance was taken at temp. 75°. What quantity of wire, and size, shall I require for the four field-magnet bars of the original Gramme form, to be wound in series arrangement?—Tyro.

[57325.]—**Atoms**—I would feel very grateful to any reader who would suggest some graphic method for illustrating atomic vibrations, or give details of the experiment with floating magnets described by Capt. Abney, in No. 1063, "Photography and the Spectroscope," page 494, so as to enable me to construct the arrangement?—P. B. F.

[57326.]—**Pattern Making.**—Would "Invicta" oblige me, or any other gentleman, by saying how to make a lathe gap bed so that the moulder will have no difficulty in moulding the pattern; also, the best way so that he can release it from the sand? Length of bed, 3in. by 6in, 4½in. across face, 5in. deep, of the screw-cutting type.—Iron.

[57327.]—**Fire-proof Composition.**—Would any reader please give component parts of a good fire-clay—metallic fire-clay or asbestos composition—which can be plastered on each side of an iron plate, studded with projections to help hold the composition on—a composition which would stand a fairish blow with the poker without cracking or breaking off? The plate will be placed in a furnace and required to keep a blood-red heat. How long might such plate last?—Fire-clay.

[57328.]—**Tinman's Tools.**—I should feel extremely obliged if any reader of the "E. M." would name the tools required in a tinman's shop, and expound their use. This would be very interesting to some of our readers. Please say the best method for tempering mason's tools?—M. H.

[57329.]—**Engine Stop-valve.**—In an ordinary steam stop-valve, should the steam be admitted to the upper or under side of the valve? I have heard it argued both ways. Which is correct, and why?—Junior D.

[57330.]—**Legal.**—A minor contracts a debt—not for a necessity—and the bill being sent to him pays part, holding the receipts for the same. After a time the creditor declares that the debt was contracted by the minor's parent, through the son, and threatens proceedings. Until this time no claim has been made on the parent, but repeated applications have been sent to the son for his account. Can proceedings be taken against creditor for attempting to extort money on false pretences?—Up a Tree.

[57331.]—**Crystals of Gold.**—Will any friend let me know the various crystals of gold (other than perchloride), and how I may prepare them?—F. L.

[57332.]—**Manufacture of Aluminium.**—Will some of our chemical friends (Messrs. Grey, Allen, &c.) kindly say why is it necessary to use the double chloride of aluminium and sodium in the preparation of aluminium? Why would not the chloride of aluminium do by itself? The metal can be prepared from the chloride alone. What part does the chloride of sodium play in the process?—Ex-Garrison Gunner.

[57333.]—**Solder.**—What is the difference between "hard" and "soft," solder, and how are they made? The solder one buys in the shops is, as a rule, unsatisfactory, and I find that tinsmiths in general prefer to make their own themselves. I saw one at work some time ago, and he kept casting and recasting it, pouring it out on a flag and watching it till he thought it satisfactory. They also keep the secret of making it to themselves.—Ex-Garrison Gunner.

[57334.]—**Heinrich Dynamo Machine.**—Will someone kindly say if these dynamos are used anywhere, as I have not seen or heard of any? From a description on page 28, Vol. XXXIII, the principle is spoken of as being very efficient, and in the following number an article appeared giving the theoretical reasons why this form of armature is superior to the solid Gramme or Pacinotti. Have they proved satisfactory?—A. W. Lambert.

[57335.]—**Battery.**—I have two trough batteries (only one of which I propose to use at once) of 7 cells, about 30in. by 15in. by 14in., and purpose lighting my study with one of the above, using four 10-c.p. lamps of 10 volts each, coupling the 7 cells in series, but am at a loss as to best way of charging. I propose to use nitrate of soda (as the zincs will not need removing when battery is not in use) in porous cell, with carbons and sulphuric acid in outer cell. On page 210, Vol. XXXIX. there is a battery described much the same as mine, having two zincs and two carbons. Would "Electrical Engineer," or some other kind person, tell me the quantity of nitrate of soda per gallon of water for carbon cells and the same for sulphuric in outer cell with the zincs? Any other way of charging battery without polarisation whilst disconnected, as also duration of working of charge, will be gratefully received by—A Sceptic.

[57336.]—**Eccentric for Loco. Engine.**—Will one of your readers kindly inform me, as I am only a novice, the proper way to set out an eccentric for a locomotive engine, showing how he gets his sizes and the rule? In a book I have (by Michael Reynolds) he gives a size, for instance, of the valve gear as follows: Travel of valve 4in., throw of eccentric 5½in. by 2⅞in., breadth of eccentric 2¼in., lead ⅛in., lap outside ⅞in.; also in another place he mentions the radius as being 2¼in., and the total throw as 5in. Will you kindly explain the meaning of the terms the "throw" and the "radius" as given?—Milo.

[57337.]—**Carbolineum.**—An oil which forms an excellent preservative for fishing nets, or wooden piles driven in water, which it materially hardens, but does not close up the pores. In use in Germany, especially for nets. Can any of "Ours" speak of it?—P. P.

[57338.]—**Canadian Mounted Police.**—Will some reader kindly give information about the above force? What are the necessary qualifications, mode of entry, pay, &c., &c.? Any information will greatly oblige.—North-West.

[57339.]—**Diffraction Gratings.**—I should be much obliged if any correspondent would inform me of the advantages and disadvantages of diffraction gratings, as compared with prisms for viewing the solar spectrum, &c.?—Rosicrucian.

[57340.]—**Organ Tuning.**—Will one of the organ correspondents of the English Mechanic kindly inform me what the usual rate of charge for organ tuning and regulating is, in England (when taken by the year), and the number of visits required to be paid annually—say organ to consist of two manuals and reeds, and about 15 to 20 stops? Much doubt on the subject exists here, and any information from one acquainted with the practice in England would be gladly received by others as well as myself in this colony, directly or indirectly concerned in the question.—R. Cecil Clifton, Perth, W. A.

[57341.]—**Polariscope—Soleil—Laurent.**—I have a polariscope by Soleil (Duboscq), which is constructed on the principle of the transition tint, teint de passage, produced by means of a bi-quartz, with the usual arrangements of Nicol prisms, quartz compensators, &c. Now that the half-shade polariscope of Laurent is coming so much into use, I would like to contrive some arrangement by which I could permanently alter the Soleil to a Laurent, or even preferably use it as either. I think the removal of the bi-quartz, and substitution of a cell containing the half-quartz plate of the Laurent might do it. Will some of our scientific correspondents help me? I have Landholt's book, and have carefully read Glazebrook and Shaw's "Practical Physics," and Glazebrook's "Physical Optics," from which I think such a substitution as I suggest is possible. I shall be very greatly obliged for any kind assistance.—Chemicus.

[57342.]—**Carbon Moulds.**—Can any readers of the "E. M." give me any instructions how those moulds of charcoal or coke dust are made, the same that were on sale at the Paris Exhibition, 1878, and are used for making glass bottles, globes, &c., as they are so much cheaper than brass or iron?—E. F. H., Goos, Russia.

[57343.]—**Cupric Oxide.**—Would some of our kind readers please say which is the cheapest way of obtaining this oxide on a large scale?—E. F. H., Goos, Russia.

[57344.]—**Punching Round Washers.**—Can any of your readers describe a punching machine made to punch round washers, at one stroke of the machine?—Scotch Mechanic.

[57345.]—**Electrical Weather Vane.**—Will F. M. Rogers please describe the mechanism of the above? See sketch on p. 411.—Glatton.

[57346.]—**Jewellery.**—Can any reader tell me how to make (1) the mounting for a cat's-eye breast pin? (2) Silver head for walking cane?—Demetrius.

[57347.]—**Heating Surface—Condensed Steam, &c.**—Will some correspondent kindly help me with the following information, viz.:—What is meant by the expression "train mile"? When the quantity of heating surface of locomotive tubes and the diameter and length of tubes has been decided upon, how can the number of tubes be found? Give a worked example, and say if all or only a portion of the tube heating surface of locomotives is taken as effective? What rule can I use to obtain the length of pipe, or the surface of a series of pipes to conduct the exhaust steam from a 12in. diameter cylinder non-condensing steam engine, with 18in. length of stroke, steam on pressure-gauge of boiler, 65lb. per square inch? And how can I find the diameter and number of length of tubes required? The length of each tube to be about 4ft., and the diameter from ⅞in. to 1in., would be the most convenient sizes to use. Kindly give examples.—Thanet.

[57348.]—**Back-ache.**—This appears to be no uncommon form of complaint with mechanics of middle age. I am troubled with it, and if any subscriber could give reliable counsel for its relief, I think he would receive the thanks of many. I am a machinist, 35 years old, very thin, and otherwise fairly healthy. The shop I work in is no better or worse than most, and I live as well as I can, and drink very little and smoke less. The pain is seldom acute, but generally a dull, aching, stiff, unpliant sort of feeling, which the moving and lifting castings, or whatever the job in hand is, aggravates, and the system feels rather depressed and quickly tired. I have had it more or less for the last two years. I have been advised to try this, and to try that, and have also been told it is not curable, and is a symptom of the decline of the bodily powers, commonly called the approach of old age. What says the English Mechanic? I may add that it is rather worse on first rising in the morning, and generally worse on Mondays after the Sunday's rest, and doctors don't seem to understand.—Hammer and Tongs.

[57349.]—**Gramme Dynamo.**—Will any person give me directions and measurements for making the above to light six 10-c.p. Swan incandescent lamps? Also the size of a small steam-engine to drive the same?—W. Laurie.

[57350.]—**Butter Fat in Cream.**—Can any correspondent inform me if there is any ready method known for estimating roughly, the quantity of butter fat in cream, or give me suggestions in what direction experiments should be made to discover such a method? I am working with the hydrometer at present, but can get no definite results.—Fresh Butter.

[57351.]—**Ascent of Bullet.**—The initial velocity of a Martini-Henry bullet is 1,320ft. per second; if fired vertically in vacuo, it would ascend 27,225ft. or rather over five miles. Can any reader give the answer, taking into account the resistance of the air?—W. John Grey, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[57352.]—**Dynamo.**—To Mr. Bottone.—I have a dynamo that gives 40 volts. Could you be so kind as to inform me what resistance to place in circuit, so as to bring the E.M.F., down to 30, 20, 10, and 5 volts between the poles.—F. G.

[57353.]—**Skewer-Making Machine.**—Would some kind correspondent favour me with instructions how to construct a machine for making wood skewers?—Amateur.

[57354.]—**Surveying.**—Will some reader kindly recommend a good textbook on surveying?—J.

[57355.]—**Small Dynamo Worked by Town's Water.**—In the Inventions Exhibition, I am told there is a small dynamo or magneto machine, attached to a kind of turbine, worked by town's water supply, so that one can have electricity by turning on the water tap. Can any brother reader give particulars of this machine and how to construct a small turbine for town's pressure?—A Gormless Lad.

[57356.]—**Storage Battery.**—To "C. D. R."—I propose to charge my battery with a small Gramme dynamo. Will you kindly tell me how I can make a storage battery that will light a 10 c.p. Swan lamp? I bought No. 1016 of the "E.M." but it only gives directions for lighting small microscopic lamps, so that as plain an explanation as possible will be esteemed a favour?—W. Laurie.

[57357.]—**Tinfoil.**—To "Invicta" or Others.—I will be much obliged if any one can tell me the reason of tinfoil geting white after it is rubbed with mercury, and put on the glass? It seems all right for a while, but after they are put up on their edge, the silvering comes all off; but if I put more mercury on, and draw the glass off, and put it on again, it will do; but I want it right at once. The foil is 2, B, and thicker sometimes. How long should the mercury be on before I put the glass on it? Also it gets blistered, and air goes underneath? Is it the mercury or tinfoil that is bad?—Foil.

[57358.]—**Putting Bars in Lancashire Boiler**—Will any kind reader please inform me the best way of putting new fire bars in Lancashire boiler? What I want to know is, how much play there should be endways, and should they fit tight across furnace? The flues are 2ft. wide, and furnace about 5½ft. long; the bars are at present in two lengths, with cross-bar in centre; they rest on dead plate at each end, and hook in centre bar, but they buckle in one length, and drop off dead plate the other. The bars don't half wear out before we are obliged to have new ones. I trust some of our readers will give me a few hints, and oblige.—One Anxious to Learn.

[57359.]—**Putting New Cotton in Lubricators.**—Will any of "ours" please inform me of the best way of putting fresh cotton in lubricators, and do you put more or less cotton for using the oil faster?—and oblige One Anxious to Learn.

[57360.]—**Chronometer Balance.**—Will Sir E. E. Beckett, or some reader, kindly answer the following, it being asked in the honours grade in watch and clock making examination of the City and Guilds Institute? In what way would a chronometer balance be affected on being transferred from the poles ($g = 32·25$) to the equator ($g = 32·09$), the temperature being assumed to remain the same.—G. W.

[57361.]—**Laying out Sheet Iron and Boiler Work.**—I am pleased to see the abridged article on the above subject in this week's "E.M.," particularly as I am just in need of assistance in boiler work, having to order plates for a new boiler of the old cylindrical type, with round ends to be formed in the usual way of seven plates, six tapering from the circumference towards the apex, and one circular to form the extreme end. Will any of "ours" kindly give an example in projection, that will enable me to find the proper curves or lines to cut the flat plates to, so as to form the hemispherical ends of a boiler, 6ft. diameter? Such an example, I have no doubt, will be of great service to many.—Enquirer.

[57362.]—**Engine.**—I have a pair of condensing engines, 40in. cylinder, 6ft. stroke, cutting off steam at 3-10ths of stroke. If I increase my boiler pressure, and cut off steam at 1-10th of stroke, how much more strain will put on my wheel? It is 20ft. diameter, and pitch of tooth 3 15-16th.—Young Engineer.

[57363.]—**Lamp for Soldering.**—To Mr. Bottone, or Others.—Can you please tell me of any kind of lamp suitable for soldering under following circumstances? I have a small carpenter's workshop (amateur), but cannot have a fire, nor can I have the gas without more expense than I can go to. It must be something safe and easily managed, as my friends are afraid of fire in the workshop? I am thinking of following some of your electrical articles.—E. J. A. B.

[57364.]—**Electrical Veterinary Oil.**—Can any reader inform me of the composition of this oil, and the method of preparation?—Alto Petit.

[57365.]—**Phosphor Tin.**—Which is the best method for estimating phosphorus in this alloy?—Alto Petit.

[57366.]—**Chewalla.**—What is this prepared from?—Alto Petit.

[57367.]—**Deflector.**—Could any of our railway experts state why an iron deflector (allowing the water in the boiler to circulate through it) is not used in place of the ordinary brick arch in loco. fireboxes, as it would appear to me to add considerably to the heating surface of the boiler?—W. S., and Mac.

[57368.]—**Organic Chemistry.**—Can anyone inform me what is the acid produced by the action of the fungus called the ginger-beer plant, upon the sugar in which its growth takes place? Evidently carbonic-acid gas is produced, and another acid resembling citric or tartaric in flavour, apparently no alcohol; but I have no means at home of analysing the resulting mixture?—F. B. A.

[57369.] — **Locksprings.** — What is the simplest method of improving the temper of common locksprings? Marchen.

[57370.]—**To "Sigma."**—I have your book "Electricity"; but I cannot make out from it what I want particularly to know—how many square inches of zinc are required to give one ampère of current through one or more ohms' resistance in each kind of battery? Will you kindly put me in the way of getting this?—Finem Respice.

[57371.]—**Extra Currents.**—In "Experimenter's," reply to No. 56649, regarding extra currents, he shows that the "break secondary" (direct) splits in the multiple arc arrangement of the coils, the parts meeting at a point, and because they are equal and opposite destroy each other. How the destruction of the two parts is thus effected I fail to see? Is it not the case that in the series arrangement the "break secondary" traverses each coil separately, whereas in the multiple arc arrangement, half of this current traverses each coil at the same time; and thus the demagnetisation of the cores is quickened in the latter arrangement to a much greater extent than in the former?—Telegraphist.

[57372.]—**Organ Pipes.**—I have four octaves open diapason wood pipes C to C, which I want to continue down to CC. Would any of the musical gentlemen to "Ours," inform me whether, by continuing the scale down to CC, but reducing the length by half, and using stoppers, obtain the correct note, as I have not height enough for the full length of the CC pipes?—Pipes.

[57373.] — **"Genuine Humber" Tricycle.** — I shall feel greatly obliged if any of my brother-readers can give me some information as to the possibility of fitting Bown's ball bearings to the above. My bearings (both main shaft and pedal shafts) have gone entirely wrong: the cheeks between which the balls run are soft in places and consequently have worn oval, and the soft parts have burred up to such an extent that it is no longer possible to tighten them up. As I have only had the machine since February last, it is rather annoying, to say the least of it. I may say that I am a practical man, and that I shall have no difficulty in carrying out any instructions which may be given on the subject?—Cyclist.

[57374.]—**Portland Cement.**—Will any of your chemical correspondents oblige me with the most approved method of analysis of Portland cement; and also of the slurry during the process of manufacture? I have looked through all the back numbers, but cannot find it given anywhere.—Zax.

[57375.]—**Heating Greenhouse.**—I have a small greenhouse which I endeavoured to heat during the winter with a small round upright, slow-combustion stove (Portaway's No. 2), which I fed with small, crushed coke. As far as heat was concerned all was well, but the dust which it created when cleared out was more than I could tolerate; so I took out the stove and placed it in an archway which passes under one end of the greenhouse, and then brought the flue (3½in. cast-iron rainwater pipe) through the floor and along its entire length and then out through the roof, thinking, as the greenhouse is very small, this would afford sufficient heat. But I found that unless the stove was full of fire, I could not get any heat in the greenhouse, although it warmed the archway beautifully. There was also a very close smell from the pipes. Would it be possible to put a coil of small-bore pipe inside the stove taking out the fireclay, and carrying the pipe through the floor of the greenhouse to a tank at the end with a return pipe. The coil could not go to the bottom of the stove by 4in., on account of the draught door? There would be room for a coil 12in. deep, and 9¾in. external diameter. What I want to know is would there be room for sufficient fuel to keep it going without attention at night? What is the minimum bore which would work freely? (the smallest possible would, with the hot water in tank, be sufficient to heat the house). Should the coils be close together or a space between them? Would ordinary wrought-iron steam-pipe do? The distance from the stove to the tank is about 12ft. Or can any of our practical men suggest any other plan of using the stove? I would rather not use the coil if I can achieve the result in a simpler manner.—A, H. H.

[57376.]—**Electricity in the Microscope.**—At some of the scientific gatherings of the year there has been on exhibition a slide in which, with the microscope, has been shown the zig-zag sparks of the electric current. Will some of my friends tell me how to make such a slide, and say if I am to use with it a spark coil?—E. B. Fennessy.

A new appliance for drying and superheating steam has been devised for multitubular boilers by Max Gehre, of Hanover. As superheaters in the firebox act unequally, and are liable to great strain, the Gehre apparatus is placed in the smoke-box, being composed of a chest traversed by tubes forming a continuation of those in the boiler, but of rather larger diameter. The steam is thus superheated by contact with the outsides of the tubes and the inside of the chest, both heated by the products of combustion.

Dr. C. Lang, in *Biedermann's Central Blatt für Agrikultur-Chemie*, lays down the law that night frosts are only to be feared when the dew point lies below the freezing point of water.

A temperature of 570 deg. will produce a dark blue colour on polished steel, and 590 deg. a pale blue. Oil or grease of any kind will answer for drawing the temper of cutlery. The temper for lancets is obtained at 430 deg. Fahr., axes at 500 deg., swords and watch-springs at 530 deg., small saws at 570 deg., and large saws at 590 deg. Copper-coloured spots are not produced by tempering, but they may be obtained on the polished surface of steel by immersing the article in a solution of sulphate of copper.

# ANSWERS TO CORRESPONDENTS.

⁂ *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

## HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Aug. 26th, and unacknowledged elsewhere:—

K. B. Williams.—W. F. Stanley.—W. G. Stewart.—W. Hayward.—Foster and Williams.—J. Zaehnsdorf.—J. L. —J. I. S.—A Subscriber.—O. J. L.—Mechanicus.—W. Bundy.—H. Dowsett.—R. Jackson.—Co-Operative. —Young Beginner.—G. A. Bolton.—Chesterfield.—H. —Annie.—J. Martin.—An Ink-wirer.—J. Vinicombe.—P. W. Stanley.—Lancashire.—A. J. D., Cambridge.—Tyrol.—P. W. R.—A Marine Engineer.—John Grant. —M. H.—A Friend of the Bone Shaker.—J. Joslin.

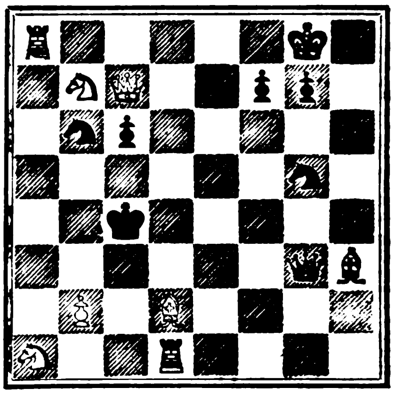
W. (We think you will find a work of the kind published at *The Field* office, Strand, W.C.)—G. Fryer. (The query is unsuitable. No one knows how the people Columbus found in America got there. Probably from China or the North by way of Alaska.)—Jno. J. Latham. (If your signature was "One in Despair," you were answered in the number for Aug. 14, and referred to p. 456. At any rate, as you have taken "the 'E. M.' so long a time," it is strange that you do not seem to be aware that a great deal about loss of hair has been inserted.)—S. B. R. M. (See p. 520, No. 749, for the boot polish or harness blacking.)—S. Thomson. (Scarcely of sufficient interest, and not likely to be answered.)—Walter. (The gas will not get in if the pressure is always 30lb.; but the water is sometimes turned off and then gas enters by the leaks. 2. What a water company is "obliged" to do depends entirely on the special Act under which it works. It is strange that there is no proviso compelling the company to supply water for fire-extinguishing purposes. 3. We believe they are issued by the Queen's printers, East Harding-street, E.C.; but those of the more important are published in the newspapers.)—A Hopeful Student, G. A., H. W. (We have frequently stated that the guide to the Whitworth Scholarships can be obtained from the secretary of the Science and Art Department, South Kensington, price 6d. See answer to "A. M." last week.)—R. B. S. (We believe it is out of print; but ask the booksellers. As a rule they know.)—T. E. W. (Query against the rules; but the agents mentioned are no doubt Wallis, Euston-road, N.W., and Dawkins, Charterhouse-street, E.C.)—Seeker. (Query not suitable, and it is doubtful whethey anyone has taken the trouble to count them.) —J. Slack. (The process you describe is lithography; but copies can be taken in aniline ink from a surface made up of glue 1 part, glycerine 4 parts, and sufficient whiting to colour. See indices for several other copying processes.)—W. M. B. (The numbers are out of print. 2. Vellum is usually understood to be picked skins of parchment, those made from the skins of young animals. The process is described in any cyclopædia.) —An Interested Reader. (It would do for bell-ringing; but the same arrangement is better with caustic potash. See "Tinpot Battery" in indices, and p. 5, No. 885.) — Ignorance. (Query too vague. What is it you wish to know? Electric bells have been described over and over again.) — Hydrogen. (Look in any textbook.)—G. H. (Better purchase a piece; but direction for silvering glass will be found in many back numbers.)—Esse. (Not necessarily, but it seems to be in your case. Why not keep oils of the kind in a well-ventilated place.)—Student. (Cement it on with marine glue or shellac, or rivet it.)—Muneor. (For welding cast steel see p. 338, Vol. XXXV.; pp. 337, 465, Vol. XXXII., and so on. Borax or plaster of Paris is generally used.) —Polisher. (Hydrofluoric. See p. 156, No. 891, and p. 376, No. 927.)—F. E. Baxter. (So far as we know nothing more than a simple writing-pad or book with firm sides, or a portable desk resting on a tripod. Sporting reporters are those who have most occasion to use such appliances, and an application to one of the papers which report racing will probably bring forth the desired information.)—Roots. (Any bookseller can help you to the work you require, for any good arithmetic contains the rules.)—W. J. H. (See a textbook of chemistry. It is a powerful narcotic.)—Allan Kaye. (We do not know of any "work" on the subject; but you can find designs for such machines in our columns.)—Enquirer. (Try "Electric Illumination," by J. Dredge, published at 35, Bedford-street, Covent-garden.)—V. (No book on such a subject, but the processes are described in the cyclopædias.)—A. Madocks. (Ivory black, otherwise "drop black," used with gold size and varnish. Any of the large colourmen will supply you with the article ready prepared.)—Economy. (Of course it would be cheaper, because you would save the manufacturer's profit. Get a catalogue from Barnet and Foster as advertised on front page.)—Escapement. (Price varies according to quality. Inquire of Messrs. Hughes, Drury-lane, W.C.) —M.M.I.Sc.S. (We should think it just the reverse, and that some mistake has been made; but why not write to the paper in which it appeared?)—A Reader. (For a metronome, see p. 216, No. 841.)—Sufferer. (For treatment for jaundice, see pp. 242, 264, 284, 310, 357, 381, Vol. XXXI.)—P. F. (Scrape the horns well, then use powdered charcoal and oil on a bit of rag or leather until the marks of the scraper are removed. Put the final polish on with rouge and water and the hand. Of course, you can use a buff in the lathe, if you have one.)—H. R. H. (It is a swindle, and we have stopped all the advertisements. A warrant is out for the apprehension of the advertiser.)—Ichi Ban. (The name of the firm still appears in the London Directory, but we know nothing of them; and we do not think the correspondent you mention is likely to know much about missing Japanese registered letters.)

# CHESS.

All Communications for this department must be addressed to J. Pierce, Langley House, Dorking.

## PROBLEM DCCCCLIV—Check.

*Black.*



*White.* [9+7

White to play and mate in three moves.

Solution to 952.

| *White.* | *Black.* |
|---|---|
| 1. R-Q 5 | 1. P. takes R (*a*) |
| 2. Kt-Q 4 | 2. Anything |
| 3. Q or P mates | |
| | (*a*) 1. K takes R (*b*) |
| 2. Q takes K P (ch) &c. | |
| | (*b*) 1. Q takes R (*c*) |
| 2. Q-K 3 (ch) &c. | |
| | (*c*) 1. Q-Q 3 (*d*) |
| 2. Q-R 4 (ch) &c. | |
| | (*d*) 1. Q-Q 5 |
| 2. Kt takes Q, &c. | |

## NOTICES TO CORRESPONDENTS.

Correct solutions to 951 by T. L. Robins, F. A. Vincent, and T. Colson (good).

To 952 by H. Culmer, R. A. Bennett, A. A. E. Lecluse, J. A. Miles (very good and difficult), V. S. Pochin, and A. S. Olver (difficult).

To 953 by A. S. Olver (charming), H. Culmer, E. S., J. A. Miles (accurate but easy), Streetgate, and R. A. Bennett.

T. Colson.—In 952, if 1. $\frac{\text{Q takes P}}{\text{Q-Q 5}}$.

A. A. E. Lecluse.—In answer to your second query—on the whole, yes; yes also to third.

The following modification of the rules of proposed New Game Correspondence Tourney, as given in preceding number, may perhaps be more acceptable:

1. That the number of entries should be limited to twelve.
2. Each player to play simultaneously two games with each opponent.
3. The six who have the highest scores to divide the subscription money between them in proportion to the number of games they have won.
4. If a player retire from Tourney before it is concluded, he shall forfeit his entrance fee.
5. If he retire before half the number of his games are played all would be cancelled; if after, those not played would be scored against him.
6. Time limit for each move, two days.
7. Entrance fee, £1.
8. Each player to play two opponents simultaneously.
9. If a game is drawn it counts half to each player.

**Every Workman** connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words .. .. .. .. .. .. .. | 2 | 6 |
| Every additional eight words .. .. .. .. | 0 | 6 |

Front Page Advertisements Five Shillings for the first 40 words, afterwards 9d. per line. Paragraph advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

| | s. | d. |
|---|---|---|
| Twenty-four words .. .. .. .. .. .. | 0 | 3 |
| For every succeeding Eight Words .. .. .. | 0 | 3 |

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. | d. |
|---|---|---|
| Sixteen words .. .. .. .. .. .. .. | 0 | 6 |
| For every succeeding Eight words .. .. .. | 0 | 6 |

*** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O.'s

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday, to insure insertion in the following Friday's number.

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

## TERMS OF SUBSCRIPTION.

### PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve months, Post Free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII., XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., and XL., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

**Holloway's Pills.**—Typhoid and other Fevers may be arrested in their early stages by a course of these purifying Pills. This medicine controls the circulation, lessens the shivering, and modifies the hot periods. Holloway's Pills relax the parched skin, diminish the excessive thirst, clear the furred tongue, and restore to health.

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words, and 3d. for every succeeding 8 words.*

**Good Value Offered** (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—CAPLATZI, Science Depot, Chenies-street, near British Museum. Established 1862.

**Sixpenny Telegrams.**—We are making these sets expressly for Students of Telegraphy.—SLEDGE, WYATT, and Co.

**Sixpenny Telegrams.**—SLEDGE, WYATT, and Co., Electrical Engineers, 95, Wirtemburg-street, Clapham, S.W.

**Sixpenny Telegrams.**—Number of vacancies will occur for Telegraphic Clerks. Practise at home. Ensure success.

**Sixpenny Telegrams.**—Sounder Set, 30s.—SLEDGE, WYATT, and Co., 95, Wirtemburg-street, Clapham, S.W.

**Water Waste Preventers**, all brass fittings, especially made for strength, 24s.—KNIGHT, Reading-road, Basingstoke.

Valuable **Invention** for Making Waggon Wheels. Large profits guaranteed, by cast iron.—W. LEITH, Glengarnock, Ayrshire.

**Electric Indicators**, Bells, &c. (Royal Letters Patent).—Halbert Works, 27, Penton-place, Pentonville Hill. Price list, trade.

**Electric Pendulum** or Drop Movements, 24s. per doz. Handsome circular 3in. Bell, 4½ mahogany (French polished) base, 5s.—Above.

**Surplus Electric Light Stock.**—Dynamo Machines, Carbons, Zincs, Silk-covered Wire, &c., at exceedingly low prices.—Apply for list to Messrs. THOMPSON, DOWSING, and REW, 4, Queen Victoria-street, E.C.

**Piles.**—Worst cases cured first application. "Indian Ointment," 13 stamps. "New African Tonics." Packets, 60 stamps (in proof for short time, 30.)—THOMAS PALMER, St. Helen's, Auckland, Durham.

**Reflecting Telescope** for sale, first-class 8½-inch Mirror, by With, five eyepieces, wooden tube, and stand, portable, only £14.—E. P. P., 85, Gresham-street, E.C.

**Direct-view Pocket Rainband Spectroscope**, adjustable slit, thirty shillings.—ANGELL, 27, Parkhurst-road, London, N.

Two H.-P. **Launch Boiler**, new, cheap.—RESIDE, Brighouse, Yorks.

The **Unique Hand and Power Drill.** Amateur Drills, 25s., or Castings for Drills, Lathes, Engines, &c.

**Lathe Carriers**, Chucks, Turning Tools. Sample Carrier or Tools, free, 1s.—RESIDE, Brighouse.

5½in. back-geared **Lathe**, 5ft. bed, turned flywheel, roller, treadle motion.—RESIDE, Brighouse.

**Microscope Objectives**, one ⅛th and 1-12th immersion, English lenses, cheap.—EDWARD SWIFT, 105, Myddleton-road, Hornsey.

**Patents, Designs, and Trade Marks.**—For information and moderate charges apply to F. M. ROGERS, 21, Finsbury-pavement.

First-class ⅛ and ¼ for **Histological Research**; also ¼ for brewers.—Below.

**Binocular**, by Baker, concentric glass stage, ¼ and ½, £6.—ALPHA, 1, Bolton Villas, St. Thomas's-road, N.

**Your Photograph Enlarged** to 10in. by 12in. 5s. Artistically painted in oil, 10s. 6d.—G. KEITCH, Artist, Fishponds, Bristol.

**Photographs**, Scottish scenery, 7in. by 4in. size, extraordinary value, 4d. each.—Address, W. FINLAY, 182, Trongate, Glasgow.

**Gelatines** for tracing magic lantern slides, 3¼ size, 4½d. per doz.—Address, W. FINLAY, 182, Trongate, Glasgow.

**Living Microscopic Objects.**—The beautiful Polyzoas Plumatella and Cristatella, tube either, 8 stamps.—WYKES, Alvechurch, Redditch.

**Force Pumps** for Testing and Feeding Model Boilers, 5s.—J. LEECH, South View, Hayfield, Stockport.

Eight horse-power **Portable Engine.** Can be seen working. Reasonable offer accepted.—VOKES, Chalk-lane, Hull.

**Pulvermacher's Rheumatic Belt**, &c., new, cost £3, price £1.—Mr. HITCHMAN, 31, North-street, Ventnor, Isle-of-Wight.

Britannia Company's No, 5 back-geared gap bed **Foot Lathe**, several chucks, &c., new February, price £13.—N. PEARCE, 55, Chesterton-road, Cambridge.

**Diatomaceæ.**—Packet of Peat Bog (Scotland), rich in large forms of Diatoms, post free 1s. 1d.—W. WHITE, 17, York-street, Nottingham.

**Pure Chemicals and Oils** for every branch of manufacture.—H. DUNSFORD, 58, Victoria-street, Liverpool.

**Special Preparation for Cleaning Machinery** by chemical means. Much quicker and cheaper than emery cloth. Agents wanted.—H. DUNSFORD, 58, Victoria-street, Liverpool.

**Model Engine Castings.**—Hard Zinc, rough or finished. Send particulars of requirements. Estimates free.—READER, Woolwich.

**Hard Zinc Castings.**—Substitute for brass, at cheap rates.—CHARLES READER, 20, William-street, Bullfields, Woolwich.

**Lathe**, back-geared, 3in. centres, 3ft. iron bed, saddle traversed by screw, mahogany tool board, complete, £6.—J. COATES, 16, Alma-street, Drypool, Hull.

**Accumulators, Batteries, Bells**, Chemicals, Dynamos, Galvanometers, Lamps, Motors, Wires, Engines, Water Softeners.—CORDNER, ALLEN, and Co.

**Electrical Prices and Tables.** Send stamp for catalogue.—CORDNER, ALLEN, and Co., Limited, 20, Bucklersbury, London.

**Odd Spiral Springs** made to order. Mattress Springs, 9d. per dozen.—JAMES PARISH, 52B, Bard-street, Park, Sheffield.

**Brass Model Engine Castings.**—Rough and finished. See new list, stamp.—WOOD, Dalley-street, Broughton, Manchester.

**Dynamo**, no worse than new, for sale, or exchange for microscope.—A. C. HERVEY, Portchester, Fareham.

**Hand Dynamos**, 30s.; with driving wheel complete, 36s. Warranted.—STEVENS, Waterloo-road, Romford.

Spong's **Double Roller Mincer**, nearly new, cost 25s., price 15s.—E. SIMPSON.

Bateman's **Vertical Copper Boiler**, 9in. high, complete, cost 35s., price 25s.—E. SIMPSON.

Pair 4-horse **Governors**, with bevel gear, 25s.—E. SIMPSON, Engineer, Mansfield, Notts.

**Engine**, double oscillating horizontal, about half-horse, £6, a bargain.—JOURNET, 194, Great Portland-street.

**Metallizene** will make Chisels, Drills, &c., stand ten times the wear and durability of ordinary tools. Try it. Samples post free 12 stamps.—EDRIDGE, WILLMOTT, and Co., 27, Crown-street, Soho, London.

**Steam Launch**, 23ft. long, engine 4in. by 4½in. vertical boiler, propeller, all complete, £50.—CHENHALL, Eastville, Bristol.

**Fishing Bait.**—"Red Ching."—This celebrated Chinese bait received first prize Fisheries Exhibition. Will keep for years. Salt and fresh water fish, attracted from a long distance in large numbers by its peculiar odour and colour, take the bait voraciously. One packet will take bushels of fish. Post paid, 1s. 2d.—Agent, Dr. EVANS, Importer, Shirley, Southampton.

**Water Motors**, for sewing machines, organettes, window advertisements, 32s., 42s. List one stamp.—WHEELER.

**Fan Castings.**—Improved Registered Designs; sets 4in., 3s.; 6in., 4s.; 8in., 5s. Drawings, 4d.—WHEELER, Engineer.

**Water Motors.**—Complete one horse-power, £9. Half, £6; Quarter, £4; Eighth, £3.—THOMAS WHEELER, Preston.

**View Lens**, single, by A. Ross, price 30s., genuine, covers ¼-plate.—LENS, 1, Kilburn-square, N.W.

**Braun's Pocket Tripod Stand.** The smallest in the world, yet rigid and opens full size.

**Braun's Pocket Tripod Stand**, fits with metal top into box, 3¾in. square by 2in. deep.

**Braun's Pocket Tripod Stand**, sent carriage free for 17s. 6d.—BRAUN and Co., 119, High-road, Kilburn, N.W.

**Braun's Pocket Tripod Stand** is the thing for lady photographers, tourists, surveyors, and others. Patent applied for.

**Galvanometers**, 2s. 6d. Ditto Delicate Astatic, 5s. Ditto, Tangents, with glass shade, 10s. Am-meters, 5s. Voltmeters, 5s.—BOTTONE.

**Wheatstone's Bridges**, 5s. Standard Ohms, 2s. 6d. Standard Daniell's Cells, in box, for exact measurements, 5s. each.—BOTTONE.

**Wimshurst's** 12in. **Glass Plates**, fitted with spindles ready for mounting, 6s. per pair.—S. BOTTONE, Stanley-road, Carshalton.

**French Polishing**, Staining, Painting, and Varnishing. 122 recipes or trade secrets, with full instructions and details, post free, 1s.—TOMLIN, Highfield-terrace, Barnsley, Yorkshire.

Bench **Drilling Machine Castings**, complete, 3s. 6d.—TOMLIN, Highfield-terrace, Barnsley, Yorkshire.

Half horse-power Horizontal **Engine Castings**, (complete), brasswork and forgings, 12s. 6d.—TOMLIN, Highfield-terrace, Barnsley, Yorkshire.

Model **Engine Castings**, all brass, complete, 2s. 6d. set.—TOMLIN, Highfield-terrace, Barnsley, Yorkshire.

**Designs**, Price List of perfected Engines and Castings, 1 stamp.—TOMLIN, Engineer, Highfield-terrace, Barnsley, Yorkshire.

**Vallisneria Spiralis**, good healthy plants, with instructions. Price, 1s. 6d.—E. CARTER, 134, Dacy-road, Liverpool.

**Oxygen Gas**, compressed in cylinders, handiest and safest for limelight.—CLARKSON, Compressed Gas Chemist, Bartlett's-buildings, E.C.

**Oxygen Gas**, compressed into iron bottles, liquid nitrous oxide and carbonic acid.—CLARKSON, Compressed Gas Chemist.

**Oxygen Gas**, compressed into iron bottles; prices on application.—CLARKSON, 28, Bartlett's-buildings, Holborn, E.C.

Astronomical **Telescopes** of all kinds and Apparatus or Fittings made by A. CLARKSON, 28, Bartlett's-buildings.

**Eyepieces.**—Huyghenian of any power to fit any telescope, 15s. each. Sun Diagonals, £1. Star Diagonals, 30s.

Astronomical **Telescopes**, second-hand, by best makers.—CLARKSON, 28, Bartlett's-buildings, Holborn, E.C.

**Formulas Worked Out** for winding Dynamos, from 10 c.-p. to 500 c.-p., 8 stamps each.—H. JONES.

**Price List** of Dynamos in the rough and finished, speed, wire, required, notes, volts, amps., one stamp.—H. JONES.

Jones's **Patent Double Armatures**, low speed; any kind machines repaired.—H. JONES, 48, High-street, Lambeth, S.E.

**Incandescent Carbon Lamps**, low resistance, 3s. each. Fairy Lamps, 3s. 6d. Platinum Lamps, 1s. 3d., post free.—TODD, 14, Wentworth-road, Manor Park, Essex.

**Erythroxylon Coca.**

**The Sacred Leaf.**

**Coca Leaves.**—The best, safest, and cheapest stimulant. Consignment of choice quality just received.—MARKS and Co.

For the **Marvellous Benefits** to be derived from Coca, see last week's *Family Doctor* on the "Possibilities of Coca."

**Coca.** Sample packet, with medical and scientific opinions, 13 stamps.—MARKS and Co., 17, Newcastle-street, Farringdon-street, E.C.

**Clock Movements**, Wheel-cutting, Brass Turning. Finishing, Brass Casting, from 7½d. to 10d. per lb. Best.—The SCIENTIFIC INSTRUMENT STEAM-POWER WORKS, Victoria Bridge, Salford.

Drawing-room **Astronomical and Day Telescope** (Beck), 2¾ o.g., by Cooke, 4 eyepieces, mahogany case, cost £30, price £12 10s.—CLARKSON, Telescope Maker, Bartlett's Buildings, Holborn, E.C.

**Microscopic Slide Cabinet**, holds 1,000 flat, glass door, excellent condition, 45s.—T., 35, Alexander-road, Holloway.

**Electromotor Gramme Ring**, handsomely finished, 25s.—J. SUTCLIFFE, 4, New Lorne-street, Moss Side, Manchester.

**Indiarubber Stamps.** Latest novelties. Splendid workmanship. Satisfaction guaranteed. Designs, 1d. stamp.—PASHLEY, 180, London-road, Sheffield.

Small **Gas Engines**, simple, strong, good and cheap. Numerous references.—ELLIS BUTTERWORTH, Rochdale.

"**Warne's Sheet Metal Worker**" to be sold, cheap, covers soiled.—94, St. Augustine's-road, Camden-square.

**Prizes to Amateur Mechanics.**—Five pounds will be given to maker of best Model Launch Engine, double cylinder, Castings, 5s., post free, 5s. 9d. Working Drawing (coloured) 9d. Send stamp for full particulars.

**Steam Pump Castings**, new design, all brass, no flywheel or eccentric required; cylinder ¾in. bore, 1in. stroke, post free, 3s. 6d. Working Drawing, 6 stamps.

**Send for Catalogue, 2d.** Six Lithographed Designs, 3d.—HUGHES' Mersey Dockyard, 17, Smith-street, Kirkdale, Liverpool.

Erasmus Wilson's **Sulpholine Lotion**, Judson's Artist's Black. Coaguline. Recipe, 7d. Three, 13d.—STANLEY, 119, Manchester-road, Poplar.

**Lathe**, self-acting, 6in. by 72in., and change wheels, £10 10s. Another, not self-acting, 4½in. by 42in., £5 10s. Combined Engine and Boiler, 3-horse, £21. Cash and exchange.—47, Charles-street, West Bromwich.

**Theodolite**, first-class 6in., upper and lower telescopes, 30-guinea instrument. What offers?—LINSCOTT, Ramsgate.

**Objectives**, by Watson, 2in., 1in., and ½in., for £4.—PARR.

**Objectives.**—1-7in. (Dancer), 1-12in. immersion (Swift), quite new, £5 5s.—PARR.

**Microscope**, £1, two powers; Lucerne Microscope, four powers, great curiosity, £1 10s.—PARR.

**Microscopical Slides, Books**, &c. Apply at once.—J. E. PARR, Ainsworth, Bolton.

**Bichromate Batteries**, half pint, 2s. 3d.; pint, 4s. 6d.; quart, 6s. 6d. Other sizes at intermediate prices.—S. MOSS, 67, Ryle-street, Macclesfield.

**Lathe**, engineer's, 6in. centre, 4ft. bed, excellent compound slide-rest, face-plate, bell chuck, tool tray, £10.—759, Old Kent-road, S.E.

**Leclanche Batteries**, six No. 2, perfect, unused, 3s. 6d. size, 13s. 6d. lot.—759, Old Kent-road, S.E.

Powerful **Medical Coil**, with batteries complete, quite new; cost 60s.; price 25s.—759, Old Kent-road.

**Dorrington's Steam Tricycle.**—See Testimonial in last week's "MECHANIC." Complete Working Drawings, 10s. Lithograph, 6 stamps.

**Dorrington's Steam Tricycle** can be worked by foot power. Engine and Boiler is self-contained, and can be used for any purpose.

**Complete Materials** for making Dorrington's Steam Tricycle can be obtained in separate lots if desired.—A. DORRINGTON, West Gorton, Manchester.

The **Amateur's Gas Engine.** Castings, 42s. Drawing, 5s. Litho, 3 stamps. Fitted up complete, £10.—A. DORRINGTON, West Gorton, Manchester.

**Launch Engine Castings**, 2in. cylinder, 12s. 6d.; 3in., 26s.; 4in., 50s.; 5in., 70s. Litho, 3 stamps.—A. DORRINGTON, West Gorton, Manchester.

**Electro-Dynamic Engine**, 12in. armature. Castings, 18s. Drawing, 5s. Litho, 3 stamps.—A. DORRINGTON, West Gorton, Manchester.

3 or 4 Jaw **Chuck Castings**, 3s. Forgings, 1s. 2d. Drawing, 6 stamps.—A. DORRINGTON, West Gorton, Manchester.

**Lathe Planing Attachment**, suit 5in. to 7in. Lathe. Drawing, 12 stamps.—A. DORRINGTON, West Gorton, Manchester.

**Double Cylinder Horizontal Engine**, cylinders 2in. by 3½in. Complete Castings, 21s. Litho, 3 stamps.—A. DORRINGTON, West Gorton, Manchester.

**Bench Drilling Machine Castings**, No. 1 size, 3s. 9d. Drawing, 8d. No. 2, 7s. 6d. Drawing, 1s. 6d.—A. DORRINGTON, West Gorton, Manchester.

4½in. **Fan Castings**, 3s. 6d. per set, including drawing. Drawing separate 4 stamps.—A. DORRINGTON, West Gorton, Manchester.

**Combined Fret Saw and Drill**, with bevel table. Castings, 10s. Drawings, 1s. 6d.—A. DORRINGTON, West Gorton, Manchester.

**Dorrington's World-renowned Castings** and DRAWINGS. List, 1 stamp.—A. DORRINGTON, West Gorton, Manchester.

**Lathe**, 5in. centre, treadle, 42in. bed, all iron, hand-rest, &c., 65s. Governors, 2-h.p., 15s. 6in. funnelling, cheap.—BRAGG, 93, Manor-street, Clapham.

**Gas Engine**, Six H.-P. Otto, by Crossley's, in first-rate condition, price £150.—Can be seen at 96, King's-road, Camden-road, N.W.

**Universal Trade** and Amateur Supply.—Lecture requisites; light, heat, air, water, geology, engineering, chemistry, photography, &c. Wholesale and export.—CAPLATZI.

**Unique Establishment** in London for Professionals, Amateurs. Main features—Universality, Reliability, and Cheapness. Beware of unqualified imitators.

**Specialities.**—Spark Coils, Batteries, Electric Motors, Working Pumps, Lathes, Saws, Hammers, Wheels of Life, Vacuum Tubes, Cannons, Fusees.

**Important.**—Parts, Fittings, Prepared Materials for Construction, Matching, Completing, Altering all kinds of Scientific Instruments, Collections, &c.

**Electric Machine**, Coil, Dynamo, Magic Lantern, Telescope, Spectroscope, and Lathe Makers will find thousands requisites uncommonly cheap.

**Organ Bellows**, Pipes, Cornet Stops, Keyboards, Reed Pans, Reeds, Concertinas, Harmoniums, Violins, Flutes, Clarionets, Lutes, &c.

Frictional and **Induction Machines**, Plates, Cylinders, Stands, Conductors, Glass, Vulcanite. Hundreds of Lecture Accessories. Their parts.

**Coils.**—Experimental, Resistance, Medical, Dynamo, Bell, Telegraph. Galvanometer and other purposes. Vacuum Tubes.

**Batteries.**—Thousands lighting, experimenting, medical, depositing. The Universal Four-Cell Case, 15s. Convenient, durable, and economical.

**Dynamos**, Arc and Glow Lamps, Electric Lanterns Castings, 10 kinds of Motors, Leads, Armatures, Dynamometers.

**Magnets.**—Most powerful Electros and Permanent for Fields, Magnetos, Bells, Galvos, Diamagnetism, Solenoid. Experiments generally.

**Wires.**—Cheapest Stores. New and second-hand Great reduction in price. Paraffin, Vulcanite, Reels, Brasswork Cores, various.

**Rare Metals.**—Potassium, Sodium, Magnesium Aluminium, Cobalt, Gold, Silver, Anodes, Nickel Salts, Depositing Apparatus, Moulds, Powders.—CAPLATZI.

**Lenses**, Prisms, Specula, Object-Glasses, Eyepiec Finders, Cells, Tubing, Racks, Hooks, Joints, Optical Glass. To in quantities.

Catalogue, 2d. **Caplatzi**, Science Depot, Hire a Exchange, Chenies-street, Tottenham Court-road, near Br Museum. Established

What offers for **English Mechanic**" from V XXIV. to present date, quite clean, unbound.—J. INGHAM, Cuthbert-street, Hall Park, Paddington.

**Mechanical Tools** (various). Fret Saws, best, dozen, wood 6d. foot, machines and frames.—J. PAYNE and Co., Cullum-street, E.C.

**Complete Instructions to Stain Wood.** imitate "mahogany," "satin wood," "rose wood," canary colour wood and ebony; also genuine receipt for French polish. The post free, 13 stamps.—C. MARSTON, 73, Allhallowgate, Ripon.

**To Anti-Tetotalers.**—Clear Instructions to p duce whisky, gin, brandy, and rum, without distillation; cost and no risk; all for 13d.—C. MARSTON, 73, Allhallowgate, Ripon.

**Dynamos**, from 10-light upwards, warranted, che sent on approval; some second-hand machines in stock.—WARN

**Write for Lists, &c.** Testimonials from all par WARNE, 39, St. John's-street-road, E.C.

**Lathe Head**, 3in. back-geared, poppet, 2ft. 6in. b new, £4.—BLANCHARD, 29, Earl-street, Lisson-grove, London.

**Gramme Ring**, 6 by 4, wound, 15s. H Armatu 4 by 2, 9s. Field-magnet, ditto, bored, 8s.—TOLMAN.

Tolman's original **Electric Motor** (recently scribed by E. Chaster), with armature 3 by 1, 30s.—TOLMAN.

**Dynamo Machine, and Arc Lamp** (50 volts amperes), 2,000 candle-power, £20, complete.—TOLMAN, W hampton.
